3. In the transition from one reflex to another a final common path changes hands and passes from one master to another. A fresh set of afferent arcs becomes dominant on the supersession of one reflex by the next. Of all the conditions determining which one of competing reflexes shall for the time being reign over a final common path, the *intensity* of reaction of the afferent arc itself relatively to that of its rivals is probably the most powerful. An afferent arc that strongly stimulates is *caeteris paribus* more likely to capture the common path than is one excited feebly. A stimulus can only establish its reflex and inhibit an opposed one if it have intensity. This explains why, in order to produce examples of spinal inhibition, recourse has so frequently been made in past times to *strong* stimuli. A strong stimulus will inhibit a reflex in progress although a weak one will fail. Thus in inhibition of micturition in the "spinal" dog a *forcible* squeeze of the tail will do it, but not a weak squeeze. So, likewise, any condition which raises the excitability and responsiveness of a nervous arc will give it power to inhibit other reflexes, just as it would if it were excited by a strong stimulus.

Crossed reflexes are usually less easy to provoke, less reliable of obtainment, and less intense than are direct reflexes. Consequently we find crossed reflexes usually more easily inhibited and replaced by direct reflexes than are these latter by those former. Thus the crossed stepping-reflex is easily replaced by the scratch-reflex, though its stimulus be continued all the time, and though the scratch-reflex itself is not a very potent reflex. But the reverse can occur with suitably adjusted intensity of stimuli.

Again, the flexion-reflex of the dog's leg is, when fully developed, accompanied by extension in the opposite leg. This crossed extensor movement, though often very vigorous, may be considered as an accessory and weaker part of the whole reflex, of which the prominent part is flexion of the homonymous limb. When the flexion-reflex is elicitable poorly, as, for instance, in spinal shock or under fatigue or weak excitation, the crossed extension does not appear. But, where the flexion-reflex is well developed, if not merely one but *both* feet be stimulated simultaneously with stimuli of fairly equal intensity, steady flexion at knee, hip and ankle results in *both* limbs, and extension occurs in neither limb. The contralateral part of each reflex is inhibited by the homolateral flexion of each reflex. In other words, the more intense part of each reflex obtains possession of the final common paths at the expense of the less intense portion of the reflex. But if the intensity of the stimuli applied to the right and left feet be not closely enough balanced, the crossed extension of the reflex excited by the stronger stimulus is found to exclude even the homonymous flexion that the weaker stimulus should and would otherwise evoke from the leg to which it is applied.

It was pointed out above that in a number of cases the transference of control of the final common path FC from one afferent arc to another is *reversible.* The direction of the transference can *caeteris paribus* be easily governed by making the stimulation of this receptor or that receptor the more intense. A factor largely determining whether a reflex succeed another or not is therefore intensity of stimulus.

4. A fourth main determinant for the issue of the conflict between rival reflexes seems the functional species of the reflexes. Reflexes initiated from a species of receptor apparatus that may be termed *noci-ceptive* appear to dominate particularly the majority of the final common paths issuing from the spinal cord. In the simpler sensations we experience from various kinds of stimuli applied to our skin there can be distinguished those of touch, of cold, of warmth and of pain. The pain ending may be regarded as adapted to a whole group of excitants, a group of excitants which has in relation to the organism one feature common to all its components, namely, a *nocuous* character.

With its liability to various kinds of mechanical and other damage, in a world beset with dangers amid which the individual and species have to win their way in the struggle for existence, we may regard nocuous stimuli as part of a normal state of affairs. The skin has evolved a *specific sense of its own injuries.* As psychical adjunct to the reactions of that apparatus we find a strong displeasurable effective quality in the sensations they evoke. This may be a means for branding upon memory, of however rudimentary a kind, a feeling from past events that have been perilously critical for the existence of the individuals of the species. In other words, if we admit that damage to such an exposed sentient organ as the skin must in the evolutionary history of animal life have been sufficiently frequent in relation to its importance, then the existence of a specific set of nerves for skin-pain seems to offer no genetic difficulty, any more than does the clotting of blood or innate immunity to certain diseases. That these nerve-endings constitute a distinct species is argued by their all evoking not only the same species of sensation, but the same species of reflex movement as regards "purpose," intensity, resistance to "shock," etc. And their evolution may well have been unaccompanied by evolution of any specialized end-organ, since the naked free nerve-endings would better suit the wide and peculiar range of stimuli, reaction to which is in this case required. A low threshold was *not* required because the stimuli were all intense, intensity constituting their harmfulness; but response to a wide range of stimuli of *different* kinds was required, because harm might come in various forms. That responsive *range* is supplied by naked nerve itself, and would be cramped by the specialization of an end-organ. Hence these nerve-endings remained free.

It is those areas, stimulation of which, as judged by analogy, can excite pain most intensely, and it is those stimuli which, as judged by analogy, are most fitted to excite pain which, as a general rule, excite in the "spinal" animal—where pain is of course non-existent—the *prepotent* reflexes. The nervous arcs of pain-nerves, broadly speaking, dominate the spinal centres in peculiar degree. Pain is thus the psychical adjunct of an imperative protective reflex. It is preferable, however, since into the merely spinal and reflex aspect of the reaction of these nerves no sensation of any kind can be shown to enter, to avoid the term "pain-nerves." Remembering that the feature common to all this group of stimuli is that they threaten or actually commit damage to the tissue to which they are applied, a convenient term for application to them is *nocuous.* In that case what from the point of view of *sense* are cutaneous pain-nerves are from the point of view of *reflex-action* conveniently termed *noci-ceptive* nerves.

In the competition between reflexes the noci-ceptive as a rule dominate with peculiar certainty and facility. This explains why such stimuli have been so much used to evoke reflexes in the spinal frog, and why, judging from them, such "fatality" belongs to spinal reflexes.

One and the same skin surface will in the hind limb of the spinal dog evoke one or other of two diametrically different reflexes according as the mechanical stimulus applied be of noxious quality or not, a harmful insult or a harmless touch. A needle-prick to the planta causes invariably the drawing up of the limb—the flexion-reflex. A harmless smooth contact, on the other hand,

causes extension—the extensor-thrust above described. This flexion is therefore a noci-ceptive reflex. But the scratch-reflex—which is so readily evoked by simple light irritation of the skin of the shoulder—is relatively mildly noci-ceptive. When the scratch-reflex and the flexion-reflex are in competition for the final neurone common to them, the flexion-reflex more easily dispossesses the scratch-reflex from the final neurone than does the scratch-reflex the flexion-reflex. If both reflexes are fresh, and the stimuli used are such as, when employed separately, evoke their reflexes respectively with some intensity, in my experience it is the flexion-reflex that is usually prepotent. Yet if, while the flexion-reflex is being moderately evoked by an appropriate stimulus of weak in-scratch-reflex from the final neurone than does the scratch-reflex is applied, the steady flexion due to the flexion-reflex is replaced by the rhythmic scratching movement of the scratch-reflex, and this occurs though the stimulus for the flexion-reflex is maintained unaltered. When the stimulus producing the scratch is discontinued the flexion-reflex reappears as before.

In decerebrate rigidity, where a tonic reflex is maintaining contraction in the extensor muscles of the knee, stimulation of the noci-ceptive arcs of the limb easily breaks down that reflex The noci-ceptive reflex dominates the motor neurone previously held in activity by the postural reflex And noci-ceptive reflexes are relatively little depressed by "spinal shock."

Besides those receptors attuned to react to direct *noxa,* the skin has others, concerned likewise with functions of vital importance to the species and colligate with sensations similarly of intense affective quality; for instance, those concerned with sexual functions. In the male frog the sexual clasp is a spinal reflex. The cord may be divided both in front and behind the brachial region without interrupting the reflex. Experiment shows that from the spinal male at the breeding season, and also at other times, this reflex is elicited by any object that stimulates the skin of the sternal and adjacent region. In the intact animal, on the contrary, other objects than the female are, when applied to that region, at once rejected, even though they be wrapped in the fresh skin of the female frog and in other ways made to resemble the female. The development of the reflex is not prevented by removal of the testes, but removal of the seminal reservoirs is said to depress it, and their distension, even by indifferent fluids, to exalt it. If the skin of the sternal region and arms is removed the reflex does not occur. Severe mutilation of the limbs and internal organs does not inhibit the reflex, neither does stimulation of the sciatic nerve central to its section. The reflex is, however, depressed or extinguished by strong chemical and pathic stimuli to the sternal skin, at least in many cases The tortoise exhibits a similar sexual reflex of great spinal potency

It would seem a general rule that *reflexes arising in species of receptors which considered as sense-organs provoke strongly affective sensation* caeteris paribus *prevail over reflexes of other species when in competition with them for the use of the "final common path."*

Of all reflexes it is those of ordinary posture that are the most *easily* interrupted by other reflexes. Even a weak stimulation of the noci-ceptive arcs arising in the foot often suffices to lower or abolish the knee-jerk or the reflex extensor tonus of the elbow or knee. If various *species* of reflex are arranged, therefore, in their order of potency in regard to power to interrupt one another, the reflexes initiated in receptors which considered as sense-organs excite sensations of strong affective quality lie at the upper end of the scale, and the reflexes that are answerable for the postural tonus of skeletal muscles lie at the lower end of the scale One great function of the tonic reflexes is to maintain habitual attitudes and postures. They form, therefore, a nervous background of active equilibrium. It is of obvious advantage that this equilibrium should be easily upset, so that the animal may respond agilely to the passing events that break upon it as intercurrent stimuli.

Results.—Intensity of stimulation, fatigue and freshness, spinal induction, functional species of reflex, are all, therefore, physiological factors influencing the result of the interaction of reflex-arcs at a common path. It is noticeable that they all resolve themselves ultimately into *intensity of reaction.* Thus, intensity of stimulus means as a rule intensity of reaction. Those species of reflex which are habitually prepotent in interaction with others are those which are habitually intense; those specially impotent in competition are those habitually feeble in intensity, *e g*, skeletal muscular tone. The tonic reflexes of attitude are of habitually low intensity, easily interfered with and temporarily suppressed by intercurrent reflexes, these latter having higher intensity.

The high variability of reflex reactions from experiment to experiment, and from observation to observation, is admittedly one of the difficulties that has retarded knowledge of them Their variability, though often attributed to general conditions of nutrition, or to local blood-supply, etc., seems far more often due to changes produced in the central nervous organ by its own functional conductive activity apart from fatigue. This functional activity itself causes from moment to moment the temporary opening of some connections and the closure of others. The chains of neurones, the conductive lines, have been, especially in recent years, by the methods of Golgi, Ehrlich, Apathy, Cajal and others, richly revealed to the microscope Anatomical tracing of these may be likened, though more difficult to accomplish, to tracing the distribution of blood vessels after Harvey's discovery had given them meaning, but before the vasomotor mechanism was discovered. The blood vessels of an organ may be turgid at one time, constricted almost to obliteration at another With the conductive network of the nervous system the temporal variations are even greater, for they extend to absolute withdrawal of nervous influence. Under reflex inhibition a skeletal muscle is relaxed to its post-mortem length, *i e*, there may then be no longer evidence of even a tonic influence on it by its motor neurone. The final common path is handed from some group of a *plus* class of afferent arcs to some group of a *minus* class, or of a rhythmic class, and then back to one of the previous groups again, and so on The conductive web changes its functional pattern with certain limits to and fro. It changes its pattern at the entrances to common paths The changes in its pattern occur there in virtue of interaction between rival reflexes. occlusion, substitution by equivalence, inhibition, immediate induction, successive induction, fatigue, are factors As a tap to a kaleidoscope, so a new stimulus that strikes the receptive surfaces causes in the central organ a shift of functional pattern of the linkage. The central organ is a vast network whose lines of conduction follow a certain scheme of pattern, but within that pattern the details of connection are, at the entrance to each common path, mutable. The grey matter may be compared with a telephone exchange, where, from moment to moment, though the end-points of the system are fixed, the connections between starting-points and terminal points are changed to suit passing requirements, as the functional points are shifted at a great railway junction. In order to realize the exchange at work, one must add to its purely spatial plan the temporal datum that within certain limits the connections of the lines shift to and fro from minute to minute An example is the "reciprocal innervation" of antagonistic muscles—when one muscle of the antagonistic couple is thrown into action the other is thrown out of action This is only a widely spread case of the general rule that antagonistic reflexes interfere where they embouch upon the same final common paths And that general rule is part of the general principle of the mutual interaction of reflexes that impinge upon the same common path. *Unlike reflexes have successive but not simultaneous use of the common path; like reflexes mutually reinforce each other on their common path* Expressed teleologically, *the common path, although economically subservient for many and various purposes, is adapted to serve but one purpose at a time Hence it is a co-ordinating mechanism and prevents confusion by restricting the use of the organ, its minister, to but one action at a time.*

In the case of simple antagonistic muscles, and in the instances of simple spinal reflexes, the shifts of conductive pattern due to interaction at the mouths of common paths are of but small extent. The co-ordination covers, for instance, one limb or a pair of limbs. But the same principle extended to the reaction of the great arcs arising in the projicient receptor organs of the head,

e.g., the eye, which deal with wide tracts of musculature *as a whole*, operates with more multiplex shift and wider ambit. Releasing forces acting on the brain from moment to moment shut out from activity whole regions of the nervous system, as they conversely call vast other regions into play. *The resultant singleness of action from moment to moment is a keystone in the construction of the individual whose unity it is the specific office of the nervous system to perfect.* The interference of unlike reflexes and the alliance of like reflexes in their action upon their common paths seem to lie at the very root of the great psychical process of "attention."

The spinal cord is not only the seat of reflexes whose "centres" lie wholly within the cord itself; it supplies also conducting paths for nervous reactions initiated by impulses derived from afferent spinal nerve, but involving mechanisms situate altogether headward of the cord in the brain. Many of these reactions affect consciousness, occasioning sensations of various kinds.

Besides the paths followed by headward-running impulses the spinal cord contains paths for impulses passing along it backwards from the brain. These paths lie almost entirely in the ventrolateral columns of the cord. The fibres of which they are composed cross but little in the cord. Their sources are various, some come from the hind brain and some from the mid brain, and in the higher mammalia, especially in man and in the anthropoid apes, a large tract of fibres in the lateral column (the crossed pyramidal tract) comes from the cortex of the neopallium of the fore brain. This last tract is the main medium by which impulses initiated by electrical stimulation of the motor cortex reach the moto-neurones of the cord and through them influence the activity of the skeletal muscles. Of the function of the other tracts descending from the brain into the cord little is known except that mediately or immediately they excite or inhibit the spinal motoneurones by various levels. How they harmonize one with another in their action or what their purpose in normal life may be is at present little more than conjecture. Such terms, therefore, as "paths for volition," etc., are at present too schematic in their basis to warrant their discussion here. (C. S. S.)

SPINAL MENINGITIS. Inflammation of the membranes (meninges) surrounding the brain and spinal cord. An equivalent term is cerebro-spinal meningitis.

The meninges, like the pleura, pericardium and peritoneum, are subject to infection with a wide variety of cocci and bacilli. According to the microbic incitant, the infection is termed tubercular, pneumococcal, streptococcal, staphylococcal, influenzal (*B. pfeifferi*), typhoid, etc., meningitis. The precise diagnosis is accomplished by means of the bacteriological examination of fluid (cerebro-spinal) withdrawn by lumbar puncture. The abovementioned class of bacterial infections of the meninges tends to arise sporadically; as a rule it accompanies the corresponding bacterial infection affecting other parts of the body, the lungs, middle ear, tonsils, etc.

Epidemic Form.—In sharp contrast with the sporadic varieties of meningitis is the epidemic form, incited by the diplococcus discovered by Weichselbaum in 1887, now called meningococcus, of which many epidemic outbreaks have been recorded. The meningococcus appears not as a single, sharply defined species, but as a group in which the composing strains, while showing many properties in general, are yet distinguishable by power to ferment carbohydrates, reaction to specific agglutinating agents, etc.

Certain strains of meningococci have greater virulence for man than others and the more virulent strains show greater fixity of biological properties. During epidemics of meningitis virulent strains have the wider distribution; while in interepidemic periods the weaker, less defined strains are more frequently encountered.

A pandemic of meningitis prevailed during the first two decades of the present century. It embraced Europe, America, Asia, Africa and many islands of the seas. This pandemic was characterized by high mortality and by those multiple clinical features which have been noted in previous severe epidemics of the disease. A part only of the cases, usually not a large part, was attended by the visible haemorrhages in the skin and mucous membranes to which the name of spotted fever was applied in earlier times. Usually the very severe and rapidly fatal so-called fulminating cases fell into this category.

The fatality of the epidemic outbreaks, whether in Europe, in America or in more distant countries, in the years between 1904 and 1910 did not vary greatly. In the United States the percentage figures were from 75 to 90; in Great Britain 70 to 80; in Germany 60 to 70; in France, Italy and Belgium 75 to 80; in Palestine 80; in Greece 60; in the Transvaal 75. In other words, the pandemic seems to have been little affected by locality or race. As in all previous epidemics closely observed, the mortality was influenced by the age period of the attacked; the very young and the very old rarely survived attack. Patients between 5 and 30 years of age have the best chance of recovery.

Serum Treatment.—The outlook for recovery has been greatly modified by the discovery and use of the antimeningococcic serum since 1904. Attempts to produce a curative serum were carried out simultaneously in Germany by Jochmann and Wassermann, and in America by Flexner. The former failed perhaps because the manner of use was wrong: the serum was injected chiefly subcutaneously. The latter succeeded, because repeated injections were made directly into the inflamed meninges by means of lumbar puncture. Flexner's method was based on an experimental study in which the meninges of monkeys were infected with the meningococcus, and the treatment was applied by lumbar puncture. The serum-treated monkeys survived, while the untreated and those treated by subcutaneous injections of the serum succumbed.

This result agrees with what is known of the anatomical-physiological conditions affecting the passage of chemical substances from the blood into the cerebro-spinal fluid. Such passage, even when the membranes are inflamed, takes place to a very small extent or not at all.

Results of Serum Treatment.—The consensus of competent opinion is that given a strong polyvalent antimeningitis serum, its proper employment is capable of greatly modifying the course of the disease, of reducing the mortality, and of preventing crippling consequences.

A number of tabulations have been published showing the effects of the serum according to age groups, days of first injection, etc. The largest compilation is that of Flexner, dealing with about 1,300 cases in which the mortality among those treated in the first three days of illness was 18·1, the second three days 27·2 and after the seventh day 36·5%. The total mortality among these cases was 30·8%, as compared with 75 to 80% among corresponding non-serum-treated cases. Netter's figures for the corresponding three periods are 7·14, 11·1 and 23·5%; and Dopter's 8, 20, 14·4 and 24·1%. Flexner's figures are compiled from the reports of physicians at many places, while Netter's and Dopter's are based on personal experiences largely. Similarly, the influence of age on the results of the treatment is shown as follows: According to Flexner, under one year 50%, one to 20 years 75%, over

20 years 60% recovered; according to Netter, under one year 40%, one to 20 years 79% recovered; and according to Dopter, under one year 53%, one to 20 years 78%, and over 20 years 76% recovered.

Certain important objective effects are produced when anti-meningitis serum is administered Perhaps the most immediately impressive is the modified character of the clinical course of the disease itself. Briefly stated, this relates to the essential disappearance of the chronic cases slowly moving through weeks and months to a fatal issue, attended by hydrocephalus, extreme emaciation and other sequels Either the cases fail to respond and terminate quickly, or in a few days the real infection is over and the patient convalescent. The growth and multiplication of the meningococcus within the cerebro-spinal fluid are quickly arrested Next, epidemic meningitis is a disease from which when recovery occurs spontaneously it tends to take place slowly, gradually, or by "lysis", under the influence of the serum, sudden termination by "crisis" frequently takes place Finally, the severe consequences, as of hydrocephalus, impairment of vision and mentality, paralysis and joint affections, are diminished The one severe complication which has not been influenced is deafness, which occurs in a varying, usually small percentage of the cases, and usually very early in the disease

Mode of Infection.—The meningococcus gains access to the interior of the body by way of the mucous membrane of the nose and throat. The incidence of meningitis bears relationship to the proportion of nasopharyngeal carriers of the meningococcus When the cases are few in any community or group of persons the carrier rate is low When the carrier rate rises the cases tend to increase in number. During sharp outbreaks, among an exposed personnel, the carrier rate may reach 20%; ordinarily it is 2 to 3% or less

Probably the meningococcus passes from the nasal mucous membrane into the blood, with which it is carried to the meninges Whether it ever passes along the direct lymphatic channels stretching from the nasal membrane to the meninges may be doubted Instances are known in which meningococci were present in the blood some time before signs of meningitis appeared The intravenous injection of the anti-meningitis serum has been successful in removing the microbe from the blood and of curing the general or blood infection No meningitis followed It is because of the occurrence of meningococci in the blood stream that early intravenous injection of the serum is recommended by certain authorities as a regular part of its intraspinal use in the treatment of epidemic meningitis To be of value, the intravenous injection should be carried out very early in the disease, and it should not be substituted for the direct injection into the inflamed meninges As a rule, a number of intraspinal serum injections on successive days is required to control the infection

The successful employment of the anti-meningococcus serum has led to efforts being made to control other microbic varieties of meningitis in a similar manner, but thus far without notable success

SPINDLE-TREE (*Euonymus europaeus*), so-called from its tough wood being formerly used for spindles, a small tree of the family Celastraceae, native to Europe and sparingly naturalized in eastern North America The wood furnished good charcoal. (*See* Euonymus; Wahoo.)

SPINEL, in mineralogy, the name given to a group of minerals, of the general composition $R''O \cdot R_2'''O_3$, where R''=Mg, Fe, Mn, Zn, and R'''=Al, Fe''', Cr''' The typical member is $MgO\,Al_2O_3$, a magnesium aluminate to which the name (Fr *spinelle,* from the Latin *"spina,"* perhaps in allusion to the sharp angles of the crystals) was originally restricted All spinels crystallize in the cubic system, typically in octahedra Twinning is common, the octahedral face being the twin plane, giving a characteristic form known as the spinel twin.

The group of spinel minerals includes the following members —

Magnesia-spinel	$MgAl_2O_4$	Magnesioferrite	$MgFe_2O_4$
Pleonaste	$(Mg,Fe)Al_2O_4$	Magnetite	$FeFe_2O_4$
Hercynite	$FeAl_2O_4$	Gahnite	$ZnAl_2O_4$
Picotite	$(Mg,Fe)(Al,Cr)_2O_4$	Franklinite	$(Zn,Mn)Fe_2O_4$
Chromite	$FeCr_2O_4$		

Cleavage is typically absent in these minerals with the exception of the zinc spinel (cleavage on 111), but an octahedral parting is observable in magnetite and franklinite The hardness is variable, in ordinary spinel 7·5–8, but magnetite H=6 and chromite H=5 5 The sp gr varies with the composition, from 3·6 (magnesia-spinel) to 5 2 (magnetite) The light refraction shows a range from 1 718 (pure $MgAl_2O_4$), hercynite 1 80, to picotite 2 05, chromite 2 10 and magnetite 2 42 Spinels vary much in colour. Magnesia spinels are pink, red and blue, and are used as gem-stones The pure magnesia spinel is colourless, hercynite is dark green in thin slices and picotite and chromite are brown in the thinnest sections Spinels are readily produced artificially Magnesia spinel melts at 2135° C and between this compound and $FeAl_2O_4$ there is complete miscibility as revealed in spinel analyses, but solid solution between $(Mg, Fe)Al_2O_4$ and magnetite is very limited The spinels used in jewellery are found mostly in gem gravels, the chief localities being Ceylon, Siam and Upper Burma.

Spinels occur both in igneous and metamorphic rocks. The home of the magnesia spinel is in thermally altered dolomites where it arises by reaction of alumina with dolomite Here it is usually accompanied by calcite and forsterite The iron-rich member, pleonaste, is common both in ultrabasic rocks such as dunites and in quartz-less argillaceous hornfelses and gneisses In these latter it is almost universally accompanied by cordierite and frequently by sillimanite, andalusite or corundum Hercynite is characteristic of the granulites of Saxony in association with garnet, sillimanite, etc The chromiferous spinel, picotite, is relegated to the ultrabasic rocks, as dunite, lherzolite and the serpentines derived from them Gahnite, the zinc spinel, occurs in schists associated with zinc ores, and in pegmatites in Finland and at Broken Hill, New South Wales, while franklinite is associated with zinc and manganese minerals in limestone at Franklin Furnace, New Jersey (*See* also Chromite, Magnetite)

(C E T)

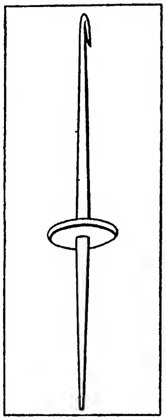
SPINELLO, ARETINO (*c* 1330–1410). Italian painter, the son of a Florentine named Luca, who had taken refuge in Arezzo in 1310 when exiled with the rest of the Ghibelline party, was born at Arezzo about 1330 Spinello was a pupil of Jacopo di Casentino, a follower of Giotto, and his own style was a sort of link between the school of Giotto and that of Siena In the early part of his life he worked in Florence painting frescoes, nearly all in terra verde in the churches, the Carmine, Sta Maria Novella and elsewhere These works are no longer extant Between 1360 and 1384 he was occupied in painting many frescoes in and near Arezzo, almost all of which have now perished After the sack of Arezzo in 1384 Spinello returned to Florence, and in 1387–1388 with some assistants covered the walls and vault of the sacristy of S Miniato near Florence with a series of frescoes, the chief of which represent scenes from the life of St Benedict Of his later works the chief are the very fine series of frescoes painted in 1407–1408 in the Salia di Balia in the Palazzo Pubblico at Siena, these are the finest of Spinello's existing frescoes Spinello died at Arezzo on March 14, 1410

See Sir Dominic Colnaghi, *Dictionary of Florentine Painters* (1928)

SPINET or **SPINNET,** names given in England to all small keyboard instruments irrespective of shape, having one string to a note, plucked by means of a quill or plectrum of leather The earliest name recorded for this instrument is clavicymbalum, which occurs in the rules of the Minnesingers (1404), and also in the *Wunderbuch* (1440), a ms preserved in what was formerly the grand-ducal library at Weimar (*See* Pianoforte)

SPINNING, the forming of threads by drawing out and twisting various fibres There is ample evidence of the great antiquity and wide diffusion of the art of spinning, for spinning necessarily precedes weaving (*q v*) whenever short fibrous materials

have to be made into threads, and weaving is one of the primal and most universal employments of mankind. No art which has been so long and widely practised remained so unprogressive as that of spinning. On the other hand, since about the middle of the 18th century, when human ingenuity bent itself in earnest to improve the art, there have not been developed in the whole range of mechanical industries machines of greater variety, delicacy of action and capacity than those now in use for spinning.



BY COURTESY OF L. HOOPER AND THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM

AN EARLY SPINDLE

Used in primitive thread-making, it was made of wood and was from 9in. to 15in. long

The primitive thread-making implement consisted of a wooden spindle, from 9 to 15in. long, which was rounded and tapered at both extremities, as in the accompanying figure. Near the top there was usually a notch in which the yarn was caught while undergoing the operation of twisting, and lower down a whorl, or wharve, composed of a perforated disk of clay, stone, wood, or other material was secured to give momentum and steadiness to a rotating spindle. Long fibres were commonly attached to a distaff of wood, which was held under the left arm of the operator, but short fibres were spun from carded rolls. After attaching some twisted fibres to the spindle, a rotatory motion was given to the latter either by rolling it by hand against one thigh, or by twirling it between the fingers and thumb of the right hand, after which the fibres were drawn out in a uniform strand by both hands and converted into yarn. When the thread was of sufficient strength, the spindle was suspended by it until a full stretch had been drawn and twisted, after which that portion was wound upon the body of the spindle, and the operation continued until the spindle was filled. The quantity thus rolled up gives the name to a now definite measure of linen yarn, namely "the spindle," or 14,400 yards. Simple as was this primitive apparatus, a dexterous spinner could produce yarn of an evenness, strength and delicacy such as has scarcely been exceeded by elaborate modern appliances. The yarns for the gossamer-like Dacca muslins of India were so fine that 1 lb. weight of cotton was spun into a thread nearly 253m. long. This was accomplished with the aid of a bamboo spindle not much bigger than a darning needle, and which was lightly weighted with a pellet of clay. Since such a tender thread could not support even the weight of so slight a spindle, the apparatus was rotated upon a piece of hollow shell. The spindle as here described was, so far as is known, the sole apparatus with which yarn was spun until comparatively recent times.

Modern Spinning.—Modern changes have had for their object: (1) the providing of mechanical means to rotate the spindle, (2) an automatic method of drawing out the fibres, and (3) devices for working a large group of spindles together, at rapid speeds.

The first improvement consisted in cutting a ring groove in the wharve, mounting the spindle horizontally in a frame, and passing a band from a large wheel round the wharve. A rotatory motion was then given to the spindle by turning the wheel with the left hand. After attaching the filaments to the spindle they were attenuated with the right hand, and when fully twisted the thread was moved to form a right angle with the spindle and coiled upon it. Such a wheel has long been known in India, and from a drawing in a 14th-century manuscript in the British Museum it is obvious that it was not unknown, although far from being in general use, in Europe at that early date. It came ultimately to be known in England as the "bobbing wheel," and was in constant use down to the beginning of the 19th century for spinning coarse and fine yarns. But fine yarns received two spinnings; the first consisted in drawing out and slightly twisting the fibres into what is still known as a roving, and by the second spinning the roving was fully attenuated and twisted. In 1533, a citizen of Brunswick is said to have cranked the axis of the large wheel and added a treadle, by which the spinner was enabled to rotate her spindle with one foot and have both hands free to manipulate the fibres.

It is not possible accurately to fix the dates at which all improvements in spinning appliances were made; it is certain that many were known and used long before they were generally adopted. Thus the flyer, which twists yarn before winding it upon a bobbin, is shown in a drawing by Leonardo da Vinci, together with a device for moving the bobbin up and down the spindle so as to effect an even distribution of the yarn. During the 16th century a machine of the foregoing type was widely used, and came to be known as the Saxony wheel. It changed spinning from an intermittent to a continuous operation. The spindle had affixed upon its outer end a wooden flyer, whose forked legs were far enough apart to enclose a double-flanged spool, and at short intervals bent wires, known as the heck, were inserted in each leg for the purpose of guiding the thread evenly upon the spool. This spool was loosely threaded upon the spindle and one of its flanges was grooved to take a driving band from the large wheel, hence the spindle and the spool were separately driven, but the former at a higher speed than the latter. The twisted filaments were drawn through an eye in the flyer, led along one of its legs, and made fast to the spool. By operating the treadle the flyer twisted all the fibres about a common axis once for each revolution, and the spool wound up the length thus spun: the thread being slipped from tooth to tooth of the heck at regular intervals to direct it evenly across the spool.

The remaining part of the problem which lay before inventors was to draw out masses of parallel fibrous material, and twist them into uniform strands by mechanical means. The first stage in the evolution of mechanical spinning was effected by the invention of Lewis Paul, of Birmingham, who obtained a patent in 1738, and who was assisted by John Wyatt. The essential features of this invention consisted in passing carded slivers between pairs of parallel rollers, each succeeding pair of which moved faster than the preceding pair, to attenuate the sliver to the required extent. From Paul's specification it would appear that he attempted to turn the rollers about their horizontal and vertical axes simultaneously, in order to draw out the fibres and twist them at one operation. But he also mentions a plan for which he procured a patent 20 years later, namely, the use of only one pair of rollers working in conjunction with a bobbin which drew off the thread faster than the rollers delivered the sliver, and coiled the thread about itself. The bobbin, therefore, attenuated, twisted and wound the material. Neither plan proved a commercial success. Thomas Highs, of Leigh, and others, laboured upon the problem, but it was left to Richard Arkwright, a barber, of Preston and Bolton, to achieve what his predecessors vainly struggled for. He obtained patents, in 1769 and 1775, for a machine which was subsequently known as the water-twist frame by reason of water-power being applied to drive it. Arkwright's first machine did not contain any really new feature, for it consisted of Paul's drawing rollers, and the spindle, flyer and spool from the Saxony wheel, but the spindles and rollers were grouped in sets of four. Later the water-twist frame was changed into the "throstle" frame, which in turn has almost ceased to be used. In 1829 C. Danforth (1797–1876), an American spinner, invented a dead spindle, on the top of which he placed a hollow cap to serve as the winding point, and inside the cap he rotated a spool: a plan still used by worsted spinners. In 1828 Mr. Thorpe, also an American, invented the ring spinning frame, whose principal feature consisted in the substitution for the flyer of a flanged annular ring, and a light C-shaped traveller. By means of the traveller a thread was held in the best position for winding upon a spool, as well as put under the necessary tension. Later inventors have so altered the construction of the ring, traveller and spindle that a speed of upwards of 11,000 revolutions per minute can now be attained. This represents the highest development of continuous spinning.

Whilst endeavours were being made to perfect continuous spinning, attention was also directed to perfecting the intermittent

process as represented by the bobbing wheel. Between the years 1764 and 1767, James Hargreaves, of Standhill, invented the spinning jenny, by the aid of which 16, or more, threads could be spun simultaneously by one person. All the spindles were placed vertically and rotated from a drum, but the rovings were mounted in a movable carriage and passed between a clamp that opened and shut like a parallel ruler. After securely clamping the rovings and attaching them to the spindles, the carriage was drawn out slowly by one hand and the spindles revolved by the other The rovings were thus stretched to the proper degree of tenuity, and sufficiently twisted. This was followed by the inward run of the carriage, when the stretch of spun threads was wound upon the spindles, and the operation repeated Hargreaves therefore returned to the first principles of spinning, viz, simultaneous drawing and twisting But although the jenny gave a greatly increased output, it was ill adapted for fine spinning During the years 1774 to 1779, Samuel Crompton, of Bolton, combined, in the mule, the drawing rollers of Paul with the stretching of Hargreaves. But his rollers did not fully attenuate the rovings before twisting them, as is the case with continuous spinning, neither was stretching alone relied upon. From its introduction this machine was able to spin finer and more elastic threads than any of its rivals, but for a time the preparation of suitable rovings was a source of great trouble The immediate consequence of the decision of the court of king's bench, in 1785, to throw open to the public Arkwright's preparatory machinery, was an enormous increase in the usefulness of the mule Since Crompton's time a host of inventors have laboured to render all parts of the mule thoroughly automatic; this has led to many changes and additions, but none of its essential features has been discarded The inventions of Paul, Arkwright, Hargreaves and Crompton are at the foundation of all modern systems of spinning, details regarding them are given in the article on COTTON: *Cotton-Spinning Machinery*. (T W. F)

SPINOLA, AMBROSE, MARQUIS DE LOS BALBASES (1569–1630), Spanish general, born in Genoa, then practically a protected state under the power of Spain The family of Spinola was of great antiquity, wealth, and power, and a rival of the house of Doria for authority within the republic Unsuccessful in a lawsuit against the Dorias, Spinola decided to advance the fortunes of his house by serving the Spanish monarchy in Flanders. In 1602, he and his brother Frederick entered into a contract with the Spanish government. It was a speculation in which Spinola risked the whole great fortune of his house Frederick, who was to form a squadron of galleys for service on the coast, was killed in action with the Dutch (May 24, 1603). Spinola's first landing in Flanders resulted in nothing definite and he returned at the end of 1602 for more men. On Sept. 29, 1603, he laid siege to Ostend and took it on Sept 22, 1604, winning thereby a high reputation among the soldiers of his time. A visit to the Spanish court at Valladolid, resulted in his being appointed commander-in-chief in Flanders The wars of the Low Countries consisted at that time almost wholly of sieges, and Spinola made himself famous by the number of places he took in spite of the efforts of Maurice of Nassau to save them

On the outbreak of the Thirty Years' War Spinola conducted a vigorous campaign in the lower Palatinate, and was rewarded by the grade of captain-general The most renowned victory of his career—the capture of Breda after a long siege (Aug. 28, 1624–June 5, 1625)—is the subject of the great picture by Velazquez, known as "Las Lanzas"; the portrait of Spinola is from memory The taking of Breda was the culmination of Spinola's career. The enmity of Olivares and the want of money paralysed his efforts. Appointed plenipotentiary and general in the war over the succession to the Duchy of Mantua, Spinola landed at Genoa on Sept. 19, 1629. In Italy, Olivares caused him to be deprived of his powers as plenipotentiary, and, broken down in health, he died on Sept. 25, 1630, at the siege of Casale.

See A. Rodríguez Villa, *Ambrosio Spinola* . . . (Madrid, 1905).
(D H)

SPINOZA, BENEDICTUS DE (1632–1677), Dutch philosopher and maker of lenses. The surname occurs in various forms: Espinoza, d'Espinoza, Despinoza, de Spinoza, and simply Spinoza. His first name was Baruch (Hebrew for "Blessed"); but, in accordance with the custom of the time, it was rendered into its Latin equivalent (*Benedictus*)

THE LIFE AND WRITINGS OF SPINOZA

Early Years (1632–1654).—Spinoza was born in Amsterdam on November 24, 1632 The house in which he first saw the light, and in which he passed his early years, occupied the site of what is now No 41, Waterlooplein His grandfather (Abraham) and his father (Michael) were Portuguese crypto-Jews, that is, descendants of Jews whom the Inquisition had compelled to embrace Christianity but who remained Jews at heart When the Netherlands revolted against Spain and the Spanish Inquisition, in 1567, and the Union of Utrecht decreed, in 1579, that "every citizen shall remain free in his religion," many crypto-Jews in Spain and Portugal turned their eyes to Holland in the hope of finding refuge there from their common oppressors The destruction of the Spanish Armada, in 1588, probably favoured schemes of escape. So in 1593 the first batch of Jewish refugees arrived in Amsterdam Among these early arrivals were Spinoza's father and grandfather They hailed from Vidigueira, near Beja, in the South of Portugal, but appear to have stayed for a while in Nantes (France) before settling in Amsterdam. Spinoza's mother came from Lisbon She died in 1638, when Spinoza was barely six years old

The Spinozas were fairly well-to-do merchants. Spinoza's grandfather was regarded as the head of the Amsterdam Jewish community from about 1628 onwards, and Spinoza's father was Warden of his synagogue on many occasions, also Warden of the Jewish School, and President of a Jewish Charity which granted loans free of interest Under the circumstances it may be assumed that Spinoza attended the school for Jewish boys, founded about 1638 The curriculum of this school is well known, so we have a sufficiently clear idea of Spinoza's early education The school hours were 8 till 11 A M and 2 till 5 P M The subjects were all Hebrew—the Old Testament, the Talmud, Hebrew Codes, and the works of Ibn Ezra, Maimonides, Crescas and others Outside school hours the boys had private lessons in secular subjects The vernacular used in the Jewish school and in Jewish homes was Spanish. Spinoza learned Latin from a German scholar, Jeremiah Felbinger, who may also have taught him German Spanish and Portuguese Spinoza learned from his father, Dutch from his environment, and he also knew some French and Italian. When exactly he learned mathematics and physics is not known There were plenty of Hebrew books dealing with these sciences, and the Jewish School had a good lending library, so that Spinoza may have commenced these studies during his school years. Hence probably his choice of the profession of a maker of lenses

Of Spinoza's teachers at the Jewish School the most eminent were Saul Morteira and Manasseh ben Israel. Morteira was born in Venice in 1596, and studied medicine under Montalto, the crypto-Jewish Court physician of Maria de Medici He came to Amsterdam in 1616, and in 1638 was elected presiding Rabbi of the Amsterdam synagogues Manasseh ben Israel was born in Lisbon in 1604 His father was one of 150 Jews whom the Inquisition condemned to the flames in 1605 They managed to save their lives at the expense of their fortunes, and fled at the earliest opportunity Manasseh's parents brought him to Amsterdam about 1606 In 1622 he became the youthful Rabbi of one of the Amsterdam synagogues (the "Habitation of Peace"). In 1627 he started a Hebrew printing press, and in 1640 he was appointed to one of the senior posts in the Jewish School

In March 1654 Spinoza's father died There was some litigation over the estate, as Spinoza's only surviving step-sister claimed it all. Spinoza won the lawsuit, but allowed her to retain nearly everything. Henceforth Spinoza had to fend for himself

Critical Years (1654–1656).—Spinoza was in his twenty-second year when his father died. His studies so far had been mainly Jewish. But he was an independent thinker and he had found more than enough in his Jewish studies to wean him from orthodox theology. In the Biblical commentary by Abraham Ibn

Ezra (1092–1167) one meets with many "a word to the wise" directing attention to some inconsistency in Scripture, to the post-Mosaic authorship of parts at least of the so-called "Five Books of Moses," or to the different authorship of the two parts of *Isaiah*. In the *Guide of the Perplexed* of Moses Maimonides (1135–1204) attention is drawn to various crudities in Biblical theology, and to the provisional character of certain Biblical ordinances. In the writings of Gersonides (1288–1344) rationalism encroaches on miracles and prophecy in an attempt to eliminate the element of supernaturalism. Already Maimonides had insisted on interpreting Scripture in such a way as to harmonize it with reason. Gersonides went further than that. He faced the possibility of a conflict between Reason and Revelation, and maintained that, in such an event, the Bible "cannot prevent us from holding that to be true which our reason prompts us to believe." Again, the popular conception of the world's creation out of nothing was denied by both Ibn Ezra and Gersonides, who believed in the eternity of matter. Maimonides also repudiated the belief that man is the centre of creation, maintaining that each thing exists for its own, not for man's, sake; he also suggested the relativity of good and evil. The Jewish Mystics had taught that Nature is animated. Crescas (1340–1410) ascribed extension to God, denied the validity of the conception of final causes (or the explanation of objects and events by reference to their alleged purposes), and, like Ibn Ezra, maintained a thoroughgoing determinism. Here was food enough for thought, and incentive enough for heresy.

Moreover, the tendency to revolt against mere tradition and authority was very much in the air since the Renaissance, and it affected young Jews as others. There was the tragic figure of Gabriel da Costa, or Uriel Acosta (1585–1640). A crypto-Jewish refugee from Oporto, in Portugal, he settled in Amsterdam. He was opposed to the belief in immortality, and to various Jewish rites, on the ground that they were not Biblical. He was excommunicated by the Jewish authorities, recanted, then returned to the charge, was excommunicated again, recanted again under humiliating conditions, and shot himself. In his naturalistic outlook he was a forerunner of Spinoza. Especially interesting for the understanding of Spinoza is the case of another Jewish doctor of Amsterdam—Daniel de Prado (d. 1663). He too was opposed to supernaturalism and traditionalism, and appears to have influenced young people to adopt similar views. He was persuaded to recant in the synagogue in 1656, but there was no material change in his attitude. The synagogue authorities tried to bribe him to go abroad, but he declined, and was excommunicated in 1657. A contemporary poet, punster and protector of the faith (Isaac Orobio de Castro) wrote an invective in verse against de Prado as a philosophaster who led astray young students, Jewish and non-Jewish. Some of the allusions in this invective most probably refer to Spinoza, the record of whose excommunication faces the page in the communal minute book on which de Prado's recantation is recorded. Some of the writings of Jewish authors of the period (Samuel da Silva, Manasseh ben Israel, Orobio de Castro, etc.) in defence of immortality, revelation and tradition afford considerable evidence of the intellectual ferment in Amsterdam Jewry. And the religious leaders of the day were not particularly tactful or tolerant. They were alarmed by heresies which were at least as anti-Christian as anti-Jewish, and were afraid of giving offence in a country of which they were not yet regarded as citizens. This alarm shows itself in the attempt to bribe de Prado and Spinoza into silence. But they were also imbued with something of the intolerant spirit of the Inquisition, whose victims they had been. In 1640, they actually put the ban on Manasseh ben Israel for some trivial reason, though they rescinded it soon afterwards.

The views which brought Spinoza into collision with the synagogue authorities were essentially the same as those of Farrar, Acosta and de Prado. In conversation with other students he told them that there is nothing in the Bible to support the views that God has no body, that there really are angels (as distinguished from merely imaginative visions of them), and that the soul is immortal. He also expressed his belief that the author of the Pentateuch was no wiser in matters pertaining to physics or even theology than they were. These utterances were reported to the Jewish authorities, who after vainly trying to silence him with bribes and threats excommunicated him in July 1656. The fact of his excommunication was formally reported to the civil authorities—a gesture intended to absolve the Jewish community from all responsibility for Spinoza's heresies. And Spinoza was banished from Amsterdam for a short period.

There is no evidence that Spinoza really wanted to break away from the Jewish community. Such evidence as there is rather points the other way. On December 5, 1655, he attended service in the synagogue and made an offering. In view of his impecuniosity, offerings must have been rare events for him, and it may be assumed that he also went to the synagogue after that date, certainly in March 1656, the anniversary of his father's death. Shortly before or after his excommunication he also addressed an *Apology* (or defence of his views) to the synagogue authorities. Apparently he was not entirely indifferent to their opinions of him. Possibly if Manasseh ben Israel had not been away in London at the critical time, the whole storm would have blown over. As it was, tactlessness, mischief making, alarm and intolerance were in the saddle and rode for a fall. In his 24th year Spinoza stood alone, but unafraid, and uplifted by his destiny to become one of the great lights of humanity.

Years of Re-Orientation (1656–1660).—Already before his estrangement from the synagogue Spinoza had become acquainted with a number of Christians. Among these was a certain Francis van den Enden, an ex-Jesuit and ex-bookseller, but an ardent classical scholar and something of a poet and dramatist, who opened a school in Amsterdam in 1652. For a time Spinoza stayed with Van den Enden, assisting with the teaching of the school children, and receiving help in his own further education. In this way Spinoza improved his knowledge of Latin, learned some Greek, was introduced to the Neo-Scholastic philosophy of such writers as Burgersdijck (d. 1632) and Heereboord (d. 1659), and possibly also to the works of Descartes. In any case Spinoza's other Christian acquaintances were mostly Collegiants who were especially interested in the "new philosophy" of Descartes. At the same time he was learning the science and art of making lenses, in which he became a great expert. After his excommunication Spinoza spent some weeks, or possibly months, at Ouwerkerk, a village south of Amsterdam, and then returned to his native city, where he stayed until 1660. He supported himself partly by grinding and polishing lenses for spectacles, telescopes and microscopes, and partly by helping various people with their private studies. Holland was a country of many religious sects whose friction with the predominant Calvinist clergy imparted considerable vitality to theological problems and connected philosophical questions. As all these reformation movements were, or professed to be, "back to the Bible," a knowledge of Hebrew was felt to be necessary, and Hebrew experts like Spinoza were in some demand. The same was true of philosophy as an aid to theology. Accordingly, a number of amateur theologians secured the services of Spinoza to help them with their studies, and through them he also came into contact with others. Of his friends and acquaintances during this period the most important were Pieter Balling, Jarig Jelles, Lodewijk Meyer, Simon Joosten de Vries, and Jan Rieuwertsz. The sincerity of Simon Joosten de Vries's admiration for Spinoza was shown in many ways. At one time he pressed Spinoza to accept a gift of 2,000 florins, at another time he wanted to make Spinoza his sole heir, but in vain. By his will he left Spinoza an annuity of 500 florins, but Spinoza would not accept more than 300. Some or all of these and certain others formed a kind of reading and discussion circle for the study of religious and philosophical problems under the guidance of Spinoza. At first, we may assume, Cartesian philosophy played an important part in these discussions. For at that time there was something like a coalition between the "new philosophy" and liberal, dissenting theology, for they were both opposed by the dominant Calvinists. Most of his Collegiant friends remained Cartesian to the end, though Spinoza himself never followed Descartes in anything

except his science.

To judge from the opening passage of his *Treatise on the Improvement of the Understanding,* which was written shortly afterwards, the years 1656 to 1660 must have been years of storm and stress in Spinoza's mental history Cut off from kith and kin, and left stranded as the result of his honest attempt to think independently, worldly aims must have seemed at times more alluring than the beck of the spirit But his higher self won through, partly perhaps with the help of the faith which his unsophisticated friends and disciples placed in knowledge and in him His new orientation was accomplished by the end of this period. He had learned to view life and its problems from other angles than those of his native environment, and he had acquired a knowledge of a language and a system of concepts more suitable to serve as a vehicle for the great thoughts that were taking shape in his mind, and more suitable, too, for the wider influence which they were destined to exercise What he needed now was peace and quiet in which to collect his thoughts and reduce them to system He withdrew accordingly to Rijnsburg, a quiet unworldly village on the old Rhine, about six miles from Leyden

Life at Rijnsburg (1660–1670)—Rijnsburg was the headquarters of the Collegiants Arrangements for his stay there were no doubt made by his Collegiant friends He lodged with a surgeon named Hermann Homan, whose humanitarianism is obvious from the inscription on the cottage wall.

> Alas! if all men were but wise,
> And would be good as well,
> The Earth would be a Paradise,
> Where now 'tis mostly Hell.

(From Kamphuysen's *May Morning*) In this cottage (now *Het Spinozahuis*) Spinoza wrote his *Short Treatise on God, Man and his Well-being,* the *Treatise on the Improvement of the Understanding,* the greater part of his *Geometric Version of Descartes' Principia* with the appendix on *Metaphysical Thoughts,* and the first book of his *Ethics*. Part of the *Short Treatise* consists of notes which he had prepared in connection with the study circle in Amsterdam This circle continued to meet after Spinoza's departure from Amsterdam, and periodically Spinoza sent them the various parts of his *Short Treatise* and other works for study and discussion This is clear from Letters VIII and IX (*The Correspondence of Spinoza,* pp 101 *seq*) and from the closing sentences of the *Short Treatise* (pp 149 *seq* in A Wolf's edition). The *Short Treatise* and the *Treatise on the Improvement of the Understanding* were ready in or before April 1662, and were originally intended to be one work, as is clear from Spinoza's third letter to Oldenburg (*Correspondence,* pp 98 *seq*) Already in these earlier writings Spinoza's attitude is anti-Cartesian

During his stay in Rijnsburg Spinoza met various interesting people. Especially noteworthy are Steno, the founder of modern geology, and Oldenburg, one of the first two secretaries of the Royal Society of London Steno subsequently turned Roman Catholic and tried to persuade Spinoza to do likewise (see *Correspondence,* pp 324 *seq*); but he has the merit of having recognized in Spinoza "the reformer of the new philosophy" Oldenburg is of special interest in a biography of Spinoza because the most important part of Spinoza's correspondence passed between him and Oldenburg Oldenburg visited Leyden in 1661. His countryman Coccejus was professor there Spinoza must have acquired a reputation somehow, for Oldenburg went out of his way to visit him in Rijnsburg. The deep impression which Spinoza made on Oldenburg (who was about 18 years older than Spinoza) is evident from his first letter to Spinoza (see *Correspondence,* pp 73 *seq.*). In Rijnsburg also Spinoza first met the brothers Koerbagh whose subsequent tragic fate showed how little freedom of thought there really was even in Holland. Casearius, another student at the University of Leyden, came to spend a year or so in Rijnsburg, and stayed in the same cottage as Spinoza, who instructed him in the philosophy of Descartes. For this purpose Spinoza made a geometrical version of the second part of Descartes' *Principia*. While on a visit to Amsterdam, in 1663, Spinoza showed this to his Cartesian friends, who persuaded him to do the same with the first part of the *Principia* He did so in a fortnight These two parts, together with an appendix called *Metaphysical Thoughts,* were accordingly published by his friends in 1663 L Meyer wrote the introduction explaining that Spinoza did not really share the views expressed in the book; J Rieuwertsz was the publisher, and J Jelles defrayed the cost This was the only book published in Spinoza's life-time with his name on the title-page P Balling prepared a Dutch translation of this book, and published it in 1664

Early in 1662 Spinoza had completed the first draft of his philosophy in one work combining the *Short Treatise* and the *Treatise on the Improvement of the Understanding* He was not satisfied with its style or with its method of exposition He had tried the dialogue form without success, so he tried the geometrical method, in the manner of Euclid's *Elements,* which gave him more satisfaction He therefore decided to lay aside his earlier attempts and make a new start Thus originated his *Ethics*, the first book of which was finished, and in the hands of his friends, early in 1663 The title of the whole work was not yet intended to be *Ethics,* but "On God, the Rational Soul, and the Highest Happiness of Man" and the work was planned in three parts corresponding to the three parts of the title, instead of the five parts into which it eventually developed The publication of his version of Descartes' *Principia* was intended to prepare the way for the publication of his own philosophy For this purpose two things were necessary He had to secure the patronage of influential men who could shield him and his book from the remorseless hostility of the Calvinist clergy and other fanatics, and he had to show to the more philosophically minded people, who were mostly Cartesians, that his rejection of Cartesianism was not due to ignorance (see *Correspondence,* pp 123 *seq*, and *The Oldest Biography of Spinoza,* pp 57 *seq*, 147 *seq*) Spinoza appears to have succeeded so far as to win the interest of a few people belonging to the governing class These afforded him some protection, but not sufficient to enable him to publish his philosophy in his life-time Among these were J Hudde (who subsequently became Sheriff and then Burgomaster of Amsterdam, and a member of the States of Holland), H Boxel (Pensionary of Gorkum), C Burgh (who became Treasurer General of the United Netherlands in 1666), possibly also C van Beuningen (at one time Burgomaster of Amsterdam) and Jan de Witt (Grand Pensionary of Holland)

In June 1663 Spinoza moved from Rijnsburg to Voorburg, near The Hague Here Spinoza got to know Vossius the philologist, who was subsequently appointed Canon of Windsor, and Christian Huygens, the discoverer of Saturn's rings, inventor of the pendulum clock, and originator of the undulatory theory of light

Though busy with his *Ethics* and his lenses, Spinoza kept up his correspondence with various people, especially with Oldenburg Oldenburg kept Spinoza informed of the doings of the Royal Society (which had obtained its charter in July 1662) and of the researches of Robert Boyle and others, and solicited news from Spinoza about Huygens and others But about 1665 the correspondence was interrupted The Great Fire of London (1666) and the continuation of the war were no doubt responsible for this In 1667 Oldenburg was suspected of espionage and clapped into the Tower of London for a time He was released, but became nervous and cautious, so that his correspondence with Spinoza was not resumed until 1675

From a letter written in June 1665 it appears that Spinoza was then nearing the completion of his *Ethics* (*Correspondence,* p 202) In the following August or September, however, Spinoza informed Oldenburg that he was engaged on a theological treatise (see *Correspondence,* pp 204, 206) During the next few years Spinoza was at work on his *Tractatus Theologico-Politicus,* which was published anonymously in 1670 Why did he put aside his *Ethics* in order to write a treatise on the Scriptures? The chief reason is stated on the very title-page of the *Tractatus,* which states that its object is "to show that not only is perfect liberty to philosophize compatible with devout piety and with the peace of the State, but that to take away such liberty is to destroy the public peace and even piety itself" Already in 1665 Spinoza

mentioned this object to Oldenburg. But he also mentioned another, namely, he wanted to clear himself of the charge of atheism which had been brought against him. It would appear that, with the completion of the *Ethics* in sight, Spinoza was considering the question of its publication, but found that such a step was impracticable in the then state of public opinon, which under the increasing influence of the clerics and monarchists became very intolerant and restive, as the troubles caused by the war multiplied. Spinoza consequently conceived the plan of vindicating the cause of freedom of thought in a manner that would at once serve the general interest of the Republic and also prepare the way for the publication of his own philosophy. The chief obstacle was the Calvinist clergy with their constant appeal to Scripture, which they interpreted in any manner that served their fanaticism. So Spinoza set himself the task of showing that the Bible, properly understood, gives no support to the intolerance of the clerics and their interference in civil and political affairs.

Last Years (1670–1677).—In May 1670, shortly after the anonymous appearance of the *Tractatus Theologico-Politicus,* Spinoza moved into The Hague, possibly in order to be nearer some of his influential friends. He certainly needed protection. His book created a stir, and went through five editions in as many years. But it stirred a hornet's nest, and denunciations came fast and furious. At first Spinoza stayed on the *Stille Veerkade,* but in 1671 he went to stay with the Van der Spycks in the *Paviljoensgracht* near by, and remained in their house (now *Domus Spinozana*) to the end of his days. His work on the *Tractatus* involved the resumption of his earlier Hebrew studies, and it was about this time that he commenced his *Hebrew Grammar.* He did not, however, finish it, but returned to his *Ethics,* though the prospect of its publication became more and more remote. In 1672 the French invaded Holland, which was unprepared, and so suffered many disasters. The populace, fomented by the monarchists, sought a scapegoat, and murdered the brothers Jan and Cornelius de Witt. Spinoza was beside himself. He prepared a placard expressing his disgust with "the very lowest of barbarians," and was going to post it up on the scene of the crime. Fortunately Van der Spyck locked the door, and saved him from the fate of the De Witts. As it was, his *Tractatus* was denounced as an instrument "forged in hell by a renegade Jew and the devil, and issued with the knowledge of Mr. Jan de Witt." In 1673, while the French army was at Utrecht, Spinoza received an invitation to visit Prince Condé there. It was inspired by a Colonel Stoupe, who was in command of a Swiss regiment under Condé. Stoupe had been a Calvinist minister, and his service with Catholic France against Calvinist Holland evoked the severe censure of some of his countrymen. Stoupe was an unscrupulous adventurer, but was anxious to save appearances. So he conceived the idea of showing that the Dutch were really heretics, and for this purpose he wanted to use Spinoza as his cat's paw. He actually published later in that year a little book in which he denounced the Dutch for tolerating an atheist like Spinoza, and for making no attempt to answer his atheistical treatise. Spinoza only saw in the invitation a possible opportunity of initiating peace negotiations. So he consulted some people of authority, and, armed with the necessary safe-conducts, set out for Utrecht in May 1673. In the meantime Condé had been called away, and Spinoza after waiting for him several weeks in vain, returned to The Hague, where a suspicious rabble greeted him with scowls and stones, but did him no harm. Earlier in the same year another kind of invitation had reached Spinoza. It was an invitation from the Elector Palatine to the Chair of Philosophy in the University of Heidelburg. Spinoza declined the offer with many thanks. He had trouble enough with the clerics and theologians as a recluse, he would not court worse trouble by becoming a public character. So he stayed in The Hague, polishing his *Ethics* and his lenses, and generally practising the art of plain living and high thinking. The impression he made on the people about him may be gathered from the fact that one day his pious Lutheran hostess asked him whether he considered her religion the right way to salvation. Spinoza, of course, reassured her.

In 1675 the *Ethics* was finished finally, and Spinoza went to Amsterdam to see whether it might be published. But rumour had preceded him. Not only the clerics and theologians but even the "stupid Cartesians" were up in arms and brewing mischief. Spinoza, accordingly, abandoned the idea of publishing it. But manuscript copies of it were in the hands of his intimate friends. Once more he turned his attention to political problems, and began his *Political Treatise,* which he did not live to finish.

In 1675 Tschirnhaus visited Spinoza, and also brought about the resumption of the correspondence between Oldenburg and Spinoza. In 1676 Leibniz was staying in The Hague. Already in 1671 he had heard of Spinoza as an authority on optics and had sent him a copy of an optical tract. Since then he had read the *Tractatus Theologico-Politicus,* of which Spinoza then sent him a copy; and he had also learned from Tschirnhaus something about Spinoza's philosophy. He was evidently interested deeply. For, according to his own account, he visited Spinoza frequently and "conversed with him often and at great length."

The days of Spinoza were drawing to an end. The glass dust from the lenses had done its worst. He was in the last stage of consumption. About the middle of February 1677 he sent to Amsterdam for his medical friend Schuller. On Sunday, February 20, about 3 o'clock in the afternoon, Spinoza passed away in the presence of Schuller. Four days later he was buried in the New Church on the Spuy. He was only 44.

In accordance with his previous instructions his manuscripts were sent to Rieuwertsz in Amsterdam. Jelles, Meyer and Schuller prepared them secretly for the press. The *Opera Posthuma* by B. D. S. (and the Dutch version, *De Nagelate Schriften*) were published before the end of 1677. They consisted of the *Ethics,* the *Political Treatise,* the *Treatise on the Improvement of the Understanding,* the *Letters* and the *Hebrew Grammar.* The *Short Treatise* had disappeared, but two copies of a Dutch version were recovered in 1852 and an edition was published in 1862. Two short essays on *The Rainbow* (1687) and *The Calculation of Chances* were also lost for a time, but were found and published, *The Rainbow* in 1862, and both essays in 1883.

For about a century Spinoza's name was anathema. His writings were indeed studied and his ideas were borrowed to a greater extent than is commonly supposed. But people dared not mention his name with respect, much less acknowledge their indebtedness to him. In time, however, things improved. Lessing, Goethe and Coleridge did most to rehabilitate his name, and others followed suit. The monument at The Hague, the *Spinozahuis* at Rijnsburg, and the *Domus Spinozana* in The Hague bear testimony to the reverence in which the memory of Spinoza is now held throughout the civilized world.

THE PHILOSOPHY OF SPINOZA

General Account.—The pioneers of modern thought were inspired by a revulsion from the mediaeval reliance on authority, and the subordination of reason to it. The Humanists of the Renaissance attempted to vindicate the autonomy of reason as against the authority of books and institutions. This rationalist spirit affected some of the Jews of Amsterdam, and, as already remarked, brought them into conflict with established authority. It was the same spirit that brought about the crisis in the early life of Spinoza, who eventually became the prince of rationalists. He insisted that even the Scriptures must be submitted to the test of reason, and produced the most effective protest against the subordination of reason to their authority. This revolt against mere authoritarianism, however, only represented the negative side of rationalism. Important as this was, it was only preparatory to its positive aspect. The positive side of rationalism may be seen in the great classics of science in the 16th and 17th centuries—the works of Copernicus, Vesalius, Galileo, Gilbert, Kepler, Harvey, Boyle, Descartes, Huygens, Pascal, Leibniz and Newton, to mention only a round dozen of the most famous names of the period. Their discoveries were the positive results of reason, whose main function it is to trace the connections between things, to discover their laws, and to display the order which makes things intelligible. It may be said, without any

disrespect for these famous men, that the positive side of rationalism also found its fullest expression in Spinoza For he attempted a synthesis of the whole of reality. This attempt shocked some of the above-mentioned geniuses, and would have shocked the rest, had they heard of it. For none of them dreamed of the possibility of bridging the chasm between the natural and the supernatural. Spinoza conceived of the whole of reality, including the human and the divine, as an organically interconnected cosmos, in which there is nothing capricious or contingent, but everything happens in an orderly manner according to law.

Spinoza arrived at his conception partly as follows. Whatever object or event be considered, it can only be explained by reference to innumerable others which condition it. Each of these is, in turn, dependent on innumerable others. Each finite thing seems to send out innumerable tendrils and derive support from all directions Is it conceivable that reality should be composed entirely of such conditional, dependent things? Spinoza, like others, said No. There must be some self-existing, independent or absolute Being as the ground of all that is dependent. But what is the relation of this absolute Being to the world of dependent things and events? The common answer is that this absolute Being is God, an omnipotent supernatural Being who created the world out of nothing, maintains its existence, and occasionally interferes with it in miraculous ways This conception was almost universal at that time Newton subscribed to it. And Descartes made a special entry in his diary to record his belief in the three miracles, namely, the creation out of nothing, free-will, and the God-man. But Spinoza rejected the idea of an external Creator suddenly, and apparently capriciously, creating the world at one particular time rather than another, and creating it out of nothing. The solution appeared to him more perplexing than the problem, and rather unscientific in spirit as involving a break in continuity. He preferred to think of the entire system of reality as its own ground. This view was simpler; it avoided the impossible conception of creation out of nothing; and was religiously more satisfying by bringing God and man into closer relationship Instead of Nature, on the one hand, and a supernatural God, on the other, he posited one world of reality, at once Nature and God, and leaving no room for the supernatural. This so-called *Naturalism* of Spinoza is only distorted if one starts with a crude materialistic idea of Nature and supposes that Spinoza degraded God. The truth is that he raised Nature to the rank of God by conceiving Nature as the fulness of reality, as the One and All. He rejected the specious simplicity obtainable by denying the reality of Matter, or of Mind, or of God. The cosmic system comprehends them all. In fact, God and Nature become identical when each is conceived as the Perfect Self-Existent. This constitutes Spinoza's *Pantheism.*

God or Nature consists of Attributes. God, as the complete system of Attributes, is *absolutely* infinite or complete; each Attribute is only infinite of its kind. By Attribute Spinoza means an ultimate or irreducible quality or energy. He names two such Attributes, namely, Extension and Thought, but he allows for the possibility of an infinity of Attributes The Attributes do not belong to, but are identical with, Substance. Reality, moreover, is essentially dynamic, not static—to be is to be doing Thus the Attribute Extension is really the whole of material energy, and the Attribute Thought is the whole of mind-energy. All material things and events are changing modes or states of Extension; and all mental events or experiences are similarly modifications or states of Thought. Each Attribute exhausts its kind of reality, is an ultimate character, activity or "world-line" of Nature, and gives rise to its entire series of objects and events in accordance with its own laws These finite objects and events are real enough while they last, but as finite modes they change and pass; not, however, into mere nothingness, for the Attribute, of which they are states, abides. The cosmic process never stops.

Spinoza's conception of Extension and Thought, or Matter and Consciousness, as concurrent Attributes or Energies of Reality cast a new light on the problem of the relation between body and soul. Indeed, it was this problem which led him to the conception of concurrent Attributes. Under the influence of Plato and of Christianity, body and soul had come to be regarded as antagonistic to each other, and their apparently intimate relation caused much perplexity to Cartesians and others Materialists tried to explain away the soul; idealists sought to explain away the body; the Cartesian Occasionalists fell back on the miraculous intervention of God to synchronize body and soul (that is, physical and mental processes) like the wire-puller in a Punch and Judy show. Spinoza realized the *difference* between the mental and the material, but rejected the Cartesian conception of their *antagonism* So he did not hesitate to attribute to God both Extension and Thought. And man, a finite mode of God, is thus both physical and mental, and functions in both ways concurrently, even if each series of events is self-contained This solution committed Spinoza to the view that all physical beings are animated, though in very different degrees; and Spinoza accepted this view

Theory of Knowledge.—Spinoza commenced a treatise specially devoted to the problem of Knowledge But this work, the *Treatise on the Improvement of the Understanding,* was never completed In his other works epistemological discussions are intimately linked with the rest of his philosophy. Indeed, even in the *Treatise on the Improvement of the Understanding* epistemological views are almost inseparably connected with ethical and religious ones That is the consequence of his characteristic conception of "Knowledge" For Spinoza "Knowledge" is "life," not in the sense that contemplation is the highest life, but in the sense that knowledge is the means of holding together the threads of life in a systematic unity that can fill its proper place in the cosmic system. In this sense the effort after the highest knowledge becomes part of the cosmic activities by which cosmic unity is maintained, and so part of the very life of God There are two things which must be borne in mind in connection with Spinoza's conception of knowledge The first is his insistence on the *active* character of knowledge The ideas or concepts by means of which thought construes reality are not like "lifeless pictures on a panel"; they are activities by which reality is apprehended; they are part of reality, and reality is activity The second point is that Spinoza does not divorce knowing from willing. Man always acts according to his lights. If a man's endeavours appear to fall short of his knowledge, that is only because his knowledge is not really what it is held to be, but is wanting in some respect. On the one hand, reason, for Spinoza, is essentially the "practical reason" On the other hand, the highest expression of willing is experienced in that striving for consistency and harmony which is so characteristic of reason For Spinoza, then, as for Bacon and all the Renaissance thinkers, "Knowledge is power," but in a much deeper sense than Bacon intended

Spinoza's account of knowledge is particularly interesting as a clue to the way in which he gradually built up his ontology. He distinguishes three ascending grades of knowledge, namely, opinion, reason and intuition. By "opinion" Spinoza means the lowest grade of knowledge in which one assents to what one hears, perceives or imagines It is the pre-scientific stage of knowledge. Its main characteristic is that objects and events are apprehended as detached things, without any insight into their connections or laws. The second grade, or "reason," is that in which we have an insight into the connections of things and events, and their laws, it is the stage of scientific knowledge This grade of knowledge is greatly superior to the first, inasmuch as a knowledge of their connections and laws makes things more intelligible. But even this stage is imperfect because rather abstract. It reveals the course of single threads in the fabric of reality, not the whole pattern; it traces "world-lines," but affords no synoptic vision of the cosmos as a whole. It is the function of the third grade of knowledge, "intuition," to complete the scheme. In intuitive knowledge the cosmic system is grasped as a whole This highest stage is only possible for a mind that has been through the discipline of the rational stage. Unlike the mystics, Spinoza does not regard intuitive vision as a substitute for thought and entirely different from it, but rather as its highest fruit—it is "thoughtfulness matured to inspiration" The three stages of knowledge might be roughly compared with the three stages in the acquisition of the knowledge of a new language.

First come the separate letters of the alphabet; then combinations of letters into words and of words into sentences, etc., in accordance with the laws of grammar; lastly comes the stage when the significance of a whole sentence or paragraph is grasped at a glance. So it is with the great book of Nature. First comes the perception of apparently isolated facts and events; next comes the understanding of their interconnections and laws; finally comes the intuition of the structure and significance of the whole—the vision which sees all things in God, and God in all things.

Spinoza's theory of knowledge appears to make the ontological assumption that reality is an interconnected system. Spinoza himself regarded it as an ultimate intuition. And his theory of knowledge was in some ways a justification of that view. To realize this it is necessary to grasp the fundamental distinction which Spinoza draws between "opinion" and "reason," or perception and understanding. A percept or an image is, for Spinoza, something entirely different from an idea or concept. Conception or understanding is an activity which grasps interconnections, and has nothing to do with images as such. Perception and imagination, on the other hand, are concerned with images and not with connections. And the laws of these two kinds of activities are as different as are their objects. Perception, or imagination, is concerned with images and follows the laws of association; conception or understanding is concerned with connections and follows the laws of logic. Hence Spinoza's insistence that "we can not *imagine* God, but we can *conceive* Him" (*Correspondence*, p. 289). Hence also Spinoza's rejection of Baconian empiricism. From observations of particulars as such it would be impossible, according to Spinoza, to derive laws or necessary connections. The laws or general truths of science rest, in the last resort, not on their correspondence with objects of perception, but on their harmonious interconnection in a system of truths. Spinoza, accordingly, dispenses with an external criterion of truth. "The true," he maintains, "reveals itself and the false." The ultimate test of truth is more truth or more knowledge, or the coherence of all that is known. The false or untrue betrays itself by its incoherence with what is already known. In fact, Spinoza for the most part regards ideas or concepts from the point of view of their *adequacy* rather than their *truth*, in order to avoid the suggestion of a merely external correspondence such as is usually associated with the term "truth." Concepts (or "ideas" in this sense) are acts of thought by which the laws and interconnections of things and events are apprehended. They are *adequate* in so far as they really enable us to systematize a certain range of facts. In that case they are also true, for they agree with the facts. The primacy, however, is with the *adequacy* of the concept, because until we have the adequate concept we can not apprehend the facts in such a way that it can be said to agree with them, or to be *true*.

In the history of philosophy Spinoza was the first to elaborate the coherence theory of truth. In his time mathematics was the only science that could serve as a model of such a coherent system. Hence his addiction to the method of geometry. The significance of his use of this method has been misinterpreted. His sole aim was to express his philosophy in as coherent and objective a manner as possible. Two points should be noted in particular. In the first place, Spinoza did not suppose that science or philosophy can dispense with observation or experience. He fully realized the importance of experience in the very setting of the problems which science and philosophy seek to solve; and it is known from his letters that he carried out many chemical and physical experiments. All that he insisted upon was that science involves much more than mere observation, that it needs concepts not derived from experience. It was his intention to write about scientific method, and to show that Bacon's ideas about it were inadequate; but this was one of several plans which he did not live long enough to carry out. The second point is that Spinoza had no delusions about the conclusiveness of the geometrical method. He himself had expounded the philosophy of Descartes in that method, although he thoroughly disagreed with it.

Above all it is important to note that, for Spinoza, the highest knowledge ("intuitive" or "clear" knowledge) is something much fuller and richer than the abstract assertions usually associated with the term knowledge. In the *Short Treatise* (p. 69 ed. Wolf) he describes it as "feeling and enjoying the thing itself." One must try to realize his meaning by thinking of what happens when a train of thought interests a thinker so deeply as to master him completely, and he gets so absorbed in the object of his thought as to identify himself with it. If we can conjure up all this vividly and warmly, then we may realize how Spinoza came to identify the highest "knowledge" with that "intellectual love of God" in which the individual realizes himself as part of the living Universe. In this state he does not merely picture reality in an external manner, but feels its very heart throb, and feels himself as part of it. But here we are on the verge of the mystical where all but the greatest poets cease to be articulate.

Substance, Attributes, Modes.—Spinoza's ideas relating to the character and structure of reality are expressed by him in terms of *substance, attributes,* and *modes.* These terms are very old and familiar; but not in the sense in which Spinoza employs them. To understand Spinoza, it is necessary to lay aside all preconceptions about them, and follow Spinoza closely. Spinoza, as already explained, found it impossible to understand the finite, dependent, transient objects and events of experience without assuming some reality not dependent on anything else but self-existent, not produced by anything else but eternal, not restricted or limited by anything else but infinite. Such an uncaused, self-sustaining reality he called *substance.* So, *e.g.,* he could not understand the reality of material objects and physical events without assuming the reality of a self-existing, infinite and eternal physical force which expresses itself in all the movements and changes which occur, as we say, in space. This physical force he called *Extension,* and described it, at first, as a *substance,* in the sense just explained. Similarly, he could not understand the various dependent, transient mental experiences with which we are familiar without assuming the reality of a self-existing, infinite and eternal consciousness, mental force, or mind-energy, which expresses itself in all these finite experiences of perceiving and understanding, of feeling and striving. This consciousness or mind-energy he called *Thought,* and described it also, at first, as a *substance.* Each of these "substances" he regarded as infinite of its kind (that is, as exhaustive of all the events of its own kind), and as irreducible to the other, or any other, substance. But in view of the intimate way in which Extension and Thought express themselves conjointly in the life of man, Spinoza considered it necessary to conceive of Extension and Thought not as detached realities, but as constituting one organic whole or system. And in order to express this idea, he then described Extension and Thought as *Attributes,* reserving the term *Substance* for the system which they constitute between them. This change of description was not intended to deny that Extension and Thought are substances in the sense of being self-existent, etc. It was only intended to express their coherence in one system. The system of course would be more than any one attribute. For each attribute is only *infinite of its kind;* the system of all the attributes is *absolutely infinite,* that is, exhausts the whole of reality. Spinoza, accordingly, now restricted the term "substance" to the complete system, though he occasionally continued to use the phrase "substance or attribute," or described Extension as a substance. As commonly used, especially since the time of Locke, the term substance is contrasted with its attributes or qualities as their substratum or bearer. But this meaning must not be read into Spinoza. For Spinoza, Substance is not the support or bearer of the Attributes, but the system of Attributes—he actually uses the expression "Substance or the Attributes." If there is any difference at all between "Substance" and "the Attributes," as Spinoza uses these terms, it is only the difference between the Attributes conceived as an organic system and the Attributes conceived (but not by Spinoza) as a mere sum of detached forces. Something is still necessary to complete the account of Spinoza's conception of Substance. We have so far only considered the two Attributes, namely, Extension and

Thought. Spinoza, however, realized that there may be other Attributes, unknown to man If so, they are all part of the one Substance or cosmic system And using the term "infinite" in the sense of "complete" or "exhaustive," he ascribed to Substance an infinity of Attributes, that is, all the Attributes there are, whether known to man or not.

Now reality, for Spinoza, is activity. Substance is incessantly active, each Attribute exercising its kind of energy in all possible ways. Thus the various objects and events of the material world come into being as modes (modifications or states) of the attribute Extension; and the various minds and mental experiences come into being as modes of the attribute Thought (or Consciousness) These modes are not external creations of the Attributes, but immanent results—they are not "thrown off" by the Attributes, but are states (or modifications) of them, as air-waves are states of the air. Each Attribute, however, expresses itself in its finite modes not immediately (or directly) but mediately (or indirectly), at least in the sense to be explained now Galilean physics tended to regard the whole world of physical phenomena as the result of differences of motion or momentum. And, though erroneously conceived, the Cartesian conception of a constant quantity of motion in the world led Spinoza to conceive of all physical phenomena as so many varying expressions of that store of motion (or motion and rest) Spinoza might, of course, have identified Extension with energy of motion But, with his usual caution, he appears to have suspected that motion may be only one of several types of physical energy. So he described motion simply as a mode of Extension, but as an *infinite* mode (because complete or exhaustive of all finite modes of motion) and as an *immediate* mode (as a direct expression of Extension) Again, the physical world (or "the face of the world as a whole," as Spinoza calls it) retains a certain sameness in spite of the innumerable changes in detail that are going on Accordingly, Spinoza described also the physical world as a whole as an *infinite* mode of Extension ("infinite" because exhaustive of all facts and events that can be reduced to motion), but as a *mediate* (or indirect) mode, because he regarded it as the outcome of the conservation of motion (itself a mode, though an *immediate* mode). The physical things and events of ordinary experience are *finite* modes In essence each of them is part of the Attribute Extension, which is active in each of them But the finiteness of each of them is due to the fact that it is restrained or hedged in, so to say, by other finite modes This limitation or determination is negation in the sense that each finite mode is *not* the whole attribute Extension, it is not the other finite modes But each mode is positively real and ultimate as part of the Attribute

In the same kind of way the Attribute Thought exercises its activity in various mental processes, and in such systems of mental process as are called minds or souls But in this case, as in the case of Extension, Spinoza conceives of the finite modes of Thought as mediated by infinite modes The immediate infinite mode of Thought he describes as "the idea of God"; the mediate infinite mode he calls "the infinite idea" or "the idea of all things." The other Attributes (if any) must be conceived in an analogous manner And the whole Universe or Substance is conceived as one dynamic system of which the various Attributes are the several world-lines along which it expresses itself in all the infinite variety of events

Having regard to the persistent misinterpretation of Spinozism it may be as well to emphasize the dynamic character of reality as Spinoza conceived it The cosmic system is certainly a logical or rational system, according to Spinoza, for Thought is a constitutive part of it; but it is not *merely* a logical system—it is dynamic as well as logical His frequent use of geometrical illustrations affords no evidence at all in support of a purely logico-mathematical interpretation of his philosophy; for Spinoza regarded geometrical figures, not in a Platonic or static manner, but as things traced out by moving particles or lines, etc, that is, dynamically.

Emergence.—A few words may be added here to indicate the merits of Spinoza's conception of the Universe in relation to the doctrine of emergent evolution as maintained by C Lloyd Morgan and S Alexander. (*See* EMERGENCE and PHILOSOPHY, HISTORY OF) If reality is considered from the point of view of the finite modes (or *Natura naturata,* in Spinoza's terminology) instead of from that of Substance or the Attributes (or *Natura naturans*), then beginning with the simplest kinds of modes and passing on to more and more complex combinations of them, each such combination will always be something more than the mere sum of its components To this extent something new emerges at every stage where a system is formed out of simple constituents At a certain stage we reach the various infinite modes, then the several Attributes, and finally God For Spinoza, however, God or the Attributes and the Infinite Modes are eternal, so that the process of evolution can only concern the world of finite modes This kind of emergent evolution Spinoza can be said to recognize when he identifies moral progress with ever widening synthesis—"the more perfection (*i e* , reality) anything has, the more does it participate also in Deity" (*Correspondence*, p 151). But Spinoza's conception has an advantage over the new conception of "emergence" (including the emergence of Deity) For the new doctrine involves the conception of the emergence of something out of nothing, inasmuch as the "emergent" is not contained in the sum of its conditions, but is something new For Spinoza, on the other hand, the fulness of reality in all its essentials is always there, and the emergence of higher modes with the increasing synthesis or "holism" (*q v*) of lower modes does not involve a miraculous emergence of something out of nothing, but merely a rearrangement of what is already real

Moral Philosophy.—For Spinoza, reality means activity, and the reality of anything expresses itself in a tendency to self-preservation—to exist is to persist In the lowest kinds of things, in so-called inanimate matter, this tendency shows itself as inertia, in living organisms, it shows itself as a "will to live" Regarded physiologically this effort is called *appetite;* when we are conscious of it, it is called *desire* The moral categories, good and evil, are intimately connected with desire, though not in the way commonly supposed Man does not desire a thing because he thinks it is good, or shun it because he considers it bad, rather he considers anything good if he desires it, and regards it as bad if he has an aversion for it Now whatever is felt to heighten vital activity gives pleasure, whatever is felt to lower such activity causes pain Pleasure coupled with a consciousness of its external cause is called love, and pain coupled with a consciousness of its external cause is called hate—"love" and "hate" being used in the wide sense of "like" and "dislike" All human feelings are derived from pleasure, pain and desire Their great variety is due to the differences in the kinds of external objects which give rise to them, and to the differences in the inner conditions of the individual experiencing them Spinoza gives a detailed analysis of the whole gamut of human feelings, and his account is one of the classics of psychology For the present purpose the most important distinction is that between "active" feelings and "passive" feelings (or "passions"). Man, according to Spinoza, is active or free in so far as any experience is the outcome solely of his own nature, he is passive, or a bondsman, in so far as any experience is due to other causes besides his own nature The active feelings are all of them forms of self-realization, of heightened activity, of strength of mind, and are therefore always pleasurable It is the passive feelings (or "passions") which are responsible for all the ills of life, for they are induced largely by things outside us and frequently cause that lowered vitality which means pain Spinoza next links up his ethics with his theory of knowledge, and correlates the moral progress of man with his intellectual progress At the lowest stage of knowledge, that of "opinion," man is under the dominant influence of things outside himself, and so is in the bondage of the passions At the next stage, the stage of "reason," the characteristic feature of the human mind, its intelligence, asserts itself, and helps to emancipate him from his bondage to the senses and external allurements The insight gained into the nature of the passions helps to free man from their domination A better understanding of his own place in the cosmic system and of the place of all the objects of his likes and dislikes, and his insight into the neces-

sity which rules all things, tend to cure him of his resentments, regrets and disappointments. He grows reconciled to things, and wins peace of mind. In this way reason teaches acquiescence in the universal order, and elevates the mind above the turmoil of passion. At the highest stage of knowledge, that of "intuitive knowledge," the mind apprehends all things as expressions of the eternal cosmos. It sees all things in God, and God in all things. It feels itself as part of the eternal order, identifying its thoughts with cosmic thought and its interests with cosmic interests. Thereby it becomes eternal as one of the eternal ideas in which the Attribute Thought expresses itself, and attains to that "blessedness" which "is not the reward of virtue, but virtue itself," that is, the perfect joy which characterises perfect self-activity. This is not an easy or a common achievement. "But," says Spinoza, "everything excellent is as difficult as it is rare."

Two things at least must be added to prevent a misunderstanding of this slight sketch of Spinoza's ethics. The first is that he did not teach asceticism. Circumstances compelled him to be extremely frugal and live on a few pence a day; but he affected no contempt for the joys of life. On the contrary, he urged that "it is the part of a wise man to use the world and delight himself in it as best he may, though not to satiety, for that is no delight." The second point is that Spinoza, though compelled by circumstances to live the life of a recluse more or less, laid great stress on the social character of the moral life. "Men," he says, "will find that their needs are best satisfied by mutual help, and that only by uniting their strength can they escape the dangers that beset them everywhere." He insists further that the good pursued by reasonable men is a good that may be enjoyed by all, and that the virtuous man wants no special privileges, but desires also for his fellow men whatever he desires for himself. The third point is that Spinoza's contention that the conception of goodness, like that of purpose, is inapplicable to the cosmic system as a whole does not mean that he denied the validity of the distinction between good and evil in the realm of human conduct. The notions "good" and "evil" involve the conception of an ideal that is desired but not yet realized, and the realization of which is helped by some things, hindered by others. Now the cosmic system, or God, is completely real or perfect, and therefore "beyond good and evil." But with finite modes like men it is quite different. Much can be done that really heightens or lowers human life. Whatever enriches it really is good; whatever impoverishes it really is bad, even if its badness is something negative, a defect, rather than something positive.

Political Philosophy.—Spinoza agreed with Hobbes that if each man had to fend for himself, with nothing but his own right arm to rely upon, then the life of man would be "nasty, brutish and short." The truly human life is only possible in an organized community, that is, a state or commonwealth. The state ensures security of life, limb and property; it brings within reach of every individual many necessaries of life which he could not produce by himself; and it sets free sufficient time and energy for the higher development of human powers. Now the existence of a state depends upon a kind of implicit agreement on the part of its members or citizens to obey the sovereign authority which governs it. In a state no one can be allowed to do just as he pleases. Every citizen is obliged to obey its laws; and he is not free even to interpret the laws in a special manner. This looks at first like a loss of freedom on the part of the individuals, and the establishment of an absolute power over them. Yet that is not really so. In the first place, without the advantages of an organized state the average individual would be so subject to dangers and hardships of all kinds and to his own passions that he could not be called free in any real sense of the term, least of all in the sense in which Spinoza used it. Man needs the state not only to save him from others but also from his own lower impulses and to enable him to live a life of reason, which alone is truly human. In the second place, state sovereignty is never really absolute. It is true that almost any kind of government is better than none, so that it is worth while bearing much that is irksome rather than disturb the peace. But a reasonably wise government will even in its own interests endeavour to secure the good will and co-operation of its citizens by refraining from unreasonable measures, and will permit or even encourage its citizens to advocate reforms, provided they employ peaceable means. In this way the state really rests, in the last resort, on the united will of the citizens, on what Rousseau, who read Spinoza, subsequently called the "general will." Spinoza sometimes writes as if he upheld absolute sovereignty. But that is due mainly to his determined opposition to every kind of ecclesiastical control over the state. Though he is prepared to support what may be called a state religion, as a kind of spiritual cement, yet his account of this religion is such as to make it acceptable to the adherents of any one of the historic creeds, to deists, pantheists and all others, provided they are not fanatical believers or unbelievers. It is really in the interests of freedom of thought and speech that Spinoza would entrust the civil government with something approaching absolute sovereignty in order to effectively resist the tyranny of the militant churches.

One of the most striking features in Spinoza's political theory is his basic principle that Right is Might. This principle he applied systematically to the whole problem of government, and seemed rather pleased with his achievement, inasmuch as it enabled him to treat political theory in a scientific spirit, as if he were dealing with applied mathematics. The identification or correlation of right with power has caused much misunderstanding. People supposed that Spinoza reduced justice to brute force. But Spinoza was very far from approving *Realpolitik*. In the philosophy of Spinoza the term "power" (as should be clear from the above account of his moral philosophy) means a great deal more than physical force. In a passage near the end of his *Political Treatise* he states explicitly that "human power chiefly consists in strength of mind and intellect"—it consists in fact, of all the human capacities and aptitudes, especially the highest of them. Conceived correctly, Spinoza's whole philosophy leaves ample scope for ideal motives in the life of the individual and of the community.

Spinoza discusses the principal kinds of states, or the main types of government, namely, Monarchy, Aristocracy and Democracy. Each has its own peculiarities and needs special safeguards, if it is to realize the primary function of a state. Monarchy may degenerate into Tyranny unless it is subjected to various constitutional checks which will prevent any attempt at autocracy. Similarly, Aristocracy may degenerate into Oligarchy, and needs analogous checks. On the whole, Spinoza favours Democracy, by which he meant any kind of representative government. In the case of Democracy the community and the government are more nearly identical than in the case of Monarchy or Aristocracy; consequently a democracy is least likely to experience frequent collisions between the people and the government, and so is best adapted to secure and maintain that peace which it is the business of the state to secure.

Bible Criticism.—Spinoza was not only the real father of modern metaphysics and moral and political philosophy, but also of the so-called higher criticism of the Bible. This part of his work was incidental to his plea for freedom of thought and speech. His *Tractatus Theologico-Politicus* undertook to show that the Scriptures properly understood gave no authority for the militant intolerance of the clergy who sought to stifle all dissent by the use of force. To achieve his object, Spinoza had to show what is meant by a proper understanding of the Bible. And this gave him occasion to apply criticism to the Bible. To appreciate his services in this connection it must be remembered that his age was remarkably lacking in historical sense, especially in matters relating to religion. Saintly contemporaries like John Bunyan and Manasseh ben Israel made the most fantastic use of Scripture texts; while militant clerics, relying on the ignorant bibliolatry of the masses, misapplied Bible texts to gain their ends. Spinoza, who permitted no supernatural rival to Nature and no rival authority to the civil government of the state, rejected also all claims that Biblical literature should be treated in a manner entirely different from that in which any other document is treated that claims to be historical. His contention that the Bible "is in parts imperfect, corrupt, erroneous, and inconsistent with itself, and that we possess but fragments of it" roused a

great storm at the time, and was mainly responsible for his evil repute for a century at least. Nevertheless, the intelligent world has gradually come round to his views, and has learned to agree with him that the real "word of God," or true religion, is not something written in books but "inscribed on the heart and mind of man." And many ministers of religion now praise Spinoza's services in the correct interpretation of Scripture as a document of first rate importance in the progressive development of human thought and conduct.

BIBLIOGRAPHY.—*Biographies:* (M. Lucas) *The Oldest Biography of Spinoza*, edited, translated and annotated by A Wolf (1927), A Wolf, *Spinoza; His Life and Treatise on God and Man* (1910); J. Freudenthal, *Das Leben Spinozas* (1904, 1927), and *Die Lebensgeschichte Spinozas in Quellenschriften*, etc (1899); E Dunin-Borkowski, *Der Junge de Spinoza* (1910). *Works:* The best edition is *Spinoza Opera* (4 vols.) edited by C. Gebhardt (Heidelberg, 1926). *Translations:* An English translation of the complete works of Spinoza (with introductions and commentaries) by A. Wolf is in course of preparation, the volume containing the complete *Correspondence of Spinoza* was published in 1928. Of other English translations the following are the most important. *Spinoza's Chief Works* translated by R. H Elwes (2 vols, 1883–84, etc.), *Ethics* translated by Hale White and A. H. Stirling (1899); *A Short Treatise on God, Man and his Well-being* translated by A. Wolf (1910) The best French translations are those by E Saisset (3 vols, 1861) and Ch Appuhn (4 vols, 1904, etc) The best German translations are those by B Auerbach (2 vols, 1871), and by O. Baensch, C. Gebhardt and others (3 vols, 1914–22). *Books on Spinoza's Philosophy*, etc The following are the most important F. Pollock, *Spinoza, His Life and Philosophy* (1880, 1899, 1911), J Martineau, *A Study of Spinoza* (1882, 1883, 1895); J Caird, *Spinoza* (1888, 1901), H. H Joachim, *A Study of the Ethics of Spinoza* (1901); R. A. Duff, *Spinoza's Ethical and Political Philosophy* (1903); L. Roth, *Spinoza, Descartes, and Maimonides* (1924), J. A Gunn, *Benedict Spinoza* (1925) contains a bibliography, R McKeon, *The Philosophy of Spinoza* (1928); L. Roth, *Spinoza* (1929) Of *German Books* the most important are D Camerer, *Die Lehre Spinozas* (1877, 1914), K Fischer, *Spinoza* (5th ed, 1909); J Freudenthal, *Spinoza, Leben und Lehre* (1928) Of *French Books* the most important are L Brunschvicg, *Spinoza et ses Contemporains* (1923); V Delbos, *Le Problème moral dans la Philosophie de Spinoza* (1893) and *Le Spinozisme* (1916) Of *Multilingual Books* the following two series (both edited by C Gebhardt) are the most important *Chronicon Spinozanum* (since 1921) and *Bibliotheca Spinozana* (since 1922).

(A. Wo)

SPINY SQUIRREL, a group of African ground squirrels, characterized by the spiny nature of the fur They form the genera *Xerus, Euxerus, Atlantoxerus* and *Geosciurus*, being characterized by the small size or absence of the ears, and the long, nearly straight, claws Typical spiny squirrels live in clefts or holes of rocks, or in burrows (*See* RODENTIA)

SPION KOP, a mountain in Natal on the north side of the Tugela river, and 24 m W S W. of Ladysmith It is celebrated as the scene of a battle (Jan. 24, 1900) in the Transvaal War, in which the British forces under Sir Redvers Buller were defeated by the Boers (*see* TRANSVAAL and LADYSMITH)

SPIRAEA, in botany, a genus of shrubs of the rose family (Rosaceae, *q v.*), comprising about 75 species, natives of the northern hemisphere They are mostly slender shrubs, 2 to 8 ft high, usually with simple leaves and small white, pink or reddish flowers arranged in dense showy clusters. *S salicifolia* (meadow-sweet) occurs in England and Scotland *S. latifolia* (American meadow-sweet), *S. alba* (white meadow-sweet) and S *tomentosa* (hardhack, *q.v*) are representative species of eastern North America *S. Douglasii* (western meadow-sweet) occurs on the Pacific coast. Among the best-known cultivated forms are *S prunifolia* (bridal-wreath) and the popular hybrid *S. Van Houttei.*

SPIRAL: *see* CURVES

SPIRE, in architecture, a steep, pyramidal form, crowning a tower. The origin of the form was the simple, four-sided, pyramidal roof frequently erected over Romanesque towers, as in many crude 11th century examples in Normandy, some of the Italian campaniles of the 11th and 12th centuries, and many German Romanesque towers, mostly of the 12th century This form is abrupt and stunted and may easily be ungraceful, and various experimental attempts were made to soften the line. Thus the late 11th century tower at Le Puy en Velay has the successive stages of the tower receding and broken up by projecting bays on the sides. Furthermore, the pyramidal roof itself is decorated with corner finials and small, round-headed dormers. In Germany the form was varied by ending each face of the square tower in a gable, the plane determined by adjacent gable slopes establishing the slope of the pyramid, as in the square tower of the abbey church of Laach (*c.* 1156). The pleasanter effect of the octagonal spires over octagonal towers, like another of the towers at Laach, or the older of the two towers at Mainz (late 12th century), led to attempts to combine an octagonal spire with a square tower This was accomplished in various ways, one of the simplest being the so-called broach spire, in which small, triangular planes of a less steep pitch than that of the spire proper occur at the bottom of the corner spire faces, with their lower points coinciding with the corners of the towers, as seen in the 12th century church of S. Columba at Cologne

A more developed form of broach spire lies in the substitution of a small pyramid at the bottom of the corner faces, instead of the triangular plane. This is a type which became common in English Gothic spires. It may be described geometrically as the intersection of a four-sided pyramid of low slope by an eight-sided pyramid of steep slope, as in the 14th century spire of St. Mary's at Stamford A more elaborate method of softening the junction between square and octagon was to carry the corner faces down unbroken to the top of the tower and fill the triangular corners thus left with decorative finials. An early example is the crossing tower of the church of S. Ours, at Loches, France (12th century)

In the south-west tower of Chartres cathedral (end of the 12th century) a further advance is made in connecting tower and spire, by adding high, gabled dormers on the faces of the spire, over the centres of the tower faces, as well as richly developing the corner pinnacles In the spire at Senlis cathedral (13th century) a vertical, octagonal stage, or lantern, is placed between the square tower and the octagonal spire. The corners of the square tower are occupied by pinnacles and eight slim dormers surround the spire base The edges of the Chartres and Senlis spires are decorated with projecting roll mouldings, and those at Senlis are further enriched by crockets which form an admirable fretting of the silhouette It is probable that similar crocketed spires were almost universally intended over the great towers of most of the French cathedrals The towers at Laon, for instance, were once so crowned and spires at Reims and Amiens were begun

Gothic Climax.—It was in Normandy, England and Germany that Gothic spire design reached its climax Particularly famous are the spires of S. Sauveur at Caen (14th century); S Pierre at Caen (1308) and the magnificent group of spires at Coutances cathedral (13th century), in which the spire dormers and the corner pinnacles are treated with the utmost richness and the sense of height and slimness emphasized in every possible manner The customary lavishness of the French Flamboyant style is magnificently illustrated in its pierced and intricately traceried spires The two most remarkable examples are the northern spire of Chartres cathedral (1506–13), by Jehan Texier, and the so-called Tour de Beurre (*c* 1520) of the cathedral at Rouen

Spires of a simple type crown many of the Italian campaniles, and during the 13th, 14th and 15th centuries, spires and lanterns were frequently added to earlier towers In neither Italy nor Spain, however, was the highly developed spire a native form, and Italian spires were simple, slate, tile or metal covered, pyramidal or conical roofs of timber Burgos cathedral is unique in Spain in possessing two western spires of intricate, open-work masonry, which date from the 15th century. These, however, are known to have been designed by a German architect.

German luxuriance, which had already appeared in the numerous varieties of timber spires used on the Rhenish Romanesque churches, found equally congenial expression in the stone spires of the Gothic period The early, simple type is seen in the solid spires of S. Elizabeth at Marburg (not completed until the middle of the 14th century but probably from a 13th century design) The cathedral at Freiburg has a spire (1270–88) which is of a new and infinitely richer type. The low, square tower carries a high, octagonal lantern, each side of which is capped by a slim gable and filled with delicate tracery, the corners of the square being filled with rich, triangular pinnacles, one of which is con-

tinued up as an open, spiral staircase, giving access to the upper portion. The spire rises above the lantern, a mere cage of open-work tracery, with crocketted edges, amazingly light and delicate in effect. Somewhat similar, although even more intricate in their pierced stone-work are the western spires of Regensburg cathedral (late 15th century), by Roritzer. These open-work spires became the rule in Germany, as illustrated in the intricate cage of Strasbourg cathedral (spire, 1435); the west towers of Cologne cathedral, built in the 19th century from mediaeval drawings; the over-complicated lace-work of the cathedral at Vienna (1433) and the spire at Ulm, over 500 ft. high, built in the last years of the 19th century, from 15th century drawings.

The spire of Oxford cathedral (1220) is a perfect example of the Early English spire type; it is octagonal, has a marked entasis or convex curve, and is decorated with dormers on each face and corner pinnacles. The great spire of Salisbury cathedral (1250), 406 ft. high, shows the tremendous aesthetic advantage of the greater steepness there present, which became the rule in the later English spires. During the Decorated period it became customary to finish the top of the tower with a parapet, either battlemented or of pierced tracery, and to set back the base of the spire behind the face of the wall. With this change the use of broaches disappeared and tall, corner pinnacles, sometimes supported on corner buttresses, filled the tower corners. An early example of the parapeted tower with a spire, in which broaches remain and the corner pinnacles are raised up to the top of the broach, is that of Ashbourne church, Derbyshire (14th century). Among the loveliest of Decorated spires are the two western spires of Lichfield cathedral, with heavy but effective, corner pinnacles. The highly developed type of spire with corner pinnacles and a parapet below can be seen in St. Peter's, Kettering, and Sts. Peter and Paul, Oundle (both in Northamptonshire), both of the Perpendicular period. In other examples a little flying buttress connects the corner pinnacles with the face of the spire, as in the exquisite Perpendicular spire of Louth church, Lincolnshire. Many Perpendicular spires are often ornamented with crockets up the angles.

Renaissance.—The spire was a form never thoroughly absorbed by the Renaissance, which preferred domed lanterns crowning towers. Nevertheless, during the 17th century in Germany, most effective, fantastic, spire-like forms were developed. These, based partly on Italian Baroque prototypes, usually had profiles of broken concave and convex lines, crowned at the top with a sort of onion dome, the whole rising to a considerable height, and, in imaginative quality, far surpassing any of the Italian examples. It is such fantastic spires crowning the simple towers of village churches, which give much of their character to the little towns of south Germany and Austria. At the same time, in England, the spire idea was receiving a much simpler and more straightforward, and equally effective, Renaissance expression, through the efforts of Sir Christopher Wren and his followers, particularly in the churches built after the Great Fire of London in 1666, such as St. Martin's, Ludgate hill, St. Mary-le-Bow and St. Bride's, Fleet street, all by Wren. St. Mary-le-Strand (early 18th century) and St. Martin's-in-the-Fields (1721–1726) both by James Gibbs, which simplified and refined upon their Wren prototypes, are very successful.

Even more effective are many American colonial spires, which, although originally based upon the work of Wren and Gibbs, achieved a fresh beauty through still further simplification. Particularly noteworthy is the type in which a small, octagonal, arcaded lantern crowns a simple, square tower and carries, usually above an attic, a simple, slim, white spire, as in the Old South Meeting House, Boston (1729) and the extremely delicate, white, wooden steeple of the church at Farmington, Conn. (*c.* middle 18th century). Such steeples as that of S. Paul's chapel, New York (*c.* 1767), Christ church, Philadelphia (1754) and S. Michael's, Charleston, S.C. (1742, occasionally attributed to James Gibbs himself), although more monumental in treatment and more English in effect, still retain the characteristic American delicacy. This trend toward the more slender and attenuated proportions reached its climax in the exquisitely light spire of Park street church, Boston (1819), by Peter Banner. (For bibliography *see* GOTHIC ARCHITECTURE.) (T. F. H.)

SPIRE LIGHT, the term given to the windows in a spire which are found in all periods of English Gothic architecture and are an important feature in French spires. They are not glazed, and, if of large size, sometimes have transoms to strengthen the mullions.

SPIRES: *see* SPEYER.

SPIRITS. In the chemical sense the word is sometimes applied to acids having a volatile character, as "spirits of salts" or hydrochloric acid. The name is generally restricted to distilled liquors. The *Spiritus Rectificatus* of the British Pharmacopoeia is a mixture of ethyl alcohol and water in the volume proportions of 90 to 10. There are also four standard diluted alcohols recognized by the same authority containing respectively 70, 60, 45 and 20% of ethyl alcohol by volume. The spirits of the British Pharmacopoeia (*e.g.*, Sp. aetheris nitrosi; sp. chloroformi; sp. camphorae) are solutions of various substances obtained either by distilling them with, or dissolving them in, rectified spirit.

According to the British Spirits Act of 1880 "spirits" means spirits of any description and includes all liquors mixed with spirits, and all mixtures, compounds, or preparations made with spirits. The same enactment defines "plain spirits" as "British spirits (except low wines and feints) which have not had any flavour communicated thereto or ingredient or material mixed therewith," and "spirits of wine" as "rectified spirits of the strength of not less than 43 degrees above proof," *i.e.*, 75·36% of alcohol by weight or 81·59% by volume.

In its popular use "spirits" is generally understood to mean alcoholic beverages, *e.g.*, brandy, rum, whisky, distilled from liquids which have undergone a process of fermentation.

Proof Spirit.—The British standard spirit is "proof spirit," which was defined by the Spirits Act of 1816 as "that which at the temperature of 51° F weighs exactly $\frac{12}{13}$ of an equal measure of distilled water." The temperature of the water was not defined, but there is some documentary evidence indicating that it was intended to be 51° F. A mixture of water and ethyl alcohol complying with this condition has, at 60° F, a specific gravity of 0·91976 and contains 49·28% of alcohol by weight and 51·10% by volume. Mixtures in other proportions are said to be "over proof" or "under proof," the expression of strength being based upon the number of volumes of proof spirit which could be obtained from one hundred volumes of the mixture at 50° F. Thus a strong spirit 100 volumes of which would, on the addition of water, give 166 volumes of proof spirit, is described as having a strength of 166% proof, or 66 degrees over proof, whilst one which contains, in 100 volumes, sufficient alcohol to give 45 volumes of proof spirit has a strength of 45% proof, or 55 degrees under proof. The proof gallon equivalent of a mixture, the strength and volume of which have been determined, can be ascertained by multiplying the volume in gallons by the strength and dividing by 100. Absolute alcohol has a strength of 75·35 degrees over proof.

The instrument in general use for determination of spirituous strength in Great Britain and the British Dominions is the Sikes hydrometer, legalized by 56 Geo. III. c. 40 in 1816. It is usually made of gilded brass and consists of a hollow sphere provided at one pole with a graduated rectangular stem of uniform section. At the other pole is a stem terminating in an oval counterpoise intended to give stability to the instrument when floating and to serve as a means of attachment for additional poises. The graduations of the upper stem consist of divisions marked respectively 0 to 10 from top to bottom, each division having five subdivisions. There are nine additional poises marked respectively 10, 20, etc. up to 90, the stem indication being added to the number of the requisite poise for the purpose of reading. The tables used with the instrument correlate proof strengths with the hydrometer readings. The original tables were compiled by Sikes and were legalized with the instrument. New tables were substituted by the Finance (No. 2) Act of 1915. They show the strength appropriate to each indication of the hydrometer at every degree Fahrenheit from 30 to 100, the range of strength at 60° F being from water at indication 100 to 66·7

overproof at indication 0·0. For higher strengths two additional instruments have been introduced, viz, Sikes' "A" hydrometer, which at 60° F records strengths from 66 7 o p to 73 5 o p and Sikes' "B" hydrometer which renders possible the determination of the highest strengths at temperatures up to 85° F.

As already stated, the proof strengths are based upon percentages by volume at 50° F but, owing to the difference in the coefficient of expansion of water and alcohol, the volume proportions at other temperatures differ from those at 50° F Sikes' system does not take account of this and the strength recorded is that of the mixture when at the basic temperature Although this may be open to some objection it is of advantage to the revenue and to the trader as it renders possible the identification of a spirit and the recording of the same strength regardless of the temperature when tested

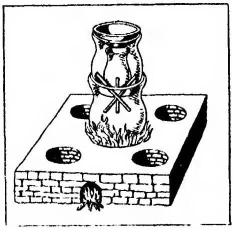


FIG 1 —ANCIENT FORM OF STILL, USED IN TIBET

This method of assessment of alcoholic strength depends upon the difference in the respective specific gravities of alcohol and water, and the determination of the specific gravities appropriate to mixtures of these two substances is therefore of great importance At the request of the British Government the Royal Society undertook an investigation of this problem towards the close of the 18th century and entrusted the work to Sir Charles Blagden, the secretary, and George Gilpin, clerk to the Society The results of their experiments were published in the Philosophical Transactions 1790–94 and were of such great merit that they not only formed the basis of Sikes's values but are incorporated in many of the official tables of the present day, including those legalized in Britain in 1915 Tralles in 1911 conducted a similar investigation for the Prussian Government, whilst Gay Lussac (Paris, 1824), McCulloch (Washington, 1848), Baumhauer (Amsterdam, 1860), Mendeleeff (St Petersburg, 1865), the Kaiserliche Normal Eichungs Kommission (Berlin, 1889), and Bureau of Standards (Washington, 1913 and 1929) were also responsible for considerable work under the auspices of their respective Governments In the United States of America a "proof" standard is adopted, Section 3249 of the Revised Statutes provides that "proof spirit shall be held to be that alcoholic liquor which contains one-half its volume of alcohol of a specific gravity of 0 7939 at sixty degrees Fahrenheit" In Holland also a "proof" spirit forms the basis of the revenue charge, the standard being 50% by volume of anhydrous alcohol at 15° C

Historical.—The origin of the practice of distillation is lost in antiquity Olympiodorus, in a commentary on the second book of Aristotle's *Meteors*, states that sailors boiled the sea water and suspended large sponges from the mouth of a brazen vessel in order to imbibe the "sweet water" which is evaporated According to Fairley the Chinese distilled liquor, *Sautchoo* was known long before the Christian era and *arrack* was made in India as early as 800 B C According to this and other evidence accumulated from ancient literature there is little doubt that spirits were manufactured in the East many centuries before Christ It appears to be well established that about the end of the fourth century A D Zosimus described an apparatus for distilling, whilst Geber, who is said to have lived in the seventh century of the Christian era, gave an account of the process, which he described as "the raising of aqueous vapour in any vessel in which it is placed" According to Fairley (*The Analyst*, 1905) the earliest known reference to the preparation of a spirituous liquor by distillation in Great Britain is contained in the "Mead Song" by the Welsh bard Taliesin in the sixth century Fairley also points out that distillation from fermented grain liquor was practised in Ireland before the distillation of wine was introduced. St Patrick is credited by an old Irish legend with having first taught the Irish the art of distillation, it is certain that at the time of the first English invasion of Ireland (1170–72) the manufacture of a spirit distilled from grain (*i e*, whisky) was known It is probable also that the distillation of spirit in Scotland dates back to the same early period Towards the end of the century much home-produced spirit was obtainable in England from apothecaries and vintners. The dissolution of the monasteries under Henry VIII resulted in many of the disestablished monks setting up in business as distillers, brewers and vinegar makers, and during the Tudor period the distilling trade became firmly established The production of a spirit from wine (*i e*, brandy) appears to have been known in the ninth century but according to Morewood the first attempt at the distillation of wine in France is attributed to Arnaldus de Villa Nova in the 13th century. As a manufacturing industry the distillation of brandy in France began in the 14th century.

Official Control of Spirit Trade.—For centuries the preparation and sale of spirits in Great Britain has been under Government control During the reign of Elizabeth a royal patent was issued to Candishe and later to Richard Drake to survey "the corrupt sorts of aqua vitae, aqua composita and usquebagh" In 1643 excise duties on spirits were regularly imposed, the tax being collected by the newly constituted excise department By an act passed in 1657, the excise authorities were given wide powers of control over spirit manufacturers and dealers Under the Spirits Act of 1880 the conditions imposed upon the trade are exceedingly strict. A distiller must give notice to the authorities of the erection of any new plant or apparatus and must obtain their approval He must notify the excise officer of the time of many of his manufacturing operations He may not upon his distillery or any premises communicating therewith brew beer, refine sugar, deal in wine or make sweets, vinegar, cider or perry He must keep records in the form prescribed by the Commissioners of Customs and Excise of the quantities of materials used in each operation and of the results of observations to be made at various stages

There are three methods of assessing duty and whichever gives the highest amount is adopted The first is the "attenuation charge." This consists of levying the charge due on one gal of proof spirit for every 100 gal of worts collected and for every five degrees of attenuation observed, the latter being calculated by taking the difference between the highest specific gravity of the worts and the lowest gravity of the wash after complete fermentation. The second method is the "low wines" charge calculated upon the bulk quantity at proof strength of the low wines produced by the distillation of the wash The third is the "feints and spirits" charge, assessed upon the number of proof gallons of feints and spirits produced by the final operations

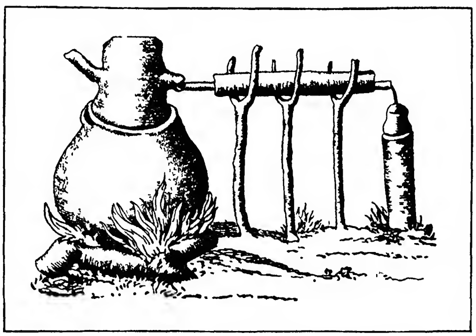

FIG 2 —STILL OF ANCIENT TYPE AS USED IN TAHITI

Production and Consumption.—The development of official control has been coincident with a steady increase in the rate of duty on spirit and the total contribution to the national revenue from this source showed a corresponding growth until other influences affected the consumption of alcoholic beverages Thus in 1643 the rate of customs or excise duty on "strong waters or aqua vitae" was 8d per gallon The customs duties on spirits

*Figures for United Kingdom: those for later years refer to Great Britain and Northern Ireland only.
†This table does not include spirits delivered for methylation, use in arts and manufacture, or in fortified wines.

imported into Great Britain and Northern Ireland per proof gallon are, in 1929, as follows: Brandy and rum, £3.15.4; Imitation rum, Geneva, £3.15.5; Sweetened spirits, *e.g.*, liqueurs, cordials, etc., £3.15.11; Unsweetened spirits, *e.g.*, liqueurs, cordials, etc., £3.15.5.

There are many modifications of these rates, preferential treatment being accorded for instance, to goods of Empire origin, while a reduction is also allowed for spirits which can be proved to be of a certain maturity. The corresponding maximum excise duty is £3.14.0 per proof gallon.

The total revenue derived from spirits in recent years has been as follows:

Spirit Duties (Net Receipts)

Year	Customs (Imported)				Excise (home made)	Total
	Rum	Brandy	Other sorts	Total		
	£	£	£	£	£	£
1923-24	4,839,167	2,646,265	1,407,222	8,892,654	45,144,092	54,036,746
1924-25	4,189,670	2,475,646	1,563,616	8,228,932	42,824,674	51,053,606
1925-26	3,995,727	2,411,630	1,530,582	7,937,939	41,989,706	49,927,645
1926-27	3,110,118	2,103,573	1,280,588	6,494,279	37,058,506	43,552,785

The production of spirit in the United Kingdom amounted in 1907 to roughly 50,000,000 proof gallons. In the decade 1880–90 the quantity annually distilled remained practically stationary at about 40,000,000 gal., but during the years 1890–1900 there was a rapid increase, the maximum being attained in 1898 when nearly 64,000,000 gal. were produced. A point had then been reached at which the production considerably exceeded the consumption, due in part to the desire of the spirit trade to meet the increased demand for "matured" spirits and in part to the fact that an excessive amount of capital had, owing to the increased popularity of Scotch whisky, been attracted to the distilling industry. This overproduction led to a vast increase in the quantity of spirit remaining in warehouse. In 1906 production and consumption were about equal and the quantity of spirit in warehouse represented roughly five years' supply.

Of late years the consumption of spirits has shown a marked decline. Whereas in the opening years of the century it reached approximately one gallon per annum per head of the population, in the subsequent decade it fell to 0·75 gallon and as will be seen from the above table this decrease has continued. This is doubtless due, in part, to the high duties, but in all probability it may be attributed in some measure to a change in popular taste.

The number of distilleries in the British Isles has fluctuated in a manner corresponding to the consumption of spirit, but the variation has been chiefly in Scotland.

In 1906 the respective totals for the three countries were: Scotland 150, Ireland 28, England 8. Since that time there has been a steady decrease, the number for Great Britain and Northern Ireland being 140 in 1923 and 121 in 1926. Of the spirits distilled in the United Kingdom Scotland produces approximately one half, England and Ireland being responsible for the remainder in about equal proportions. The apparent anomaly between the number of distilleries and the quantity of spirit produced in the different parts of the kingdom is explained by the fact that the great majority of the distilleries in Scotland and Ireland are small pot still distilleries, whereas the English plants are all of considerable capacity. Illicit distillation has almost ceased in Great Britain.

The spirit produced in the United Kingdom is made almost exclusively from malt, unmalted grain (chiefly maize, rye, barley, wheat and oats) and molasses. The relative proportions of malt to unmalted grain have shown a slight upward tendency. On the other hand the quantity of molasses employed has increased very largely, owing mainly to the fact that home made spirit has largely displaced the foreign article for several industrial purposes and particularly for methylation.

In the Dominions the consumption per head of the population shows in some parts a tendency to decrease, thus, for Canada the figure for 1921 was 0·857 gal. and for 1927, 0·323 gal., and New Zealand 0·790 in 1921 and 0·518 in 1925, but in Australia there has been an increase from 0·36 gal. in 1921–22 to 0·44 gal. in 1925–26. The sale of alcoholic beverages is now prohibited in the United States of America. In other countries the consumption of spirits per head of the population, expressed in litres of absolute alcohol, has been as follows:—

Year	Denmark	Norway	Sweden	Switzer-land	Germany	Holland	Belgium	France
1920 .	1·51	..	3·00	2·02	0·7	2·58	1·24	2·26
1921 .	1·51	0·44	2·40	2·16	1·0	1·45	0·99	2·09

Manufacture.—The manufacture of spirits can be divided into two or three stages according to the materials used. If they are of a saccharine nature (*e.g.*, grape juice or molasses), the first step is the conversion of the sugar into alcohol, the second operation being the separation by distillation of the alcohol and, incidentally, other volatile substances from solid matter which may be present either in suspension or in solution. If the raw material is of a farinaceous character, the preliminary stage is the conversion of the starch into sugar.

Brandy.—The manufacture of genuine brandy, although requir-

ing great care in order to obtain a high class product, is not a complicated process. The quality of the brandy produced depends primarily upon the character of the wine employed, whilst the degree of excellence of the spirit offered for sale depends in great measure on the experience of the manufacturers in blending the products of various distillations The character of the wine is therefore of the first importance and is dependent upon the soil, climate and methods of cultivation The soil of the Cognac and other districts of France is particularly suitable, and brandy of excellent quality is also distilled from wine of British Empire origin In France the cultivation of the vine has improved since the replanting of the vineyards after their devastation by the phylloxera epidemic of 1875–78 The best French brandies are obtained from the Charente wines which, although possessing no particular virtue as such, are peculiarly suitable for the production of a spirit of a fine and delicate flavour The wines of other districts, although more highly flavoured, are not so suitable for the production of brandy The type of still and method of distillation depend upon the character of the wine employed In Charente, where as stated above, the most suitable wine is obtained, a simple pot still having a capacity of not more than 200 gal is usually employed, the distillation being carried out very slowly The spirit first obtained—*brouillis*—is redistilled to give a product of a higher strength—*bon chauffe* In other districts where the wine is not so suitable a more complicated apparatus is employed This includes a distilling column which renders possible a higher degree of rectification and the removal of fractions of the distillate which are considered undesirable

Rum—This spirit may be divided into two main classes "Jamaica" and "Demerara " The greater proportion of the former is of the type usually imported into Britain It is prepared by the fermentation of a wash consisting of cane molasses, scum drawn from the solution during the manufacture of cane sugar, "dunder" the viscous mass obtained from the bottom of the still during the previous operation, and "megass," the last, which is the fibrous part of the crushed cane, being added to promote fermentation The fermentation is slow, extending to 12 days or even longer. When this operation is complete the spirit is distilled off in a pot still There are two other types of Jamaica rum That intended for local use is obtained by rapid fermentation and is of comparatively poor quality The third, known as "German rum" has a very strong flavour and is used for blending purposes or for imparting to plain spirit the characteristics of ordinary rum Demerara rum is lighter in flavour than the Jamaica varieties and has a lower proportion of secondary ingredients It is usually prepared by the fermentation of molasses dissolved in water, the spirit being then distilled off in patent stills or in pot stills of a type more complicated than those generally used in Jamaica For the manufacture of industrial spirit, *see* ALCOHOL.

Spirits of Farinaceous Origin—The raw materials used for these include cereal grains, such as barley, rye, oats, wheat, maize, etc., which produce whisky, "corn brandy," vodka, plain spirit and industrial alcohol Potatoes are used in the manufacture of industrial alcohol The first stage in the preparation of spirit from starch is the conversion of the latter into dextrine-maltose and intermediate products This is accomplished by the action of a diastatic ferment such as that present in malted grain (*see* BREWING) or secreted by certain living organisms, or by an acid such as sulphuric acid The latter process is little employed at the present time. The materials employed by the distiller and the methods of preparation and treatment to which they are subjected before and after entering the distillery are in some respects similar to those employed by the brewer. The great difference, apart from the actual process of distilling, is that, whereas the object of the brewer is to produce beer, of which alcohol forms only a relatively small proportion, the distiller, broadly speaking, desires to produce alcohol.

Malting.—Where malt is employed as the main raw material, as for instance in Scotch pot still and some other whiskies, the process of preparation usually does not differ widely from that used in making brewers' malt. The spirit manufacturer, however, need not be so particular as to the quality and character of the malt, which need only be sound and contain a high percentage of starch to serve his purpose Barley intended for operations in a patent still is usually "steeped" and "floored" for periods longer than in brewery malting In distilleries where barley malt is used not as a principal raw material but primarily as a diastatic agent, —for instance in potato and maize distilleries—these two processes are particularly lengthy, the steeping being prolonged until the increase in weight due to the absorbed water is about 40 or 45%. The brewers' malt is almost invariably highly kilned in order to restrict the diastatic power As the object of the distiller is to produce the highest proportion of alcohol possible he does not desire to restrict the diastatic power in this way, and if possible uses a green malt The malt whisky manufacturer, however, depends in great measure upon the kilning process to yield the characteristic flavour of his product For this reason, and also because of the difficulty of obtaining green malt in hot weather, a malt is often used which has undergone a mild kilning process in which a temperature of 130° F is seldom exceeded In order to reduce the danger of bacterial infection at subsequent stages some antiseptic such as lime is introduced during the steeping

Although green or low dried barley malt is the saccharifying agent usually employed both in the United Kingdom and on the Continent of Europe, malts prepared from other materials are not infrequently employed

Oat malt, notwithstanding its low transforming power, possesses certain advantages, inasmuch as it is easily and rapidly prepared, it acts very quickly in the mash tun, and its diastatic power is well maintained during fermentation Rye is best malted in conjunction with a little barley or oats, as it otherwise tends to superheat and to grow together in a tangled mass

Mashing and Fermentation.—The details of this stage of the process are, in the case of the malting, designed to produce the highest possible yield of alcohol consistent with the commercial requirements, such as flavour and aroma, of the particular trade in which the distiller is engaged In order to accomplish this the mashing takes place at a low temperature, the wort thus remaining unsterilized and the diastatic action continuing during the fermentation period The problem for the distiller is to raise the mash to a temperature as high as possible in order to restrict the bacterial fermentation to which the wort is liable, whilst keeping it sufficiently low to prevent the destruction of the diastase The method employed varies according to the nature of the mash and the quality of the spirit desired, but in general principle is governed by the requirements indicated The micro-organisms most to be feared are those belonging to the class of fission fungi (*schizomycetes*) such as the butyric, lactic, mannitic and mucic ferments In order to avoid bacterial fermentation it is necessary either to let the wort "sour" naturally (lactic acid being chiefly formed) or to add a small quantity of acid (formerly sulphuric acid was frequently employed) to it before pitching the yeast Such a condition is favourable to the free development of the desirable types of distillery yeasts but restrictive to the growth of brewery yeasts and especially of bacteria.

In order to facilitate the proper control of the formation of the acid the souring process is usually carried out in a small separate mash so that when sufficient acid has been produced the temperature of the liquid is increased and the acidifying process stopped The souring mash is often inoculated with a special variety of lactic acid bacteria—a pure culture of B *acidificans longissimus* The optimum developing temperature of this organism is about 104° F but it is better to keep the wort at 122° F, for at that temperature practically no other bacteria is capable of development When lactification is complete the temperature is raised to 165° F and after cooling the mass it is pitched with yeast and added to the main wort. Sometimes lactic acid is added instead of being produced naturally Hydrofluoric acid and its salts are also sometimes used with very satisfactory results

Much of the yeast used in British and Irish pot still and in some patent still distilleries is obtained from breweries In order to obtain a more rapid and complete fermentation a special type of "German yeast" is often used It is usual to "pitch" at about 80° F and then to cool slowly to 60° F. As fermentation develops

the temperature again rises naturally to about 85° F. In malt whisky distilleries the original gravity of the wort is usually about 1·050 to 1·060, but in grain and potato distilleries it is often higher, being sometimes as high as 1·11 in Germany. In the production of industrial alcohol other methods, involving the use of a pure culture of a micro organism in a sterilized wort and then a pure culture of yeast, are adopted. For details of these *see* ALCOHOL IN INDUSTRY.

Distillation.—This may be described as a process by which, on the application of heat, one substance can be volatilized from another and recovered by subsequent condensation. Thus, a solvent, such as water, can be separated from solid matter which it holds in solution, or two liquids, boiling at different temperatures, can be freed one from the other. In the case of spirituous liquors the primary object of distillation is the separation, as far as possible, of the alcohol from the non-volatile constituents of the wash. Incidentally other volatile substances, such as water and products of fermentation other than ethyl alcohol are distilled off, but the proportion of these is reduced by further distillation and by various elaborations of the apparatus in which the process takes place. The modifications thus introduced vary according to the materials used and the type of spirit it is desired to produce. The essential parts of a still are the vessel in which the mixture can be heated, a tube or still head to carry off the vapour, a condenser for cooling and thus reducing the vapour once more to the liquid state, and a vessel for receiving the liquid.

Pot Still.—This apparatus embodies these features with the minimum of elaboration. Experience has demonstrated that, for wines producing the finest brandies, the most simple form of still is the best. For the distillation of wines which do not produce brandy of the finest quality more complicated apparatus is employed in order to facilitate higher rectification. In Scotland the pot stills are somewhat larger and are adapted more particularly to the requirements of the whisky industry. They vary in size from about 3,000 to 8,000 gal., the usual capacity being 5,000 to 6,000 gallons.

The pot stills used in Ireland differ materially from the Scotch stills. They are very large, ranging up to 20,000 gallons. A characteristic feature is the great length and height of the "lyne arm," *i.e.*, the pipe connecting the still with the condensing coil. This lyne arm generally runs up vertically from the still for a distance of 10 to 20 ft., then horizontally for another 30 to 40 ft., again vertically for 10 to 20 ft., and is then connected to the condenser. The horizontal portion of the lyne arm lies in a shallow trough fitted with a water supply, and the temperature of the

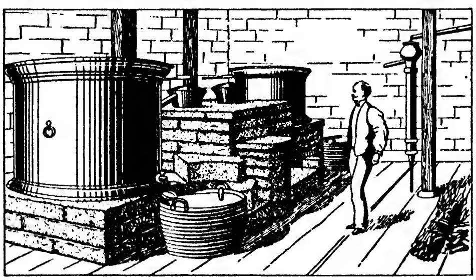

FIG. 3.—OLD COGNAC POT-STILL

spirit vapours prior to their passing to the condenser may thus be regulated at will. According to the length and height of the lyne arm and the temperature of the water jacket, more or less of the vapours condense and are carried back to the still by means of a pipe. This return pipe is fitted with a cock which enables the distiller to regulate the flow. Occasionally there is a further return pipe for the condensing coil, but this is not usual. The advantage of this form of plant is that it is possible to work up far greater quantities of wash and to obtain a much higher rectification in a single operation than is possible in the case of the pot still. It will be noticed that in this case there is no return pipe from the lyne arm.

Patent Still.—This was designed by Aeneas Coffey in the early part of the 19th century with a view to accomplishing in one process that which necessitates several operations in the pot still, of economizing time, fuel and material, and also of obtaining at will a spirit of higher purity than that which can

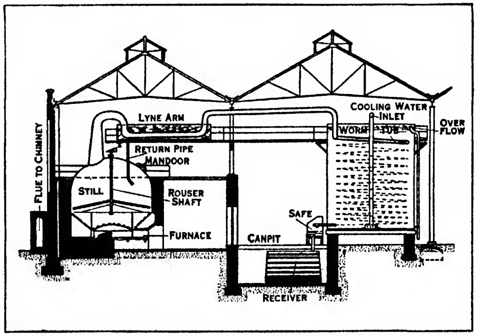

FIG. 4.—DIAGRAM OF SINGLE TYPE OF IRISH POT-STILL PLANT. (JOHN JAMESON'S DISTILLERY, DUBLIN)

be produced by the older and more simple form of apparatus. It is the still usually employed for the production of Scotch and Irish grain whiskies. It can, however, be adapted for the distillation of a spirit intended for methylation, or for the production of spirit having a high degree of strength and purity. In the preparation of spirit approximating closely to absolute alcohol, however, the product of the patent still must undergo further treatment and rectification. In certain details the Coffey still since first devised has undergone certain modifications, but in general principle it remains unchanged.

The still shown in the accompanying illustration (fig. 5) is a type designed by Messrs. Robert Willison of Alloa for Scotch grain whisky distilleries. This Coffey still is a double still consisting of two adjacent columns, termed respectively rectifier and analyser. Both columns are subdivided into a number of chambers by perforated copper plates. The main structure is of wood firmly braced with iron. Each compartment communicates with the next by means of a drop pipe standing slightly above the level of the plate and passing downwards into a cup, which forms a water seal or joint. Each compartment is also fitted with a safety valve in case of the plates choking or of the pressure rising unduly. At the beginning of the operation both columns are filled with steam at a pressure of about 5 pounds. The steam at the base of the analyser passes upwards through it, thence to the bottom of the rectifier by means of the pipe B (termed the low wines vapour pipe), and then up through the rectifier. When both columns are filled with steam the wash is pumped up from the wash charger through the copper pipe A nearly to the top of the rectifier, which it enters at the point A. The pipe A runs from the top to the bottom of the rectifier, forming a double bend in each compartment, and the wash (contained in the pipe) travels down in a zig-zag course until it reaches the base of the rectifier at the point C. From here (still remaining in pipe A) it is pumped to the top of the analyser, where it emerges from the pipe and covers the plate of the top compartment. As there is an upward pressure of steam the wash is not able to pass through the perforations of the copper plate forming the base of the compartment, but collects until its level reaches the top of the first drop pipe. Through this it passes into the cup on the plate below and so out on to the next plate. The drop pipes being trapped by the cups, the steam cannot pass upwards through the former. In this way the wash passes through compartment to compartment on the analyser until it reaches the bottom, and then passes out by means of the spent wash siphon. The steam, on its passage

up through the analyser, carries with it the alcoholic vapours and other volatile matters contained in the wash. The alcoholic vapours pass from the top of the analyser to the bottom of the rectifier, and then upwards through the latter from compartment to compartment In so doing they are gradually cooled by the wash flowing down through the pipe A This gradual cooling causes the less volatile constituents to condense and so to

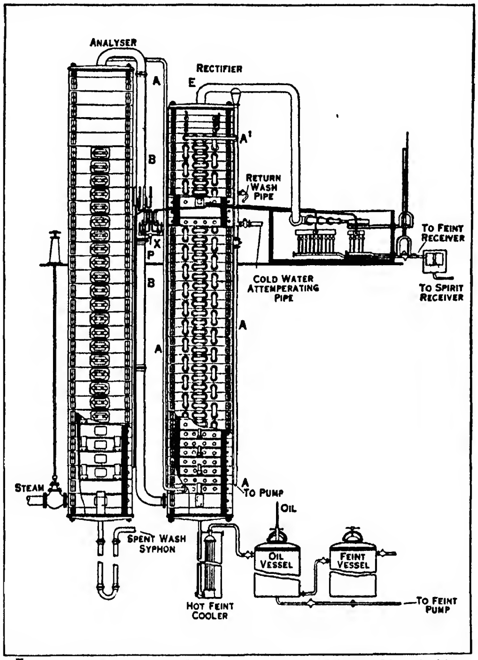

FIG 5 —DIAGRAM OF COFFEY STILL (R WILLISON AND CO . ALLOA)

flow downwards through the column until they reach the base of the rectifier At a certain point in the upper part of the rectifier (marked S in the illustration) the bottom of the compartment in question is formed not of a perforated plate, but of a stout copper sheet, pierced by a fairly wide pipe, which stands up about 2 in above the level of the former This is termed the spirit plate It is so placed that the alcoholic vapours condense either on or immediately above it The alcohol passes out from the spirit plate chamber from one of the two pipes shown in the illustration (either to the spirits or to the feints receiver as the case may be), and is then further cooled, in order to complete the condensation, by being run through coils immersed in flowing cold water.

In order to render the condensation still more perfect the upper chambers of the rectifier are fitted with coils through which cold water is passed The vapours condensed by this fall upon the spirit plate The vapours which have an appreciably lower boiling point than ethylic alcohol, such as the aldehydes, together with a large volume of carbonic acid gas derived from the wash, pass out of the top of the rectifier by means of the "incondensible gas" pipe E, and thence to a separate condensing coil The spirit retained is of high strength, generally about 64 over proof. The less volatile constituents of the wash, generally termed "fusel oil," which pass out of the base of the rectifier, are cooled and then passed to the oil vessel. After the apparatus has been worked for some time the fusel oil which floats in a layer on the top of the contents of the oil vessel is skimmed off. The watery layer from the oil vessel, which still contains a little alcohol, is again passed through the apparatus to remove all of the latter

The distillation is controlled by an operator standing on the platform P. The operator is able by means of the sampling apparatus X to determine the quality and strength of the spirit and of the wash He is able, by regulating the quantity of steam admitted to the apparatus, by modifying the rate of pumping, and by running the spirit either to the spirit or to the feints receiver, as the case may be, to control the strength and quality of the product in much the same manner as does the pot still distiller

By-products of Fermentation and Distillation.—Although the principal ingredient of all spirits is, of course, ethyl alcohol diluted with different proportions of water, there are present in varying quantities, other substances which impart to each type its individual characteristics and afford a means of determining its origin. These by-products are formed mainly during fermentation, but are also to a certain extent pre-existent in the raw materials or may be generated during the operations preceding and succeeding fermentation. Their nature is complex and varies sensibly according to the raw materials and the methods of malting, mashing, fermentation and distillation. The by-products or secondary ingredients may be classified as follows· (a) higher alcohols, (b) esters, (c) fatty acids, (d) fatty aldehydes and acetals, (e) furfural, (f) terpene, terpene hydrate and ethereal oils, (g) volatile bases.

The higher alcohols—commonly known as fusel oil—consist of mixtures of fatty alcohols ($C_nH_{2n+1}\cdot OH$) containing three or more atoms of carbon. The fusel oil in British pot still spirits is chiefly composed of amyl, butyl and propyl alcohols, their relative proportion being in that order, but in the preparation of British spirits in the patent still the amyl and butyl ingredients are to a great extent removed and the propyl is the predominating higher alcohol in the finished product. The butyl in the grain spirits, as also in brandy, is chiefly the normal, whilst that contained in spirit produced from potatoes is chiefly iso-butyl The esters, formed by the interaction of alcohols and acids, chiefly during the fermenting and distilling operations, consist almost entirely of fatty acid radicles in combination with ethyl and to a minor extent amyl alcohol Ethyl acetate (acetic ester) is the chief of these, others being ethyl valerate, butyrate and propionate Oenanthic ether (ethyl pelargonate) although only representing a small proportion—about one per cent—of the total secondary ingredients present in brandy, is one of that spirit's most pronounced characteristics The acid present is chiefly acetic—formed by the oxidation of the ethyl alcohol—but small quantities of other acids are also found Furfural, which is probably formed chiefly from the pentoses contained in the wort, occurs to a greater or less extent in most spirits, but it is particularly characteristic of pot still products.

Effect of Maturing.—It is a fact which has been recognized for centuries that alcoholic beverages improve with age There is little doubt that this improvement is due to changes in the character and relative proportion of the secondary ingredients, although the exact nature of the changes is not fully understood They are undoubtedly dependent in some manner upon the ventilation of the containing vessel, as no perceptible alteration takes place when the liquid is stored in glass bottles The degree and rate of maturation depend upon the character of the original spirit, the type of cask and the conditions existing in the place of storage Generally all the secondary ingredients except furfural tend to increase with age, although, as their proportions are usually expressed in relation to the ethyl alcohol present, the loss of some of the latter by evaporation may result in an apparent increase which is relative rather than actual Thus in a very damp cellar the spirit will lose very little in volume, but such loss as occurs will be almost completely confined to the alcohol. In a dry cellar the volume decreases more rapidly, and the loss of water as compared with alcohol is relatively greater Change in the character of the spirit is also caused by extraction of materials from the wood of the cask There is a limit of time to the beneficial effect of the ageing of the spirit, and when that has been reached the contents of a cask should be immediately bottled, otherwise deterioration will take place.

Physiological Effects.—The nature of the physiological effects produced by the ingestion of spirits varies considerably not only according to the class of spirit (*i.e.*, whether whisky, brandy, rum, etc.) consumed but also with its age and general condition, and there is no doubt that the causation of these phenomena is intimately connected with the nature and quantity of the secondary ingredients. Commenting on a statement in Bailey's *Book of Sports* to the effect that wine and brandy had a tendency to make a man fall on his side, whisky to make him fall forward, and cider and perry to make him fall on his back, Sir T. Lauder Brunton in giving evidence before the Spirits Committee in 1891 suggested that these statements, if correct, might indicate definite injury to various parts of the cerebellum. He was inclined to believe that the varying effect of different spirits might be due to the specific action of the different products on the separate nerve centres.

Numerous investigations have been conducted to determine the effects of the various by-products. Thus Dujardin-Beaumetz and Audige found that the pig, whose digestive organs are very similar to those of man, when fed for 30 months with pure alcohol, suffered no ill effects, whereas when similarly treated with imperfectly purified spirit (whether derived from beet, potato or grain) suffered considerably. The same investigators, experimenting on dogs, found that the lethal dose of various alcohols was: ethyl 5 to 6 grammes, per kilo body weight, propyl 3·75 grammes, butyl 1·8 grammes and n-amyl 1·5 grammes. Brunton and F. W. Tunnicliffe demonstrated a poisonous action of furfural upon man and, comparing the after effects upon animals of spirits containing, and freed from, aldehydes, found certain important physiological differences between them.

It is important therefore that the spirit manufacturer should adopt all possible precautions to obtain a product which, whilst satisfying commercial requirements, will ensure the minimum possibility of harm to the consumer. The ordinary precautions which at all times should be followed include clean stills and apparatus, a good water supply, high-class and appropriate materials, and careful control of all operations during mashing, fermentation and distillation. The removal of acids can be effected by neutralization with an alkali in the still, whilst for the elimination of fusel oil treatment with charcoal is the common method.

Many processes have been suggested for the artificial maturing of spirits. The most practical are those embodying the passage of hot or cold air, oxygen or ozone through the liquid. Miels and Barr suggest the maturation of new whisky by the addition of a little sherry and a minute trace of sulphuric acid (subsequently neutralized by lime). Hermite suggests a method which consists essentially of adding an electrolysed solution of common salt to the spirit and subsequently redistilling. R. P. Pictet, by cooling a new brandy to $-80°$ C, is said to have obtained a liquid which had apparently acquired the properties of a 12 year old spirit. None of these methods, however, appears to have been devised with a view to removing those substances which render the new spirit objectionable as compared with the old. A patent taken out by J. P. Hewitt is of interest, however, as by distillation with phenyl-hydrazine sulphonate of soda he effects the actual removal of furfural and aldehydes from the crude spirit.

(F. G. H. T.)

SPIRITUALISM, a name used by some philosophers, instead of "Idealism," to signify a philosophic attitude or point of view about the universe opposed to materialistic philosophy, and to imply that the ultimate reality is more fundamentally on the mental or ideal side of things rather than on that which appeals most directly to the senses as the behaviour and modifications of matter. But the name "Spiritualism," or "Spiritism," is more usually employed to signify a growing persuasion on the part of certain people that the activity of human beings is not entirely limited to the use they make of their bodily or material organisms on this planet. It is held that those organisms were constructed by an animating principle which having entered into relation with matter for the purpose of developing an individuality can continue long after the temporary material body is worn out or otherwise resolved into its elements; and, further, that the personalities thus brought into existence shall carry with them their memory, character, tastes and affection, which they had developed here while in association with matter, and shall be able under certain limitations to guide and influence terrestrial affairs in co-operation with those still living on the earth. This may be taken roughly as the spiritualistic interpretation or explanation of certain obscure phenomena which have occurred sporadically from time immemorial, and which may be said to constitute the phenomena of spiritualism.

General Principles.—There is however a group of investigators who, while they accept the phenomena on the grounds of experience, are not prepared to accept the explanation in terms of human survival, and who therefore dislike the term "spiritualism," preferring to employ some non-committal term such as "metapsychics" or "parapsychology"; meaning thereby a study of those obscure phenomena which lie outside the region generally accepted as orthodox psychology, and which suggest a possible extension of human faculty in directions not as yet understood. The object of these investigators is first to verify and then to study the facts, so as to disentangle the laws which regulate them, and seek to bring them within the recognized domain of organized human knowledge, or else to expand that domain so as to include them. This is called psychical research.

A third group of scientific men not only discard the spiritistic hypothesis, but feel a doubt about the facts, regarding them rather as the outcome of savage superstition and folk-lore, and therefore unworthy of scientific attention.

The whole subject therefore at the present time is a debatable one, on which there are many more or less legitimate differences of opinion. On the whole however there is a general consensus of agreement among those who have devoted time and attention to the subject that some of the phenomena are genuine; so that in time they must be accepted and gradually incorporated into the main body of science. They admit however that the investigation is conducted under difficulties, inasmuch as the phenomena cannot be produced at will, and because the facts are largely dependent on the good faith and careful testimony of those who experience them, or who are allowed to witness them under sufficiently strict conditions. In so far as the phenomena appear to be dependent upon the activity of agents whose existence is not generally recognized, and who have the spontaneity and it may be the capriciousness characteristic of live creatures, the phenomena differ in many respects from the purely mechanical behaviour of atomic groupings and material bodies, such as form the customary stock-in-trade of astronomers, physicists and chemists. They appear likely to belong more to the domain of biology, or even of anthropology, when those sciences are sufficiently enlarged to include them. Meanwhile there is a great body of testimony as to their actual occurrences, which cannot properly be ignored.

But, again, this testimony depends on the utilisation of people endowed with exceptional faculties; and these faculties are occasionally imitated by those who do not really possess them—a procedure which must be stigmatized in the strongest terms as fraudulent. There are others who, while possessing the faculties in a small degree, are tempted to enlarge and extend the results by normal supplement: a tendency which has to be constantly guarded against, for, if unchecked, it tends to bring the whole subject into disrepute.

Meanwhile, however, a body of careful investigators, notably those who founded in London the Society for Psychical Research, and others who have joined them or formed similar Societies, have accumulated a great mass of evidence in favour of the phenomena; and the enquiry is still proceeding.

Assuming, on the strength of the evidence, that human faculties are not so limited as was at one time thought, and that these obscure phenomena actually occur, they may be classified into two great groups:—(1) the mental, or purely psychical branch, concerned with the reception of ideas and information,—information which could not have been normally acquired by the operator and therefore has to be styled supernormal; and (2) the physical branch, which concerns the production of effects in ordinary

matter by apparently a supernormal extension of physiological processes

To the first group belong such subjects as may be summarized under the heads telepathy, clairvoyance (*qq v.*), lucidity, trance utterance, automatic writing, premonition, xenoglossy, psychometry, and other apparent extensions of receptive faculty occasionally summarized under the rather question-begging term of "cryptesthesia" It is chiefly on the strength of these mental phenomena that the hypothesis about the continued activity of the discarnate has grown up. For most of the communications so received purport to come, and certainly have the superficial appearance of coming, from intelligences no longer in the flesh, who desire to send messages of condolence, sympathy, and assurance to surviving relatives, and to furnish proof of their continued activity To this group must also probably be added the visual and auditory hallucinations (if that term can be properly used) which many people have experienced in the form of apparitions, or other apparently sensory manifestations, of the people concerned It has been found that these appearances, or voices, are not limited to those of dead people, as they can be traced sometimes to the unconscious influence of living people, when they are either asleep, or in some danger, or subject to some strong emotion And these are called phantasms of the living

The discovery of telepathy, that is to say the transference of thought or of ideas or emotions from one person to another without the use of any of the normal means of communication—a power which has been established by direct experiment as possessed by some people—tends to throw light upon these apparitions, and indeed upon the whole spiritistic hypothesis For if it is possible for one mind to influence another without the use of the material mechanism commonly employed, it tends to demonstrate an independence between mind and body which cannot fail to have important implications Though neither the vocal cords nor any other muscles are used for transmission, although neither the eye nor the ear, nor any of the other senses, are used for reception, yet, since some brain process must at least indirectly be involved, it is just possible that telepathy may be due to some unknown method of transmission between brain and brain But no evidence has ever been adduced, at least none of any trustworthy character, for the existence of what have been called "brain waves." And many circumstances connected with telepathy seem to render it unlikely that a physical method of transmission, even of an etheric kind, could be utilised for the purpose of transmitting information, even though something analogous to brain waves existed The great distance over which thought-transference occurs, and its apparent independence of obstacles are against such a hypothesis For although the analogy of wireless telegraphy is often adduced, it must be remembered that we have no means of apprehending etheric waves except by the use of definite instruments (a) for producing such waves in conscious and prearranged manner at one end, and (b) of detecting and transmuting them into sound or other mechanical movements at the other Telepathy occurs without such instruments (assuming that it occurs at all), and nothing that has been detected in a screened organ like the brain makes it able to act as either a receiving or a transmitting instrument except through the agency of the nerves and muscles Consequently the most natural hypothesis is that telepathy is a purely mental phenomenon, an action of mind on mind apart from the bodily organs; though the ultimate realization and demonstration of the occurrence must of course depend on the normal methods of testimony and record.

Now mental activity apart from the body is of the essence of the spiritistic hypothesis: and there would be no reason to object to the idea that deceased people can communicate information provided the great and fundamental step is taken of assuming that they still continue to exist Conversely, the fact, so frequently testified to, that such communications are actually received, whether in the form of apparition or audition, or of automatic writing, or trance speech, or any other way, would, when established, also strongly support or even demonstrate the continued activity of the apparently operating personality. Hence it may be held that the discovery of telepathy rationalises and renders more acceptable many of the asserted occurrences which otherwise would seem absurd and incredible. If an apparition were regarded as an objective reality, all manner of difficulties would arise about the details But if it is only a mental impression, perhaps roughly analogous to an image in a looking-glass, although produced in some obscure and not in a simply optical manner, difficulties tend to disappear The image can then be thought of as something not "seen" at all, but mentally reconstructed in accordance with a telepathic impulse which, indirectly through the mind, influences that part of the brain which is accustomed to receive an optical, or it may be an auditory, impression through the nerves. For, on any hypothesis, the brain and mind are closely interrelated, and a mental impression cannot be testified to or realised without the operation of the brain-nerve-muscle system

PHYSICAL PHENOMENA

On the spiritistic view—that is to say granted the working hypothesis that individuals once generated and isolated from a cosmic reservoir of life and mind, by means of their association with matter, shall continue to function as mental or psychic entities—it is fairly easy to suppose that they may be able to influence other minds, especially now that telepathy is fairly established as a *vera causa*, and can thus presumably cause inspiration, and convey ideas or information For it may reasonably be assumed that they have a wider outlook than when limited by the flesh; and, being also less restricted in time, that they may be in occasional touch with greater and higher intelligences on their side Thus not only could ordinary lucidity and clairvoyance and even premonition be accounted for, but also the more valuable inspirations of genius.

It is not difficult to suppose that the organisms of people thus acted upon could be stimulated to produce such muscular movements as speaking and writing, or any other familiar bodily activity The influence exerted on such people might still be considered purely mental, and might be thought likely to operate most freely on the recipient organism when the medium or possessor of that organism is normally in a state of unconsciousness or partially suspended mental activity, but it would hardly be expected that the influence would be such as to produce physical phenomena beyond the capacity of the ordinary unstimulated organism. Nevertheless there is a large and growing body of evidence for the occurrence of even physically supernormal phenomena. Undoubtedly this evidence must be scrutinised with extreme care because of its unusual character, so that the further question whether in some cases these phenomena are produced by the latent power of the normal individual, or whether it is dependent on a stimulus received from some other intelligence, may remain an open one, to be considered and classified later when the facts are thoroughly established

The physical phenomena which have thus been seriously vouched for are such as the following. First, movement of objects without apparent contact, in other words, the displacement of matter at some distance from the boundary of the normal organism, with no perceptible link, and therefore out of the normal reach of the muscles. This is known as telekinesis or locomotion of objects at a distance A modification of this phenomenon is the moulding or rearrangement of matter so as to produce an imitation of known objects, after the manner of a sculptor or a painter, so as to produce simulacra of hands and faces and other parts of the human organism out of any material available Another fact which is testified to is the rearrangement of the particles on a photographic plate, so that when the plate is developed in the ordinary way a supernormal image of some kind appears upon it, whether it be writing or a human or animal figure It is further asserted that if no suitable material is provided, or cannot be collected, some organized material can be drawn, either from the medium or from any of those present, of apparently a living or protoplasmic nature, remaining still associated or connected with the organism from which it is drawn; and that this externalised protoplasm is then independently manipulated so as to display a likeness of some departed person, more or less unsatis-

factory and incomplete, but far beyond the normal power of the medium from which the material is drawn. Such exteriorised protoplasm is now generally known as ectoplasm. It only lasts a short time, and has to be returned to the body whence it came. But meanwhile it is said that it can achieve many odd results, among others that it is able to produce "direct voice," to move about, and also to exert considerable muscular force, thus effecting the locomotion of objects already spoken of as telekinesis.

The testimony of investigators suggests the idea that this extraneous material is worked by an intelligent mind, much in the same fashion as our own bodily organisms are normally worked by our own minds, and that its activities show will and intention analogous to the will and intention of our own movements. We know too little about the relation between mind and matter to stigmatise such an hypothesis as intrinsically absurd: we must be guided by the facts. But the asserted facts are so extraordinary, and physiologically so incredible, that the evidence will have to be of a strong and cumulative character before such an idea can be accepted. Nevertheless it is mainly by physiologists well acquainted with the difficulties of such an hypothesis that it has been most responsibly put forward. And there is considerable testimony from some physiologists in Europe that, however odd they may be, phenomena which suggest this kind of activity are definitely found to occur. The ectoplasm appears to have varying consistency, sometimes being visible only, sometimes tangible only, sometimes neither, and occasionally both. Ectoplasmic formations have been photographed, though it is said that they can sometimes only be photographed in ultra violet light, and with the use of a quartz lens.

One special difficulty surrounding this investigation is that the ectoplasmic material seems to be manipulated or controlled through an etheric connecting link, and that a tremor or vibration in the ether, of the kind which normally excites the retina of the eye, is detrimental to its activity; so that in most ordinary cases operations of this kind have to be conducted, or seem to be easier, in the dark—a circumstance which makes investigation specially difficult and unsatisfactory. It seems to have been found however that red light is not so deleterious as the brighter illumination of higher frequency, and that with due preparation the ectoplasmic formations can be photographed by a flashlight before they are thereby disintegrated. Moreover it is asserted that in the case of some exceptionally strong mediums, some of the effects have been produced in full daylight.

The force exerted by the ectoplasm can be quite considerable. For instance a table can be raised completely off the ground; and the weight of a man clambering on the table need not be sufficient to bring it down. The forces have sometimes been measured by spring-balances: and an attempt has been made to weigh the medium from whom ectoplasm has hypothetically been removed, with the result that the normal organism is said to have lost weight corresponding to that of the material which has been extruded and accumulated on another balance.

In quoting such assertions it is not to be supposed that they are as yet fully accepted; but they indicate the lines on which investigation should proceed. The hypothesis gives a link on which the phenomena can be threaded together, so as to give them a sort of coherence, which further experience may either substantiate or discard.

Still More Obscure Phenomena.—All the movements and mouldings hitherto spoken of are within the power of normal individuals, if they are allowed free use of their limbs. There is no difficulty in levitating objects or people, or in moulding images and simulacra. Hence the evidence for the occurrence of these things in a supernormal manner must depend on whether the medium and all those concerned are under complete control. Much of the experimentation is complicated by this necessity.

But there are certain other phenomena asserted which are not of a normal character, and could not be produced normally if the operator were free,—phenomena which might be spoken of as miracles. The one most commonly attested to is the immunity to damage or destruction by extreme heat. It is said that certain people can hold flaming or red-hot coals in their hands without feeling pain and without being singed; that this power can be conveyed to other people under certain conditions; and that even fabrics, such as hair or cambric, can be rendered temporarily immune to fire. Travellers tell us of native races who can walk through fire, or over hot coals, without injury, when in a state of exaltation. Heat is known to be a rapid vibration or tremor among the particles of a body, and it is difficult to see how the molecular or chemical changes normally associated with such tremor can be suspended. But again, when there is sufficient confirmation, we must be prepared to accept the facts, whether we feel able to understand them or not.

Another phenomenon of what is popularly called a miraculous character, has been often asserted to occur, namely the passage of a solid body into or out of a closed cavity; as, for instance, the introduction of an object into a closed room, such object having been previously known to be outside; a phenomenon known as an "apport." Verification of such a fact as that is singularly difficult, especially when the enclosure is, like a room, such as can readily be normally opened; and, like all the rest of the phenomena, it must depend with excessive cogency on the good faith of all concerned. Indeed good faith alone might not be sufficient. Before accepting a thing like that, one would have to allow for hypnotic or other influence.

A modification of this "passage of matter through matter," as it has been called, is the linking of two entire rings together, or the tying of knots on an endless string. These things have been testified to, but are hardly as yet even tentatively accepted. The disintegration and reconstitution of matter has been contemplated as a working hypothesis by the few who do accept them; while others have taken refuge in a fourth dimension of space, in which a globe is no more a complete enclosure than a circle is in three dimensions. A quadruped is fully confined when enclosed in a village pound, but a bird is not. The parable is obvious.

It is however hardly worth while to seek for some mode of conceiving or formulating an explanation until the facts are established. The object of this article has been, first, to show the kind of assertions which are made, and then to indicate the kind of lines on which a rational explanation may be looked for; at least in connection with those for which a prima facie case has been established; and, next, to suggest that an enlarged psychology, and possibly an enlarged physiology,—possibly even an enlarged physics—will have to take into account and rationalize a number of phenomena which so far have been mainly disbelieved or ignored.

Historical Summary.—Although spiritualistic phenomena have been testified to by all nations and peoples, although they are spread over the historical documents collected in the Old Testament, and have continued down to the time of John Wesley and later, it is usual to attribute the rise of what is called Modern Spiritualism to occurrences which took place in America about the middle of last century, when they began to attract rational attention; passing through a time of much scepticism and contumely, until they have emerged in the moderate and cautiously sceptical atmosphere of today.

Examples of mediumistic and prophetical incidents are common from the time of the Hebrew Patriarchs downwards. David and the other Kings did not hesitate to consult seers, and, sometimes unwisely, regulated their conduct accordingly. The episode of the infant Samuel is a good example of the phenomenon called the direct voice. In the Graeco-Roman period monitions were experienced, and oracles consulted, as everyone knows. Coming down to recent times, the phenomenon, now fairly common, of intelligent raps, seems to have begun in a family at Hydesville near Rochester, N.Y., about 1848. Stainton Moses, himself a powerful medium, helped to establish the London Spiritualist Alliance, which was joined by the naturalist Alfred Russel Wallace, while the physicist and chemist Sir William Crookes began a series of investigations into a variety of physical phenomena, with the help of the exceptional medium D. D. Home, through whom startling results had been obtained in good-light, as narrated by the late Lord Dunraven (*see* "Experiences with D. D. Home" printed by Maclehose for the S.P.R.).

In the seventies of last century Sir William Barrett made preliminary experiments in thought transference; and Cambridge men of letters began to study the various phenomena seriously. In 1882 a special Society was founded by F. W. H. Myers and Edmund Gurney under the Presidency of Henry Sidgwick. This Society for Psychical Research has accumulated a mass of information, critically examined, recorded and discussed in their *Proceedings*, and the work continues to this day

On the Continent the subject has been taken up by Charles Richet in France, Von Schrenck Notzing in Germany, Morselli, Lombroso and Schiapparelli in Italy, and has been carried on under Dr Geley and his successors in the Institut Metapsychique of Paris and other organizations, while the American Society for Psychical Research has published an extensive collection of records In recent times Professor Charles Richet has written what is virtually a text book of the subject under the title *Traité de Metapsychique*, translated into English as *Thirty Years of Psychical Research* And Dr Geley has discussed the subject from the medical, biological and philosophic points of view in *From the Unconscious to the Conscious* Books containing what purport to be records of communications received through mediums in the trance state are too numerous to mention; but the eloquent work of F W H Myers entitled *Human Personality and its Survival of Bodily Death* not only fairly covers the subject up to 1900, but bids fair to become a classic Selection from other books is difficult A history of the subject in two volumes by Podmore eschews the spiritistic hypothesis in order to emphasize telepathy Another history of the subject emphasizing its religious bearings is by Conan Doyle. Older treatises are Hare's *Experimental Investigations of the Spirit Manifestations* (New York 1856), De Morgan's *From Matter to Spirit* (1863), Alfred Russel Wallace's *Miracles and Modern Spiritualism* (1876), Stainton Moses' *Spirit Teachings*, Zollner's work translated by Massey as *Transcendental Physics* Also *Reports* of the Dialectical Society in London, and of the Seybert Commission in America, and the *Proceedings* of the Society for Psychical Research in 36 volumes

BIBLIOGRAPHY —Books aiming at a philosophical or biological discussion of the subject, in addition to those already mentioned, are — *Supernormal Faculties in Man* by Osty, *Dissociation of Personality* by Morton Prince, *Body and Mind* by McDougall, *Mind and Personality* by William Brown, *Telepathy and Clairvoyance* by Tischner, *Ectoplasm and Clairvoyance* by Geley, *Occultism and Modern Science* by Oesterreich, *The Facts of Psychic Science and Philosophy* by Campbell Holms is an uncritical summary of a large number of asserted observations

Books containing detailed evidence are such as the following — *Phantasms of the Living* (two volumes) by Myers and Gurney (1886), *Evidence for the Supernormal*, by Lloyd Tuckey, *Evidence for a Future Life*, by Delanne, *Psychical and Supernormal Phenomena*, by Joire, *After Death* etc, 3 volumes by Flammarion, *On the Threshold of the Unseen*, by Barrett, and many books by J. Arthur Hill, H. A. Dallas, Drayton Thomas and others (O. J L)

SPITALFIELDS, a district of London, England, in the western part of the metropolitan borough of Stepney. The name is derived from the fact that the land belonged to a priory of St. Mary Spital, founded in 1197.

SPITHEAD, a strait of the English Channel, between the mainland (the coast of Hampshire, England) and the north-eastern coast of the Isle of Wight, forming the eastern entrance to Southampton Water, the Solent being the western It is 12 m long, 4 m wide but between Ryde and Gilkicker Point is almost exactly three miles The Spit Sand, extending south-east from this promontory, gives name to the strait On the north side opens the narrow entry to Portsmouth Harbour, with the towns of Portsmouth and Gosport east and west of it On the south the coast of Wight rises sharply, well wooded, and studded with country residences, and here is the watering-place of Ryde. Spithead shares in the fortifications of Portsmouth Harbour, the principal station of the British navy. The strait has been the scene of many naval pageants

SPITSBERGEN (Norwegian SVALBARD), an Arctic archipelago between Greenland and Novaya Zemlya in 76° 25′ to 80° 50′ N. and 10° 20′ to 35° E, has a total area of 25,000 sq m. and comprises West Spitsbergen (15,200 sq m) North-East Land (about 6,000 sq m), Edge island (2,500 sq m), Barents island (580 sq m.), Prince Charles Foreland, the Wiche islands, Hope island and many smaller islands, including Bear island in about 74° 30′ N 19° E. The archipelago was officially taken possession of by Norway in 1925

Geography.—The chief island is in the main a much dissected plateau with many deep fjords penetrating far inland Small plains are found in the north and west The sharp peaks that gave Spitsbergen its name rise to 4,960 ft in Horn Sund Tind in the south, 3,450 ft in Mt. Monaco on Prince Charles Foreland and 4,770 ft. in Mt. Eidsvoll in the north-west In the middle and east the mountains are flat-topped and seldom over 2,000 ft, but Mt Newton (5,445 ft) in New Friesland is the loftiest peak in Spitsbergen Rocks skirt many stretches of the open coasts but with accurate charting a number of safe harbours have been found Glaciers fill the valleys except in the southern interior where they have receded They generally reach the sea, often along broad fronts, but give rise to no large icebergs Many are in a state of decrepitude, but a few seem to be advancing An ice covering over New Friesland is the nearest approach to an ice sheet in West Spitsbergen Barents and Edge islands have glaciers only on the east The Wiche islands have no large glaciers, but North-East Land and Giles (Gillis) Land are each covered with a dome of ice that almost envelops the island Prince Charles Foreland has numerous glaciers Bear Island with an area of 73 sq m rises to 1,630 ft in Mt Misery The northern part is a plain at an elevation of about 150 feet There are no glaciers Harbours are small and poor. Hope island lies 125 m east of South Cape, Spitsbergen, is 20 m. long and not more than one mile wide It rises to 1,200 feet There is no harbour

Structure and Geology.—The principal features of the geology are known Most formations from early Palaeozoic, and perhaps Archaean, to recent occur The oldest rocks appear chiefly on the west and north, including Prince Charles Foreland and North-East Land They are the Hecla Hook series of Cambrian and Ordovician dolomites, limestones, shales and quartzites which form the Caledonian folds and overthrusts of the west The folds can be traced as far east as the west of North-East Land Granite and gneiss formerly believed to be Archaean probably belong to the same formation and were involved in the Caledonian foldings Some of these crystalline rocks, however, may prove to be pre-Cambrian Outside the area of these old rocks Spitsbergen is mainly a plateau of relatively undisturbed strata lying unconformably on a platform of pre-Devonian crystalline rocks In the north-west there are Devonian rocks These are unconformably overlain by lower Carboniferous or Culm sandstones and shales with some coal Middle Carboniferous is rare and the Culm is generally succeeded by upper Carboniferous limestones, Permo-Carboniferous cherts, and Permian sandstones and shales Next come Triassic, Jurassic and Cretaceous sandstones, limestones and shales In the Cretaceous beds there is coal Unconformably there follow Tertiary sandstones and shales with several coal seams Tertiary folding is obvious in the west against the Hecla Hook beds in places and in the east, but in central Spitsbergen is noticeable only in gentle undulations Heavy faulting occurred in Tertiary times Intrusions of dolerites and basalt were probably of Cretaceous (Neocomian) date An extinct volcano and several hot springs (temp 82° F) in Bock bay are Quaternary The strand flat is well developed at 30–60 ft and post-glacial raised beaches are marked Glacial and post-glacial débris on low ground generally mask the solid rock and loose screes form fans on the lower slopes Bear island is built of Hecla Hook, Devonian and Carboniferous beds The two latter series contain some coal

Climate and Ice Conditions.—The sea around Spitsbergen is shallow, and the ice readily accumulates round the shores Pack-ice prevents access to most shores except for a few months in the year However, the warm North Atlantic drift sends a branch to the western shores of Spitsbergen, moderating its climate, and leaving an open passage which permits vessels to approach the western coast during most months of the year The fjords are frozen from October or November to April or May

Owing to the warm drift the climate of Spitsbergen is less severe than in the corresponding latitudes of Greenland. January and February means range from 0° to −8° F, and July means from 38° to 40° F. Even in the coldest months of the winter a thaw may set in for a few days; but, on the other hand, snow sometimes falls in July and August. Spring comes in June; the snow becomes saturated with water and disappears in places, and scurvy grass and willow open their buds. By the end of June the thermometer has ceased to sink below the freezing-point at night; July, August and September are the best months. In September, however, autumn sets in. The annual precipitation at Green Harbour is 11·6 in. and less in the interior. Winds are generally light except on the west coast and local winds in the fjords. There is mist on the west and around Bear island in summer.

Fauna.—The Greenland whale has disappeared in consequence of the great havoc made by the early whalers. According to Scoresby, no fewer than 57,590 whales were killed between 1669 and 1775. Reckless extermination of seals also took place. Walruses are now rarely seen in the waters of West Spitsbergen. Birds, also, have rapidly diminished in numbers. The fulmar petrel meets ships approaching Spitsbergen far away from the coasts. It makes colonies on the cliffs, as also do the glaucous gull or the "burgomaster." Rotches, black guillemots, ivory gulls, auks, looms and kittiwake gulls breed on the cliffs, while geese, loons and snipe frequent the lagoons and small fresh-water ponds. The eider duck breeds on the islands, but its numbers have become noticeably reduced. These birds, however, are only guests in Spitsbergen, the snowy owl and ptarmigan being the only species which stay permanently. Some 60 species have been recorded from Spitsbergen and Bear island; about half of them breed there. Of land mammals, besides the polar bear, the reindeer and arctic fox have been greatly reduced: Norway has prohibited the slaughter of any reindeer until 1934; before 1868 from 1,500 to 2,000 were killed by hunters in a few weeks of summer.

Vegetation.—The only trees are the polar willow, which does not exceed 2 in. in height and the rare dwarf birch; and the only bushes are the crowberry and cloudberry. But at the foot of the bird cliffs some loam has been formed notwithstanding the slowness of putrefaction, and there, in contrast with the brownish lichens that cover the rocks, grows a carpet of mosses of the brightest green, variegated with the golden-yellow flowers of the ranunculus, the large-leaved scurvy grass, the cuckoo flower, many saxifrages, fox-tail grass, etc.; while on the driest spots yellow poppies, whitlow grasses, and rock roses are found. Even on the higher slopes, 2,500 ft. or more above the sea, the poppy is occasionally met with. In all about 130 species of flowering plants have been found. Although very limited in number, the flora is suggestive in its distribution. Most of the species of flowering plants are found in the flora of Europe while 117 are circumpolar in distribution. Many flowering plants which are common in West Spitsbergen are absent from the east coast, where the cold climate is inimical to both flora and fauna.

Mining.—Coal has been known since the 17th century but was not mined commercially until the 20th century when work began in Advent bay, and progressed slowly there and elsewhere until the development of the coalfields was greatly stimulated during the World War by the scarcity and high price of coal in Scandinavia. The coalmine in Longyear valley, Advent bay, which was under American ownership since 1905, was sold in 1916 to Norwegians. Several other Norwegian mines have started, notably in King's bay and Hjorth Haven in Advent bay and on Bear island (since closed). Swedish mines were worked in Lowe Sound (Braganza bay) from 1917–25. There are Dutch mines in Green Harbour. British enterprise, hampered by war conditions, revived in 1919 in the coal-bearing areas in Klaas Billen bay, Temple bay and Coles bay. By 1920 practically all the coal-bearing areas were annexed by one or other company. In 1927 five mines were exporting coal. The total amount of coal exported in 1925 was 413,000 tons, nearly all of which went to Norwegian ports, including some to Narvik for the Swedish railways. A few thousand tons went to Archangel. The coal exported so far is of Tertiary and Cretaceous ages and proves to be good steam coal. Bituminous coal of Carboniferous age is available but not yet mined. Mining continues throughout the year but the export season at present is from late April to September.

Communications.—There are no regular sailings to and from Spitsbergen but tourist vessels make occasional calls in July and August and many colliers go to and from Norway during summer. There has been a Norwegian radio-station at Green Harbour since 1911 and there are also stations as well as post offices at the chief mines.

Bibliography.—The literature is voluminous. Sir W. Martin Conway in *No Man's Land* (Cambridge, 1906) details the history of Spitsbergen to 1840, tabulates the principal voyages thereafter until 1900, and gives a full bibliography from the earliest time down to 1902. The observations of the Swedish expedition for the measurement of an arc of the meridian were brought together (in French) in *Missions scientifiques pour la mesure d'un arc de méridien au Spitzberg* . . . (Stockholm, 1903–06), and those of the Russian expedition under the same title in 1904, *seq.* (St. Petersburg [Leningrad]). Other important sources of scientific value are the publication of the Swedish *Vetenskaps Akademie; Ymer* (Stockholm); *Videnskaps Akademi* (Oslo), especially the series of papers on *Resultater av de Norske Statsun. Spits. Ekspeditioner* (1922–); Albert I., Prince of Monaco's *Résultats des campagnes scientifiques*, 40, 41 and 45 (1889, etc.); and *Spitsbergen Papers* (Oxford, 1925). Two general works are R. N. Rudmose Brown, *Spitsbergen: its exploration, hunting and mineral riches* (1919) and F. Nansen, *En ferd til Spitsbergen* (1920) or *Spitzbergen* (Leipzig, 1921). G. Isachsen, "Fra Ishavet" in *Det Norske Geografiske Selskabs Aarbok* (1916–19) gives much information about Norwegian hunters. H. M. Cadell, "Coal Mining in Spitsbergen," *Trans. Inst. Min. Eng.*, vol. 60 (1920) and A. Hoel, "The Coal Deposits and Coal Mining of Svalbard" (Oslo, 1925) describe the coal-bearing areas. F. C. Wieder, *The Dutch Discovery and Mapping of Spitsbergen 1596–1829* (Amsterdam, 1919) has many reproductions of early maps. The meteorological observations at Green Harbour are published annually in *Jahrbuch des Norwegischen Meteorologischen Instituts* (Oslo). A. Miethe and H. Hergesell, *Mit Zeppelin nach Spitsbergen* (1911) is noteworthy for the excellence of its illustrations, including colour plates. G. Binney, *With Seaplane and Sledge in the Arctic* (1925), describes recent work in North-East Land. Some of the results of the Norwegian surveys are collected in *Expedition Isachsen au Spitsberg, 1909–10, Resultats scientifiques* (Oslo, 1916). The geomorphology and geology are explained by G. de Geer "On the physiographical evolution of Spitsbergen" *Georg. Annaler*, vol. I. (Stockholm, 1919) and by O. Nordenskjold in *Handbuck der Regionalen Geologie* IV., 2b. (Heidelberg, 1921) with bibliography. *Spitzbergen-Handbuch* (Berlin, 1916) gives full sailing directions. The Spitsbergen Treaty is published in Treaty Series No. 18, Cmd. 2,092 (1924). (R. N. R. B.)

Exploration.—It is probable that Svalbard, discovered by the Vikings in 1194, according to the *Landnamabok*, was Spitsbergen, but the discovery was forgotten. Modern knowledge dates from the discovery by William Barents and Jacob Heemskerk, on June 17, 1596. Barents saw parts of the west and north coasts, and he gave the name of Spitsbergen. In 1607 H. Hudson, after visiting Greenland, reached Spitsbergen and reported whales. Bear island, midway between Spitsbergen and the North cape, had been discovered by Barents, and became important as a hunting-ground (for walrus, etc.), after Stephen Bennet's visit in 1603. In 1609 Thomas Marmaduke reached Spitsbergen, and in the following year the first hunting expedition was despatched thither by the Muscovy company under Jonas Poole, on whose report of the abundance of whales on the coast the Spitsbergen whaling industry was established in 1611. Very shortly the Dutch began to take a share in this, and there were frequent collisions between the whalers of the two nationalities, while in 1615 the Danes attempted to claim this part of "Greenland," as Spitsbergen was for a long time considered. England attempted to annex the archipelago, but at length the Dutch became predominant in the whaling industry, and in 1623 founded the busy summer settlement of Smeerenburg. This began to decline in about 20 years, as the whales were slowly driven from the bays. Marmaduke discovered Hope island and North-East Land in 1613; Edge saw the Wiche islands in 1617; and C. Gillis found Gillis (Giles) Land in 1707. At what period Russians from the White sea district first came to Spitsbergen to hunt walruses, seals, bears, foxes, etc., cannot be known, but the industry had importance before 1740. The Russians called the archipelago Grümant, a corruption of Greenland.

Many expeditions have made Spitsbergen their base for polar exploration. The expedition in the "Racehorse" and "Carcass" sent from England in 1773 under C. J. Phipps, was the first having

a purely geographical purpose. Phipps mapped the north of Spitsbergen and reached 80° 48′ N. In 1818 D. Buchan and J. Franklin reached 80° 34′ to the north of the archipelago. Captain D C. Clavering and Sir Edward Sabine in 1823 explored the islands, and Sabine made his remarkable magnetic observations, while Clavering reached 80° 20′ N. Sir William Parry in 1827 reached 82° 40′ N. of Spitsbergen on sledges In the same year the Norwegian geologist, B. M Keilhau, visited the group The Swede, Sven Loven, was the first to undertake, in 1837, dredging in Spitsbergen waters In 1858 Otto Torell, accompanied by A E Nordenskiold and A. Quennerstadt made important observations and brought home rich geological collections In 1861 a larger expedition led by Torell, Nordenskiold, A J. Malmgren, and K. Chydenius investigated the possibility of measuring an arc of meridian in Spitsbergen The work of the measurement of the arc was completed in 1864 by an expedition led by Nordenskiold, assisted by Malmgren and N. Dunér This expedition was followed in 1868 by that of the "Sofia," under Nordenskiold to the north coast. In the same year the German expedition under K. Koldewey circumnavigated west Spitsbergen In 1870 two young Swedes, Drs A G Nathorst and H Wilander, examined the phosphoric deposits at Cape Thordsen, and two years later a colony was formed and a small tramway constructed to work the beds The attempt, however, did not prove successful Leigh Smith and the Norwegian, Captain E Ulve, visited and mapped parts of east Spitsbergen in 1871, and reached 81° 24′ N In the same year the first tourist steamer visited the archipelago In 1872 an expedition under Nordenskiold wintered in Mossel bay, hoping to set out for the Pole in spring This project had to be abandoned, and Nordenskiold explored North-East Land and crossed the vast ice-sheet which covers it The expedition returned in 1873 In 1882 the Swedish geologists, A G Nathorst and G de Geer, made a journey in Ice Fjord which furnished interesting data about the geology and flora of the islands In the same year a Swedish meteorological station was established at Cape Thordsen for carrying on the observations desired by the international polar committee The expeditions of Gustaf Nordenskiöld in 1890 and the circumnavigation by Nathorst in 1898, during which the Wiche islands and Giles Land were explored, confined their attentions almost entirely to the coasts In 1892 C. Rabot made the first serious attempt to penetrate the interior from the head of Ice fjord, exploring a part of the Sassendal; and in 1896 Sir Martin Conway led an expedition which crossed the island for the first time and surveyed the region between Ice Fjord and Bell Sound In 1897 Conway and E J Garwood surveyed the glaciated area north of Ice Fjord, and climbed Horn Sund Tind In the same year S A Andrée made his fatal balloon ascent from Danes island with the intention of floating over the Pole. In 1896 a weekly service of Norwegian tourist steamers was established in summer, with an inn at Advent bay. In 1898, 1899 and 1906 the prince of Monaco made scientific investigations in the archipelago, and in 1898–1902 Swedish and Russian expeditions undertook the measurement of an arc of the meridian W S Bruce, in 1906–07–09, made a complete survey and scientific investigations of Prince Charles Foreland, and in 1920 J. M Wordie scaled some of its highest peaks, Monaco, Rudmose and Barents In 1910 W. Filchner surveyed the glaciated region between Temple and Mohn bays Every summer since 1906 Norwegian State expeditions, under G Isachsen, A Staxrud and A Hoel, have surveyed in the western side of the mainland, and conducted hydrographic research. King's bay was used by R. Amundsen in his unsuccessful flight to the Pole in 1925, and by him and R. E. Byrd in their successful flights in 1926 G Wilkins alighted in the Fjord in April 1928 after his flight from Alaska (*See* also ARCTIC REGIONS, *Exploration*)

Political History.—The question of political control had been discussed since about 1870, mainly by Norway, Sweden and Russia, without any solution being found Spitsbergen therefore occupied the curious position of being *terra nullius* In 1907, however, Norway again opened negotiations for an international conference to decide the question of sovereignty, and one was held at Oslo (Christiania) in July–Aug 1910, followed by another in 1912, without definite result. In July 1914 a conference which included also representatives of Britain, France, Belgium, the United States, Holland and Germany tried to devise a form of administration consistent with the country remaining a *terra nullius*, but the outbreak of the World War put an end to the discussions In 1919 the Supreme Council conferred on Norway the sovereignty of Spitsbergen, including Bear I and all islands between 10° and 35° E. and between 74° and 81° N The signatories of the treaty were Great Britain and the British Dominions, France, Italy, the United States, Japan, Holland, Denmark, Norway and Sweden Ratifications were delayed and Norwegian sovereignty did not become effective until Aug 1925 Russia has since adhered to the treaty Svalbard is the new name for all islands in the Norwegian sphere in the Arctic, but the names of individual islands are unchanged Svalbard is deemed a part of the kingdom of Norway and is administered by a governor (*sysselmann*) and a small staff Game laws have been made. (X, R N R B)

SPITTA, JULIUS AUGUST PHILLIP (1841–1894), German writer on music, was born at Wechold, Hanover, on Dec 27, 1841. He was one of the founders of the Bachverein at Leipzig in 1874 In 1875 he became professor of musical history at the university of Berlin, and at the conservatoire, of which in 1882, he became a director His *J S. Bach* (2 vols Leipzig, 1873–80, Eng trans, 3 vols, 1884–5), is one of the great classic musical biographies Spitta, who was one of the editors of the *Vierteljahrsschrift für Musikwissenschaft* from 1885 onwards, died in Berlin on April 13, 1894 His other works include editions of the organ works of Buxtehude (2 vols, Leipzig, 1874–6), and of the works of Heinrich Schutz

SPITTELER, CARL (1845–1924), Swiss poet and novelist, was born at Liestal, near Basle, April 24, 1845, and died at Lucerne Dec 28, 1924 In youth he studied theology, but did not pursue a clerical career After many years of teaching (eight of them in Russia), he published his first important work, *Prometheus and Epimetheus*, in 1880–81, under the pseudonym of "Felix Tandem" This was an epic, written in a rhythmical, quasi-biblical, hieratic prose A little later appeared *Extramundana* (1883), a volume of apologues in verse From 1885 to 1892 he engaged in journalism, but published *Schmetterlinge* (1889), a series of short poems After 1892, when he settled in Lucerne, he was able to devote himself wholly to literature Three other volumes of short poems were produced between 1892 and 1906—*Literarische Gleichnisse, Balladen* and *Glockenlieder* In 1900–05 appeared his long epic, *Olympischer Frühling*, which was cited as the main ground for the award of the Nobel Prize for literature in 1919 His prose writings include *Imago* (1906) and three other romances, *Lachende Wahrheiten*, a volume of essays (1898; Eng trans 1927); *Die Madchenfeinde* (1907; Eng trans, 1922), a story founded on a reminiscence of his boyhood; and *Meine frühesten Erlebnisse* (1914), a charming account of his childhood. His last work published in 1924, shortly before his death, was *Prometheus der Dulder*, a metrical, compacter and maturer treatment of the theme of *Prometheus and Epimetheus*.

Robertson in the *Contemporary Review* (Jan 1921). *See* also the introductions to the translations of *Lachende Wahrheiten* (Laughing Truths; 1927) and *Selected Poems* (1928) (J F M)

SPLEEN, a vascular organ situated on the left side of the abdomen (*see* DUCTLESS GLANDS)

SPLIT or **SPLJET** the capital of Dalmatia, Yugoslavia (Ital *Spalato*), has the finest harbour on the Adriatic coast, with a broad bay affording deep, safe anchorage This, combined with its central position, and good communication with other parts by road, rail and steamer, has made it of great commercial importance, with an extensive trade in wine and oil Pop (1921) 25,042, almost entirely Serbo-Croatian Spalato arose from the palace of Diocletian, who renounced the imperial crown in A D 303 and lived here until his death The palace was then allowed to fall into ruin, but when the incursion of the Avars was over (639) the inhabitants of the ruined city of Salona, near by, took refuge here, and built up

homes within the 9½ acres covered by the palace, incorporating its walls and pillars. Its ground plan is like a Roman camp, *i.e.*, almost a square with four quadrangular towers and four gates, with four streets meeting in the middle. The eastern gate, or Porta Aenea, is destroyed, but the western gate, or Porta Ferrea, and the main entrance to the building, the beautiful Porta Aurea, are still in fairly good preservation. The streets are lined with massive arcades. The vestibule now forms the Piazza del Duomo or cathedral square; to the north-east of this lies the temple of Jupiter, or perhaps the mausoleum. Since the 9th century this has been the cathedral of St. Doimo or Domnius, noteworthy for its finely carved choir stalls. To the south-east is the temple of Aesculapius, long transformed into a baptistery, a beautiful Romanesque campanile having been added in the 14th and 15th centuries.

Excavations have been carried on intermittently at the ruins of Salona, 4 m. north-east, since 1818, and many interesting architectural remains have been discovered together with many smaller relics, now housed in the Split Museum. These include prehistoric objects. Salona was made a Roman colony in 78 B.C. and was one of the chief ports of the Adriatic. Soon after 313 the city became an episcopal see with St. Doimo as its first bishop. The palace was transformed into an imperial cloth factory. The town was captured several times by the Goths and Huns and in 639 was destroyed by the Avars, but was not entirely deserted until the end of the 12th century. In 659 John of Ravenna, the papal legate, was created bishop of Spalato, as the new city was called, the origin of the name being uncertain. A little later it became an archbishopric, and its holders were metropolitans of all Dalmatia until 1033. In 1105 Spalato became a vassal state of Hungary; in 1327 it revolted to Venice, but in 1367 returned to Hungary. It was ruled by the Bosnian king Tvrtko from 1390 to 1391, and in 1402 by the famous Bosnian prince Hrvoje. A large octagonal tower is still known as *Torre d'Harvoye.* In 1420 Spalato fell to Venice and ceased to have an independent history. The castle and walls were erected by the Venetians between 1645 and 1670 and dismantled during the French occupation of Dalmatia (1805–13) in which latter year the province returned to Austria, who still held it at the outbreak of the World War (1914–18). Owing to this fact, the Croatian inhabitants suffered greatly, their intelligentsia being deported in chains as hostages, while the occupation of the town by the Italians in 1918, led to still further hardships.

Lavallée, *Voyage pittoresque et Historique de l'Istrie* (Paris, 1802) illustrated; and G. Lucio, *De Regno Dalmatiae et Croatiae* (Amsterdam, 1666) for chronicles relating to Spalato and Salona.

SPLÜGEN PASS, one of the passes across the main chain of the Alps from Switzerland to Italy. The route from Thusis passes first through the celebrated gorge of the Via Mala, then through the Schams basin and past Andeer, beyond which the Rofna gorge gives access to the village of Splügen in the upper reach of the main or Hinter branch of the Rhine (*q.v.*). Leaving to the west the road over the San Bernardino Pass, 6,769 ft., the Splügen road (constructed in 1823) mounts south to the pass (6,946 ft.), which forms the political frontier. On the other side the road avoids the old path through the dreaded Cardinello gorge (here passed Macdonald's army in December, 1800) in order to descend by zigzags to Pianazzo. Thence past Campo Dolcino and Gallivaggio the descent is made to the ancient town of Chiavenna at the junction of the road from the upper Engadine over the Maloja Pass, and 17 m. by rail above Colico, at the northern end of the lake of Como. The distance by road from Splügen village (16 m. above Andeer) to Chiavenna is 25 m.

SPODUMENE, a lithium-aluminium silicate ($LiAl[SiO_3]_2$) belonging to the pyroxene group (*see* PYROXENE), named in 1800 from Gr. σπόδιος (ash-coloured), in allusion to its colour, and soon afterwards termed by J. R. Haüy *triphane* (τριφανής, appearing three-fold), because it exhibited certain characteristics equally in three directions. Spodumene crystallizes in the monoclinic system, the crystals having generally a prismatic habit and being often striated longitudinally. It has perfect prismatic cleavage, and imperfect cleavage parallel to the clinopinacoid, whilst a lamellar structure may be developed by parting along the orthopinacoid. The hardness is 6·5 to 7, and the sp.gr. about 3·16. Though generally a dull mineral, some varieties of spodumene are so brightly coloured and transparent as to be valued as gem-stones, *e.g.*, the emerald-green hiddenite (*q.v.*) and the lilac-coloured kunzite (*q.v.*), whilst a yellow or yellowish-green spodumene found as pebbles in the state of Minas Geraes, Brazil, resembles, when cut, some kinds of chrysoberyl. Common spodumene is used as a source of lithium in chemical preparations.

Spodumene occurs in granite and crystalline schists. The original specimens came from the isle of Utö, Sweden, but the finest examples are found in the United States, especially in Massachusetts, fine specimens having also been obtained from the Black Hills of S. Dakota. Some remarkable deposits containing spodumene were discovered many years ago at Branchville, Connecticut, and were exhaustively studied by G. J. Brush and E. S. Dana. The spodumene occurred in large quantity, in a vein of albite-granite, associated with apatite, garnet, columbite, pitchblende and other uranium minerals, with several manganese phosphates.

SPOFFORTH, FREDERICK ROBERT, "The Demon" (1853–1926), Australian cricketer, was born at Sydney, N.S.W., on Sept. 9, 1853, and died at Surbiton, Surrey, on June 4, 1926. He was educated at Eglington college, Sydney, and played in Australia up till 1888, when he came to England, and played occasionally in England until 1896. He visited England in the five tours from 1878 to 1886, and in his two great years, 1882 and 1884, took 188 and 218 wickets. Little interest was taken in England in the first Australian tour of 1878 up to his appearance, at Lord's, to play the M.C.C. on May 27. By the end of the day the match was over; the M.C.C. were put out for 33 and 19, and Spofforth had taken 6 wickets for 4 runs and 4 for 16. This one day established Australia as a first-class cricketing power. His other great triumph was during the historic tour of 1882. In the test match at the Oval, England, with 84 to make to win, he lost by 7 runs. In the match Spofforth took 14 wickets for 90 runs. He was badly hurt early in the 1886 tour, and was never the same bowler again.

Of Spofforth's actual pace there are differing opinions. It is perhaps, safe to say that when he first came to England he was really fast, but it is certain that he learnt at once to modify his pace on English wickets, and relied on disguised change of pace, with perhaps one really fast one in an over. Of his supremacy there is no doubt whatever. It may suffice to quote Lord Harris: "Spofforth was the most difficult of them all." Spofforth was above all a man who "bowled with his head"; he got his wickets by variation of pace and flight, combined with a sharp off-break, and maintained an ascendancy by an unquenchable spirit of aggression, displayed in his terrifying run up to the wicket, with his long arms whirling, finishing in a beautifully graceful delivery which made the most of his great height.

Spofforth's bowling is fully illustrated in Beldam and Fry's *Great Bowlers and Fielders* (1907). *See* also *Scores and Biographies* (vol. xiv.); Reminiscences in Wisden's *Cricketers' Almanack* for 1927; H. S. Altham, *History of Cricket* (1925).

SPOHR, LUDWIG (1784–1859), German composer and violinist, was born at Brunswick on April 24, 1784. He spent his childhood at Seesen, where in 1789 he began to study the violin, and at six years old was able to take part in chamber-music. He had a few lessons in composition, but, as he himself tells us, he learnt more from studying the scores of Mozart. After playing a concerto of his own at a school concert with marked success, he was placed under Maucourt, the leader of the duke's band; and in 1798 he started on an artistic tour. He made his way to Hamburg, but had to return on foot. The duke then gave him an appointment in his band, and provided for his future education under Franz Eck, with whom he visited St. Petersburg and other European capitals. His first violin concerto was printed in 1803. In 1805 he became violinist to the duke of Gotha. Soon

after this he married, his first wife being Dorette Scheidler, a celebrated harpist.

At Gotha Spohr composed his first opera, *Die Prufung*, but did not succeed in producing it *Alruna* was equally unfortunate, though Goethe approved of it at a trial rehearsal at Weimar in 1808. In this year Spohr, hearing that Talma was performing at Erfurt before Napoleon's Congress of Princes, and failing to obtain admission to the theatre, bribed a horn-player to send him as his deputy; and, though he had never touched a horn in his life, he learned in a single day to play it well enough to pass muster in the evening and to get a good view of Napoleon and the princes in a pocket mirror on his desk Spohr's third opera, *Der Zweikampf mit der Geliebten*, written in 1809, was successfully performed at Hamburg next year In 1811 he produced his (first) *Symphony in E flat*, and in 1812 composed his first oratorio, *Das jungste Gericht*[1].

· In 1812 Spohr became leader of the orchestra at the Theater an der Wien, Vienna He then began his dramatic masterpiece, *Faust*, which he completed in 1813, though it was not performed until five years later He resigned his appointment at Vienna in 1815, and made a tour in Italy, where he performed his eighth and finest violin concerto, the *Scena cantante nello stilo drammatico* The leading Italian critics called him "the finest singer on the violin that had ever been heard" On Spohr's return to Germany in 1817 he was appointed conductor of the opera at Frankfort, and there in 1818 he first produced his *Faust* It was followed by *Zemire und Azor*, which, though by no means as fine as *Faust*, soon attained a much greater popularity. *Faust* suffered from its libretto, which is on quite a different plot from Goethe's poem

Spohr first visited England in 1820, and on the 6th of March played his *Scena cantante* with great success in London at the first Philharmonic concert At the third he produced a new symphony (*No 2 in D minor*) and, instead of having it led by the first violinist and a *maestro al cembalo*, conducted it himself with a bâton, a great innovation in London at the time After a visit to Paris, and a short sojourn in Dresden, Weber recommended him strongly to the elector of Hesse-Cassel as Kapellmeister Spohr began his duties at Cassel on Jan 1, 1822, and produced his sixth opera, *Jessonda*, in 1823

In 1822 Mendelssohn, then a boy of thirteen, visited Cassel; a firm friendship sprang up between the two, which ceased only with Mendelssohn's death in 1847. Spohr's next three operas, *Der Berggeist* (1825), *Pietro von Abano* (1827) and *Der Alchymist* (1830), attained only temporary success. At the Rhenish musical festival held at Dusseldorf in 1826, his oratorio *Die letzten Dinge* (*The Last Judgment*), the most famous of his sacred compositions, was produced In 1831 Spohr published his admirable *Violin School* The year 1834 was saddened by his wife's death Two years later he married a pianist, Marianne Pfeiffer During 1833 he had been working at an oratorio—*Des Heilands letzte Stunden* (*Calvary* or *The Crucifixion*), which was performed at Cassel on Good Friday 1835, and sung in English at the Norwich Festival of 1839 under Spohr's own direction, with an effect which he afterwards always spoke of as the greatest triumph of his life For the Norwich Festival of 1842 he composed *The Fall of Babylon*, which also was a perfect success, though the elector of Hesse-Cassel refused Spohr leave of absence to conduct it His last opera, *Die Kreuzfahrer*, was produced at Cassel in 1845 Of his nine symphonies the finest, *Die Weihe der Töne*, was produced in 1832.

Spohr's compositions for the violin include concertos, quartets, duets and other concerted pieces and solos, and among these a high place is taken by four double quartets (*i e*, octets for two antiphonal string-quartet groups), an art-form of his own invention. He was, indeed, keenly interested in experiments, notwithstanding his attachment to classical form; and the care with which he produced Wagner's *Fliegender Holländer* and *Tannhäuser* at Cassel in 1842 and 1853, in spite of the elector's opposition, shows that his failure to understand Beethoven lay deeper than pedantry He died at Cassel on Oct 16, 1859

[1]Not to be confused with *The Last Judgment.*

See his *Selbstbiographie* (Eng trans, 1865); and *Letters of a Leipzig Cantor*, ed A D Coleridge (1892)

SPOKANE (spō-kăn′), a city of eastern Washington, U S A, at the falls of the Spokane river, 50 m from its mouth in the Columbia river; a port of entry and the county seat of Spokane county It has a municipal airport, is on Federal highways 10, 95, 195 and 395, and is served by the Chicago, Milwaukee, St Paul and Pacific, the Great Northern, the Northern Pacific, the Spokane International, the Spokane, Portland and Seattle and the Union Pacific railways, and by numerous electric trolley and motor-coach lines Pop (1920) was 104,437 (83% native white); (1928 local estimate) 126,000 Spokane is the metropolis of the "Inland Empire" of 200,000 sq m, lying between the Rocky mountains on the east and the Cascade or Coast range on the west, and embracing eastern Washington, north-eastern Oregon, northern Idaho, western Montana and southern British Columbia The city has an area of 40 37 sq m and an altitude of 1,891 ft, and is surrounded by pine-clad mountains, rivers, cascades, waterfalls, lakes (76 within 50 m), orchards and fertile fields of grain It is protected by the mountain ranges from extremes of heat and cold and from the fogs of the coast The average year has 208 days of sunshine, 16 5 in of rainfall, and a "growing season" of 183 days between killing frosts Through the city, in the heart of the business section, flows the Spokane river, tumbling over cataracts, from which 25,000 h p of electric energy is generated The city is clean and well built, with substantial business buildings and commodious hotels; well paved, well lighted, and well kept streets; and delightful views in every direction Since 1911 it has been under a commission form of government The park system includes in all 2,200 acres. Mount Spokane (5 808 ft high), 35 m N E, is maintained by the State as a public recreation ground Three miles west of the city is Ft George Wright, an important post of the U S army, in a reservation of 1,022 ac, presented to the Government by the city in 1894 The assessed valuation of property in 1926 was $85,981,102

Schools.—The investment in public-school buildings and equipment amounts to over $7,000,000, and the teaching staff in 1928 numbered 760 Gonzaga University (Roman Catholic; opened 1887), Whitworth college (Presbyterian; founded in Tacoma in 1890) and Spokane college (Lutheran) are in the city

Resources and Commerce.—The Inland Empire is rich in natural resources (lumber, minerals, fertile soil and water power) and Spokane is its principal market, supply point, manufacturing and distributing centre and financial capital The wholesale and jobbing business of the city is estimated at $225,000,000 annually Spokane is fairly entitled to the sobriquet "the power city," for by 1928 the hydro-electric plants of the district developed 278,943 h p, of which 187,300 h p was generated by the seven plants on the Spokane river in and near the city This electric power operates mines, maintains extensive irrigation projects, runs transcontinental trains over the Rockies and the Cascades, and supplies current for industrial plants, street-cars and suburban trains, street lamps, domestic lighting and the household appliances which are widely used Spokane has a branch of the Federal Reserve Bank at San Francisco and of the Federal Land Bank

History.—The first permanent settlement on the site of Spokane was made in 1874 by James N Glover, who bought a tract of land from two trappers The town was incorporated in 1881, as Spokane Falls, received a city charter later in the year, and became the county seat in 1882 In 1890 "Falls" was dropped from the name Spokan (said to mean "children of the sun") was the name of an Indian tribe of Salishan stock which had formerly occupied the river valley The Northern Pacific railroad reached the city in 1883, the Union Pacific in 1889, and the Great Northern in 1892 In 1889 (Aug 4–6) a fire destroyed 30 blocks in the heart of the city, practically the entire business section, at a loss estimated at $5,000,000, but within two years the district was rebuilt, with great improvements The population was 19,922 in 1890, 36,848 in 1900 and 104,402 in 1910. The pioneer who laid out the town site lived to see a city of over 100 000

SPOLETO (anc. *Spoletium*), a town and archiepiscopal see of the province of Perugia, Italy, 18 m N N E of Terni, and 88 m.

N. by E. of Rome by rail. Pop. (1921) 17,678 (town); 28,289 (commune). It is situated on a hill, so that the lowest part is about 1,000, the highest 1,485 ft. above sea-level, at the south end of the open valley of the Topino, a tributary of the Tiber, which it joins near Assisi. The principal industries are the collection and preparation of truffles and preserved foods, also tanning and the manufacture of earthenware, cotton and wool spinning. Spoleto is also the centre of an agricultural district, and contains a government experimental olive oil factory. There are few towns of Italy which possess so many Roman remains in good preservation under the medieval buildings, and few medieval towns with so picturesque an appearance. There are considerable remains of pre-Roman polygonal walls. There are remains of a Roman theatre, over 370 ft. in diameter, and an amphitheatre 390 by 295 ft. A Roman bridge of three arches, 80 ft. long and 26 ft. high, exists at the lower (north) entrance to the town.

The rock above the town was included within the polygonal walls: but Totila fortified, not this rock, but the amphitheatre, which remained the citadel until 1364, when Cardinal Albornoz destroyed it and erected the present Rocca, which was enlarged by Pope Nicholas V.; it is now a prison. The Porta Fuga (the name alludes to the repulse of Hannibal) occupies the site of a Roman gate, but is itself medieval: while the medieval enceinte encloses a somewhat wider area than the ancient. The Piazza del Mercato represents the Roman forum; close by is a triumphal arch of Drusus and Germanicus (A.D. 21), and a temple (?) over which is built the church of S. Ansano. A Roman house in the upper part of the town, with mosaic pavements, probably belonged to Vespasia Polla, the mother of the emperor Vespasian. The Palazzo Municipale, above it, contains the archives and picture gallery. The cathedral of S. Maria Assunta, much modernized in 1634 by Bernini, occupies the site of a church of the Lombard dukes erected about 602. The present church was consecrated in 1198; the façade with eight rose windows belongs to the middle of the 12th century. Over the main entrance is a large mosaic of Christ enthroned, with the Virgin and St. John, by the artist Solsernus (1207). The Early Renaissance vestibule (after 1491) is fine. In the choir and on the half dome of the apse, are the finest frescoes of Fra Filippo Lippi (scenes from the life of the Virgin) completed after his death by Fra Diamante: his tomb, erected by Lorenzo de' Medici, with the epitaph by Politian, is on the left of the choir. The fine stalls and panelling in the winter choir date from 1548–54. The Campanile is beautiful.

The church of S. Pietro, outside the town, has a façade richly sculptured with grotesque figures and beasts, of two different dates, about 1000 and about 1200. The little church of SS. Giovanni e Paolo (12th century) contains frescoes of the 12th–14th centuries notably an early representation of the martyrdom of S. Thomas à Becket and a portrait of S. Francis of Assisi. S. Domenico is a fine example of later Italian Gothic with bands of different coloured stone. Both the church and its crypt contain 14th century frescoes. The triple-apsed crypt of S. Gregorio probably dates from the 9th century; the upper church was consecrated in 1146 and the Romanesque work covered with stucco in the restoration of 1744. S. Nicolò is a beautiful example of Pointed Gothic. The basilica of S. Salvatore (*il Crocefisso*) at the cemetery belongs to the 4th century A.D. The fine sculptures of the façade, with its beautiful windows, as also the octagonal dome, all belong to this period. It was restored in 1815. S. Ponziano, not far off, belongs to the 13th century. The city is still supplied with water by an aqueduct, to which belongs the huge bridge called the Ponte delle Torri, crossing the ravine which divides the town from the Monte Luco (2,723 ft.). The bridge is 253 ft. high and 755 ft. long and has ten arches: it was erected in 1364.

After the battle of Trasimenus (217 B.C.) Spoletium was attacked by Hannibal, who was repulsed. It suffered greatly during the civil wars. Sulla, after his victory over Crassus, confiscated the territory of Spoletium (82 B.C.). Under the empire it again became a flourishing town. It was situated on a branch of the Via Flaminia, which left the main road at Narnia and rejoined it at Forum Flaminii. An ancient road also ran hence to Nursia. Martial speaks of its wine. Aemilianus, who had been proclaimed emperor by his soldiers in Moesia, was slain by them here on his way to Rome (A.D. 253), after a reign of three or four months. The foundation of the episcopal see dates from the 4th century. Owing to its elevated position it was an important stronghold during the Vandal and Gothic wars. It was beautified by Theodoric (493) and fortified by Belisarius (536) but its walls were dismantled by Totila (546). Under the Lombards Spoleto became the capital of an independent duchy (from 570), and its dukes ruled a considerable part of central Italy. Together with other fiefs, it was bequeathed to Pope Gregory VII. by the empress Matilda, but for some time struggled to maintain its independence. In 1155 it was destroyed by Frederick Barbarossa. In 1213 it was definitely occupied by Gregory IX. During the absence of the papal court in Avignon it was a prey to the struggles between Guelphs and Ghibellines, until in 1354 Cardinal Albornoz brought it once more under the authority of the Church. In 1809 it became capital of the French department of Trasimene. In 1860 it was taken by the Italian troops after a gallant defence.

At Monteleone di Spoleto a circular tumulus was found in 1902, with a rectangular chamber in the centre, and in it was the famous *biga* (two horse chariot), the only ancient one found in a complete state, which is now in the Metropolitan Museum at New York. (T. A.)

SPONGES. Mediterranean civilisation has used sponges from the earliest times. Homer describes Hephaestus as washing off the grime of the smithy with a sponge (Iliad, xviii., 414), while the household servants of Penelope and Odysseus used sponges to swab down the tables in the dining-hall (Odyssey i., 111; xxii., 22, 439). Aristotle calls the kind of sponge used for padding helmets and greaves *Achilleion,* and says it was "very fine, very dense, and very strong"; this was probably the "Elephant's Ear" sponge. The Romans made paint-brushes of "Achilleum" (Pliny), and used sponges on wooden handles for mops. The Gospels (Mark xv., 36) show that a sponge was a common article in Roman Jerusalem.

Commercial Sponges.—Modern trade recognises five principal kinds of sponges from the Mediterranean—(1) The Fine Turkey Cup (*Euspongia officinalis mollissima*), is softest and most delicate, but little more so than (2) the Fine Turkey Solid (*E. officinalis adriatica*), the soft bath-sponge, cushion-shaped and larger than the cup-sponge. (3) The Zimocca, Brown Turkey or Hard Greek sponge—"fine dure" of the French—(*Euspongia zimocca*) is a hard sponge, usually a cup-shape flattened almost to a disc; its harsh surface makes it useful for scrubbing. (4) The Elephant's Ear (*Euspongia officinalis lamella*) is a thin-walled shallow cup whose shape and elasticity gives it special value for stuffing, its texture and flatness for polishing. (5) The Honeycomb (*Hippospongia equina*) is the well-known Mediterranean bath-sponge (French "Venise"); its large size, uniform fibre, and many wide cavities distinguish it from the Turkey Solid, while the comparatively continuous skin between the round holes on the upper surface distinguish it from the bath-sponges now obtained from the west Atlantic.

FROM LENDENFELD, "HORNY SPONGES," BY COURTESY OF THE COUNCIL OF SOCIETY

FIG. 1.—SKELETON OF BUSH HORNY SPONGE (DENDRILLA ROSEA)

In sponges from the shallow seas near the Bahamas and Florida the round holes are usually each bordered by a pronounced circular ridge or fringe; often each is on the top of a "tower" or finger (noticeably in the Reef Sponge or [6] Glove Sponge, *Euspongia tubulifera*); possibly this protection of the vent-hole is because there is more sediment in the water. It may be for the same reason that we find in this American sea no cup-sponges or toadstool shapes. The fibre is more brittle than in sponges from Levantine waters, possibly because of suspended lime in the

water; but it must also be remembered that the water-temperature at the Bahamas is about 27° C against 17° C. in the Mediterranean Compared with the Mediterranean, the Caribbean sponges show more numerous tassels and brushes on the upper surface, especially in (7) the Wool Sponge (*Hippospongia gossypina*), with surface resembling a lamb's fleece, the staple "bath-sponge" of these fisheries. The surface is characterized by grooves and deep channels between the tufts, because the skin in life has less, or

FIG 2 —COMMON SPONGES OF TEMPERATE SEAS

A Branched Finger Sponge (*Chalina oculata*); B. Sea Fig (*Suberites ficus*), C Tow Sponge (*Vibulinus stuposus*); D *Axinella dissimilis*; E. Common Sponge (*Leucandra fistulosa*); F. Sea Sponge (*Donatia lyncurium*); G Mermaid's Glove (*Desmacidon fruticosum*); H. Brittle Horny Sponge (*Spongelia fragilis*)

less resistant, skeleton than in the Mediterranean; consequently water-passages which were in life roofed with skin are open in the cleaned skeleton, the tufts being the columns which supported the skin (8) The Velvet Sponge (*Hippospongia maeandriformis*) shows these grooves very markedly, it comes nearest in softness to the Turkey Sponges (9) The Hard-head or Honeycomb Reef Sponge (*Euspongia agaricina*) and (10) the hairy Yellow Sponge (*Euspongia corlosia*) are hard when squeezed, approaching the character of the Zimocca (11) The Grass Sponges (*Hippospongia graminea* and *H cerebriformis*) are the least valuable commercially, they have the form of a truncated cone fluted with deep furrows Roughly, one third of a pound's weight of Turkey Cup sells for about as much as a pound of Mediterranean Honeycomb or Wool Sponge, as three pounds of Velvet or Yellow Sponge, or as ten pounds of Grass or Glove The lagoons of Bermuda grow a hard sponge (*Hippospongia lapidescens turrita*) with kiln-like towers, which is only suitable for rough purposes

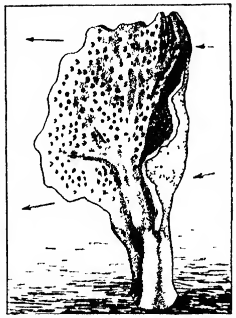
Australian waters have a number of undoubtedly valuable sponges; fine bath-sponges occur in Torres Straits, on the west coast, and near Port Phillip In the South Caroline Islands they fish and use (12) a fine soft sponge (*Coscinoderma lanuginosum*) much resembling the Turkey Sponge in character, the same sponge occurs near Port Phillip The Great Barrier Reef Expedition is at present (October, 1928) re-investigating the Australian toilet sponges and the results seem promising (June 1929)

In all these cases the "sponge" is the cleaned skeleton of a creature that lives attached to the sea bottom The skeleton is formed of *spongin*—a substance resembling silk (*q v.*) in chemical character and composition, and, like silk, belonging to the "scleroproteins" (of which horn is another familiar example), a group of highly insoluble nitrogenous substances, apparently easily formed as waste-products from the life of protoplasm

Sponges with a skeleton of spongin are known as Horny Sponges (*Ceratosa*), and include many other species besides the dozen used by man There are two main groups: those with latticed or netted skeletons (*Dictyoceratida*) like the market-sponges, and those with tree-like skeletons (*Dendroceratida*) The tree-like skeletons grow up from the basal spongin plate; the netted skeletons grow in from any part of the semi-solidified, sticky spongin cuticle (fig 1).

Of other sponges—wholly useless to man—there are many thousands of species. The skeleton usually contains crystalline spicules; these are of cubic opal (silicic acid with cubic symmetry) in the Glass Sponges, of cubic opal, cemented by varying quantities of spongin, the Needle-sponges, of tetrahedral opal in the Four-ray Sponges, and of carbonate of lime, in the form of calcite (Iceland spar), in the Chalky Sponges Siliceous spicules of fossil sponges have formed our flints.

Characteristics and Relationships.—Spicules or spongin-fibres are in the living sponge all surrounded by the living substance which has formed them, except that often some spicules are pushed outwards by their own growth until they bristle the surface. Sometimes they are pushed out by their growth—to form a stalk for the sponge (*Hyalonema*—Glass-rope sponge) or a beard rooting it in the mud (*Euplectella*, fig 9).



AFTER BIDDER IN QUAR JOUR MICROSCOP SC

FIG 3 —FAN SPONGE (PHAKELLIA CONULOSA) IN UNCHANGING OCEAN CURRENT, WATER ENTERING BY PORES ON ONE SIDE AND LEAVING BY VENTS ON THE OTHER

A microscopic examination shows that the living substance is composed of protoplasmic cells, which, in all groups except the Glass Sponges, surround and penetrate a clear glutinous semi-fluid *intercellular jelly* Throughout the many forms there are always some tubes or cavities in the sponge lined with *flagellate cells* each bearing a fine whip (Latin *flagellum*) with which they lash on the water so that it keeps moving through the cavities and bringing fresh food for the sponge These are also called *collar-cells*, because there is a little collar (fig 6) surrounding the butt of the flagellum and so preventing its side-to-side movements from knocking away particles of food from the cell, it also acts as a valve to prevent water flowing the wrong way

Precisely similar collar-cells are to be seen in the Collar-flagellates or *Choanoflagellata* (a group of Protozoa, *q v*), and it seems certain that the Horny Sponges and their relations have

FIG 4 —COMMON SPONGES OF TEMPERATE SHORES

A Colony of Bead Sponge (*Halichondria*); B Chimney Sponge (*Leucosolenia variabilis*); C. Cockscomb (*Hymeniacidon*); D Lace Sponge (*Clathrina coriacea*); E. Sack Sponge (*Grantia compressa*); F. Coronet Sponge (*Sycon ciliatum*)

originated from protozoan Collar-flagellates which have taken to sticking together into colonies, and then to secreting so much adhesive substance that it forms a jelly continuous under the bases of the cells (fig 7) from which rations can be drawn by cells who are not themselves catching any food Socialism and class-distinction are thus alike established, and sponges have therefore passed out of the grade of Protozoa, where cells are typically separate, similar and individualist The title of Metazoa has been given to the further-developed animals with stomachs (*Enterozoa*); W J Sollas has therefore called the sponges *Parazoa*

The Glass Sponges have probably emerged to the rank of Parazoa by another route from other Collar-flagellates. Their cells rarely form any intercellular jelly, but for the most part lie naked in the water as a branching network or cobweb (fig. 9). Opposed to the "True" gelatinous sponges, we may call these "Naked sponges."

CLASSIFICATION

Sub-kingdom PARAZOA Sollas—*Porifera* Grant. Sponges.

Colonial Collar-flagellates consisting of cells of more than one kind.

Phylum 1. NUDA. Naked Sponges. Originating from branching colonies of naked cells.

Class 1 and Order 1. *Hexactinellida.* Glass Sponges.

Phylum 2. GELATINOSA. True sponges. Originating from adhesive colonies of cells bedded in secreted jelly.

Class 2 and Order 2. *Monaxonellida.* Needle-sponges[1].
  Families: Clavulidae (Pin-cushions); Desmacidonidae (Claw-sponges); Axinellidae (Fans); Renieridae (Spindle-sponges).

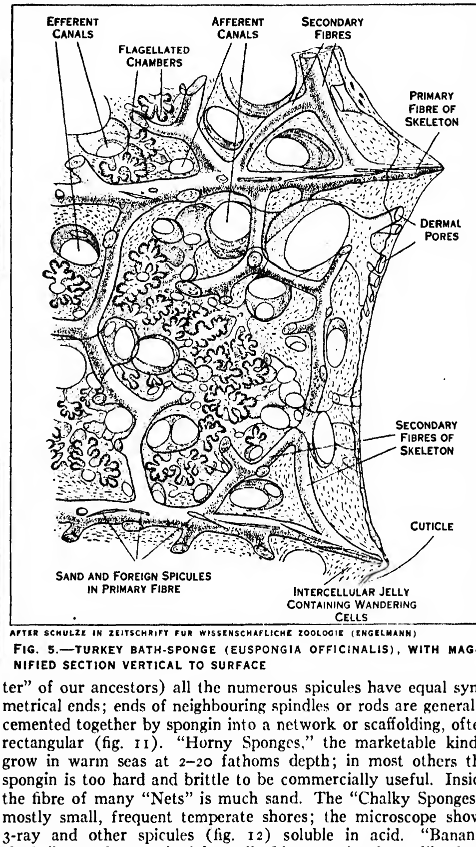
Class 3. *Ceratosa.* Horny Sponges.
  Order 3. Dendroceratida (Horny Bushes).
  4. Dictyoceratida (Horny Nets).

Class 4. *Calcarea.* Chalky Sponges.
  Order 5. Calcaronea (Banana-chalks).
  6. Calcinea (Lace-chalks).

Class 5. *Tetraxonida* (s.s.) Four-ray Sponges.
  Order 7. Plakinida (Flat Four-rays).
  8. Tetractinellida (Grapnel-sponges).
  9. Donatiida (Plane-fruits).
  [10. Lithistida (Stony Sponges). Not a true group.]

This classification represents the opinions of the writer; others will be found in the text-books. Vosmaer (13), Sollas (2), Delage (5) and Dendy separated *Calcarea* from all other sponges. Dendy included all Needle-sponges in *Tetraxonida.* Hentschel (4) in the Phylum and Class *Porifera* recognises five equal Orders; Pin-cushions are placed in *Tetraxonida,* the other Needle-sponges are united with Horny Nets in *Cornacuspongida* and the Horny Bushes form the 5th Order, *Dendroceratida.* Emile Topsent in 1928 (17) divides the *Porifera* into three Classes: *Calcaria* (=Chalks), *Triaxonia* (=Glass-sponges), and *Demospongiaria* to include the rest. *Demospongiaria* contain the Sub-classes *Tetractinellida, Monaxonellida,* and *Ceratellida* (=Horny Sponges). *Tetraxonellida* are the Four-rays without the Plane-fruits and Gristly sponges: these are included in *Monaxonellida* (Needle-sponges), and united with Pin-cushions to form the Order *Hadromerina. Monaxonellida* have four Orders: *Hadromerina; Halichondrina* (=Fans); *Poecilosclerina* (=Claw-sponges); *Haplosclerina* (=Spindle-sponges). The figures (except dates) in parentheses following authors' names in the foregoing and subsequent paragraphs refer to works so numbered in the *Bibliography* at the end of this article.

The "Glass Sponges" are exclusively deep-sea sponges, with large spicules, often extended into long threads like delicately spun glass (fig. 9), but typically four-rayed or six-rayed rectangular crosses with one or more rays often exaggerated or suppressed. The "Needle-sponges," with spicules generally like needles, rods, or spindles, $\frac{1}{20}$ to 2 mm. long, comprise the majority of sponges met on the shore. "Pin-cushions" show also some fine "pinheaded" spicules generally really trefoil—or cross-headed; sponges mostly massive and corky, often bun-shaped. "Claw-sponges" usually show with a good microscope minute C-shaped or G-shaped spicules (often only 3 c. long), the *chelae* or "claws," with commonly a 3-fluked anchor or claw at each end of the C or G; the large spicules being needles, bodkins, or rods (fig. 8) (rarely spindles), and a stout bodkin with prickles on it (*acantho-style*) very characteristic; sponges often hand-shaped, with many fingers or clustered turrets but others form flat crusts. "Fans" are typically shaped like antler-ferns with their branches in one plane (fig. 3) sometimes coalescing into a fan, supported by branching feathery fibres of spicules; needles, with or without spindles, are the commonest spicules, never prickly bodkins or claws, which Dendy considered were possessed ancestrally and lost (1921, "Sealark," p. 111). In "Spindle-sponges" (including fresh-water sponges, "Witches' but-



AFTER SCHULZE IN ZEITSCHRIFT FUR WISSENSCHAFLICHE ZOOLOGIE (ENGELMANN)

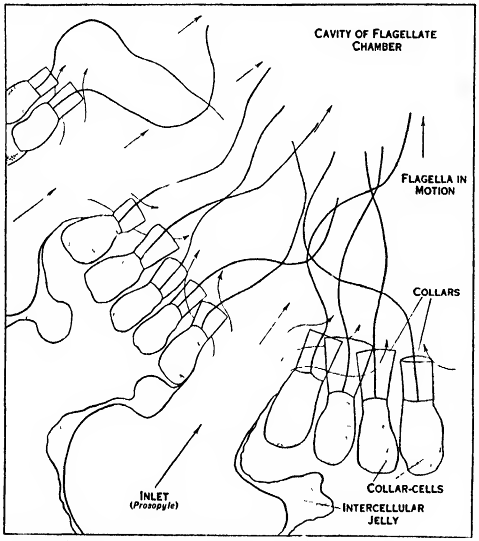
FIG. 5.—TURKEY BATH-SPONGE (EUSPONGIA OFFICINALIS), WITH MAGNIFIED SECTION VERTICAL TO SURFACE

ter" of our ancestors) all the numerous spicules have equal symmetrical ends; ends of neighbouring spindles or rods are generally cemented together by spongin into a network or scaffolding, often rectangular (fig. 11). "Horny Sponges," the marketable kinds, grow in warm seas at 2–20 fathoms depth; in most others the spongin is too hard and brittle to be commercially useful. Inside the fibre of many "Nets" is much sand. The "Chalky Sponges," mostly small, frequent temperate shores; the microscope shows 3-ray and other spicules (fig. 12) soluble in acid. "Banana-chalks" are characterised by tall chimneys, in shape like bananas (Minchin); they are all white to whitish-brown, with many Y-shaped, or more accurately Ꚍ-shaped or T-shaped spicules (fig. 12).

The "Lace-chalks" are coral-red, sulphur-yellow, snow-white and fawn colour, usually making a little crust or cushion of lace-work on the rock with occasional short chimneys (fig. 7); their equiangular spicules have 3 rays about $\frac{1}{10}$ mm. long (fig. 12). "Four-ray Sponges" are characterised by spicules corresponding to the name. They may be symmetrical resembling the calthrops of mediaeval warfare, but usually the ray pointing inwards is of different thickness and length from the other three rays. Of the "Flat Four-rays" *Plakina* has minute, scattered spicules; *Oscarella* has no spicules. The "Grapnel-sponges" show slender spicules with one long arm pointing to the centre of the sponge and three prongs, often curved; they include, however, the "Starry-sponges" (Stellettidae), among which often no four-ray spicule can be found, and which lead us on to the "Gristly-sponges" (*Chondvilla,* Sea-kidney, stars only; *Chondrosia,* Gristle-sponge, no skeleton) and to the "Plane-fruit Sponges,"

[1]Outside marketable Horny Sponges only about half-a-dozen species have popular names, and the groups are known to zoologists by Latin and Greek names, usually of six syllables. For this article the writer has ventured to coin names in English.

which have a crust of stars, with needles and spindles arranged in a radiating skeleton (*Donatia,* fig 2, the Common "Sea Orange," is like a small, yellow, hard golf-ball) The deep sea "Stony Sponges" have shapeless silica laid down on their spicules, mortising them together like the sutures of the skull; their relationships are uncertain, probably they really belong to several groups, some descended from Needle-sponges.



AFTER BIDDER IN QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE

FIG 6—WALL OF FLAGELLATE CHAMBER OF THICK WALLED BANANA-CHALK (LEUCANDRA ASPERA), ARROWS SHOW DIRECTION OF CURRENTS

The neat round holes on the upper surface of a bath-sponge, into which a man's smallest finger will just go, have a very definite size for a good mechanical reason. They are known to zoologists as the "vents" or "oscula," and in healthy life water issues from them continuously so long as they are open The large tube or cavity from which a vent opens (fig 8) is the "cloaca," or main drain The water issues from the cloacae through numerous round holes (fig 8), and water enters to replace it by minute holes all over the surface, in most sponges invisible except with a lens, the name of "pores" is technically confined to them, giving sponges their scientific name of *Porifera.* Except for its million pores, a sponge has no mouth.

From the pores the water enters a system of spaces and tubes branching repeatedly, and from them arise millions of delicate capillaries only some 8μ ($\frac{1}{3000}$ of an inch) in diameter Each of these opens into a tiny cup-shaped chamber (fig 6) known as a "flagellate chamber," because its walls are composed of 100 or 200 of the flagellate collar-cells about 6μ high These wave their flagella, 10μ long, like so many eels fixed with their gills in a net and their tails downstream, and suck the water in through the fine hole or holes in the dome, driving it out into another fine tube, an *efferent* canal, which leads the water away The efferent canals unite together into tubes which unite again into larger tubes, and these into a few main canals which open into the *cloaca,* and so to the *vent* (fig 8). In the cleaned skeleton the canals cannot be traced to their smaller branches, but if a living sponge be killed in strong spirit its whole *canal-system* can be traced out.

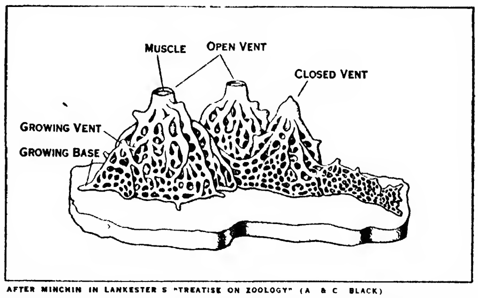
Certainly in the Glass Sponges, and probably in some other sponges, cells in the cavities under the skin and elsewhere also feed, but it has been proved by experiment that the collar-cells feed, and in calcareous sponges only the collar-cells feed There is a good reason for the flagellate chambers being the region in which food is taken in: because from their enormous number the aggregate size of the channel through which the water is passing is largest there, and consequently its motion is slowest, and there is least difficulty in arresting the food Similarly in a sewage-farm the water enters and leaves the field by a quick stream, but moves through the many little ditches so slowly that the land can absorb the manure

Each flagellum with each stroke draws and pushes a little water forward into the chamber, and as the chamber was already full, its walls are stretched and the water inside it is under pressure, which is communicated, with some loss from friction, through the slowly moving water of the efferent canals to that of the cloaca The water inside the sponge is nowhere moving at so high a speed as in the current escaping from the vent, but the flagellate chambers, efferent canals and cloaca form a *pressure-chamber,* from which a jet escapes through the vent The pressure in the sponge's cloaca is kept up by the continuous work of the flagella, the force-pumps of the sponge's hydraulic engine, sucking the water in through the pores and delivering it in a continuous jet from the vent

We know that, when watering a garden with a hose-pipe without any nozzle a wide jet of water will fall to the ground only three feet away, but that diminishing the opening with the finger will result in a ten- or a twenty-foot jet A smaller volume escapes, but therefore the water inside the hose moves more slowly, there is less loss of head by friction inside the hose, and the jet issues at a higher velocity We thus understand why the sponge's vent is so small in comparison with the total width of channel of its many millions of flagellate chambers If the vent were double the size, the current in all the canals and chambers would be speeded up, and the head maintained by the flagella would consequently be lost in friction the jet would be larger but much slower and would not travel so far

It is most important for a sponge in still water that its vent jet should go far The sponge lives by filtering its food from the water, and filters it completely, so that it can get no nourishment by taking in the same water again It lives, also, by taking in oxygen and throwing out carbonic acid and the nitrogenous waste products of its food so that the water which it has used is not only deprived of food, but poor in life-giving oxygen and loaded with deleterious carbonic acid and excreta This valueless and poisonous water must be thrown far away from the entering stream

Sponges are organisms which live on minute particles filtered from the water, and are shaped so as to separate the used water from their new supply. The history of sponges is the history of their adaptation to separate efficiently used outgoing water from the incoming water on which they feed

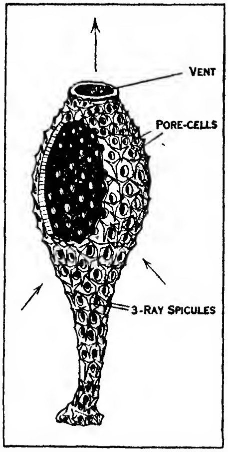


AFTER MINCHIN IN LANKESTER'S "TREATISE ON ZOOLOGY" (A & C BLACK)

FIG 7—LACE-CHALK (CLATHRINA CLATHRUS) SHOWING VENTS CLOSED COMPLETELY BY THE CIRCULAR MUSCLE SEEN INSIDE THE TWO OPEN VENTS Left, the sponge is growing actively, right, the water is too stagnant and the sponge has contracted

Let us examine the arithmetical facts which make it advantageous for unicellular collar-flagellates to unite into a sponge and for elementary thimble-shaped sponges such as the *Olynthus* to unite into a second-grade sponge like *Sycon* (fig 4) in the Chalky Sponges, or like the "Rhagon"; the name given to very

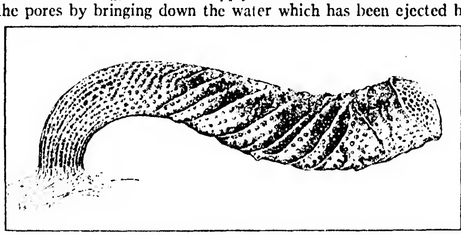
young Four-ray Sponges. Assume that in fig. 8, which illustrates a young Lace-chalk, that the size of the opening of the vent has been drawn exactly equal to the aggregate size of the vents of one hundred thimble-shaped flagellate chambers represented as making up the sponge. There is therefore no advantage from increased speed through a narrow vent, the speed of the water as it leaves the whole sponge being that with which it leaves the component thimbles, but the figure shows the immense advantage which has nevertheless been gained to each component or thimble by combination with its neighbour. Whereas the hundred independent thimbles would have a hundred independent streams, each with its own surface rubbing against the surrounding stationary water and so bringing the jet speedily to a standstill, it will be seen that of the component streams issuing from the common vent only 36 are external, and of these only half the surface is exposed to friction. The jet from the vent has the same velocity as the hundred streams, with their full aggregate weight, but is exposed to less than one-fifth of the total resistance to which the hundred separate streams were exposed. Experimentally the combined jet goes to about ten times the distance to which the individual jet travelled, and for each thimble the water which it sucks in will have, say, $\frac{1}{10}$ the pollution from used water which it would have had if isolated. The principle is akin to the reduction of overhead expenses when small businesses unite.



AFTER HAECKEL'S "DER KALSCHWAMME" (DE GRUYTER & CO.)

FIG. 8.—YOUNG LACE-CHALK (LEUCOSOLENIA PRIMORDALIS) IN "OLYNTHUS" STAGE, MAGNIFIED

Consider the action of the currents around a live bath-sponge at the bottom of a still sea. When the jet from the sponge throws water from the bottom layer of the sea to the layer four feet above it, an equal quantity of water must be pushed out of the four-foot layer to go somewhere; and an equal quantity must come into the bottom layer. If the water be still, these two requirements will be satisfied at once by the formation of a closed eddy like a smoke-ring, which will supply the water which is sucked into the pores by bringing down the water which has been ejected by the vent, so that the work of the flagella will be wasted and will bring to the sponge neither food nor oxygen.



AFTER THOMSON IN THE REPORTS OF THE CHALLENGER EXPEDITION (H.M. STATIONERY OFFICE)

FIG. 9.—VENUS'S FLOWER BASKET (EUPLECTELLA ASPERGILLUM) FROM THE PHILIPPINE ISLANDS, 100 FATHOMS, SHOWING THE LARGE VENT WITH THE CONVEX SIEVE-PLATE PRESUMABLY FACING DOWN STREAM

Water in the sea is rarely absolutely still, even at the bottom on a windless day. Even in the Levant end of the Mediterranean there must be a slight tidal drag for half the day and a shoreward drift when the sun is hot and a seaward drift at night. Such currents, however slow, will bear the outgoing jet to one side: if the jet be only six inches high, the foul water will still come down to pollute three-quarters of the intake; if it be four feet high the whole return will come to the ground free of the sponge, and the purity of the intake will be absolute. *The longer the jet from the vent, the purer will be the water of the intake.* It has been shown for certain sponges by calculation (7) that the diameter of the vent is that which will carry the water to the greatest possible distance for that make of sponge.

Yet in a fine Turkey cup-sponge, however, we find there is no narrow vent at all, but all the efferent cloacae open into a cup-shaped false cloaca, which widens as it goes upwards to a lip several inches across. This is a second method of those arrived at during the 1,400 million years that sponges have existed; by it the angle between the outgoing and incoming streams is increased from the right angle of the bath-sponge, and becomes exceedingly wide; so that, however slow the outgoing stream, the diameter of the circular eddy is so large that the slightest drift of the surrounding water must take the polluted effluent away from the intake. In the fan sponge (fig. 3), where the vents and pores are on opposite sides of an upright plate, the angle between intake and effluent is 180°, so that the used water *never* returns. This, however, is only advantageous where the drift of the sea is unchanging in direction. Such a condition exists at the bottom of the great oceans, where there is a slow current from pole to equator, and in some of the deeps around Scotland; but in a tidal run the sponge for a third of its life would have the tide pressing the water into the vents and out of the pores. In the tidal English Channel the peculiar Cannon-sponge accomplishes the advantageous result in a wholly different manner. It points its wide vent horizontally, looking like an 18th century cannon; but its round base is carried on a thin stalk like a pig's tail, so that as the tide sweeps round it, swivels with it, and always points down stream. A deep-sea Claw-sponge, known as the Umbrella-sponge has also a flexible stalk so that the convex side of the umbrella must be down stream.

Appreciating the advantages of completely separating outflow from intake, it is possible to conceive how sponges arose, and such very similar forms have been evolved along so many different lines of descent. Glass Sponges appear as the offspring of branching colonies of unicellular collar-flagellates which learned to secrete a substance crystallising into rectangular scaffoldings, on which they can set themselves like a salmon-net across the slow currents of the deep ocean and so obtain an endless supply of the suspended organic particles. They have existed since the earliest fossiliferous rocks, and probably twice as long; but with no hydraulic system to form a forcible jet from the vent, they have been unable to live except in oceanic currents. The True Sponges are the offspring of multicellular gelatinous colonies of collar-flagellates (such as *Proterospongia*); they have learned to shape their gelatinous aggregate so as to unite the currents made by individual collar-cells, and on various plans to direct the streams of used water away from the approaching drift of purer water; thus they can support existence in still caves and tide-pools.

AFTER SOLLAS

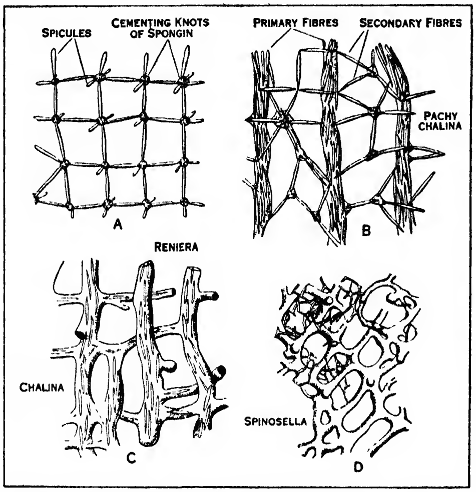
FIG. 10.—"CHONE" WHICH REGULATES THE AFFERENT STREAM IN CYDONIUM EOSASTER, A GRAPNEL-SPONGE

(A) Dermal pores; (B) Solid-stars; (C) Contractile cells; (D) Grapnel spirule; (E) Flagellate chambers; (F) Efferent canals; (G) Afferent canal

G. H. Parker found that the pressure in the chambers of *Stylotella* (a Claw-sponge) supports a column of water $3\frac{1}{2}$ to 4 mm. above the surrounding surface (6). The velocity of the jet from the vent in *Leucandra aspera* is about 8 cm. a second, throwing 5 gallons a day to a distance of nine inches. The velocity at the same moment past the collar-cells (fig. 6) was 2 to 4 cm. an hour (7) taking 1 or 2 seconds to pass the cell 12μ high.

Spongin.—Chalky Sponges have no spongin, though the red and yellow pigments may be of an allied substance; Four-ray Sponges have little or none. Needle-sponges have commonly a basal spongin-plate, and their spicules are cemented by more or less spongin into bundles and networks, the claw-sponges showing so

much spongin that some (as *Ectyon* and *Ophlitospongia*) may easily be mistaken for Horny Sponges; among the Chalinine Spindle-sponges, the spicules are sometimes reduced to a few spindles or rods inside horny fibres In Horny Sponges the spongin of the fibres is secreted by flask-shaped cells which are known as spongoblasts. An examination of the unmarketable sponge called *Ircinia,* shows that similar cells are forming the horny cuticle of



AFTER MINCHIN AND DANDY IN LANKESTER'S TREATISE ON ZOOLOGY (A & C BLACK)

FIG 11 —SKELETONS OF SPINDLE-SPONGES

The knots of spongin uniting single spicules in A are found in the secondary network of B, where the primary fibre has several rows of spicules wholly embedded in spongin. In C the single spicules of secondary fibre are also embedded, while in D, much spongin fibre is apparently free from spicules

the outer surface, and that the horny fibre is secreted by a tube of spongoblasts, pouched in from the sticky surface and carrying with it the adherent sand (Projection of the fibre is not the condition in healthy life, but is due to the shrinkage as water drains from the sponge) Similarly shaped cells secrete the spongin cementing together the spicule-bundle in claw-sponges.

Spicules.—Sponge-spicules are formed by cells In the calcite three-ray spicules the Chalky Sponges (*Calcarea*) each ray is formed by two cells, the first rudiment being apparently non-crystalline, with the three rays separate (Minchin, 1898), then the rays become crystalline and unite, the three-ray spicule being optically one crystal (Sollas, 1885) The optic axis of the crystal is perpendicular to the plane of the rays in the symmetrical spicules of the Lace-chalks, and inclined to it in the upsilon-shaped "alate" spicules (fig 12) of the Banana-chalks. The spindles and club spicules of Banana-chalks are each formed by two cells (Bidder, 1898, Woodland, 1905, Minchin, 1908). In Grapnel-sponges Dendy (Quart, *Micr Soc.* 1926) found a slender non-siliceous rudiment, the "proto-rhabd," either laid down by cells of unusual appearance called "formative cells," or, as he afterwards supposed, reproduced like a bacterium from a parent proto-rhabd, several sponge-cells (silico-blasts) gather round this rudiment and pour opal over it and the formative nuclei In Glass Sponges Ijimi describes a large number of cells as taking part in the formation of each spicule: the massed cells so engaged are the only cells of Hexactinellids, except the gemmule-cells, which show a gelatinous agglomeration such as is common in the True sponges

Collar-cells.—The "collar" is not homogeneous, but a tubular tassel of sticky parallel rods—in *Grantia* 20–30, in *Clathrina* or *Halichondria* fewer The rods can contract, thickening as they do so (Julian Huxley, 1911); they are not proved prehensile The cell contains food-reserve granules, transparent after starvation, and (Gatenby—*see* "Cytology") a Golgi body. In Chimney-chalks the nucleus is near the top of the cell and connected with the flagellum (8, p. 21; Bidder 1898), in Lace-chalks it is connected in young cells (Robertson & Minchin, 1910), but separates and passes to the base.

Movement.—In many sponges especial fusiform cells form muscular bands and sphincters (fig 10) whose contraction either closes a channel for water or alters its width No sponge has any nervous mechanism. The flagellate cells wave their flagella without correlation, in different periods and at different phases The contractile cells contract to direct stimulus, or are restrained from contraction by direct stimulus (b) There are no sensory cells and no nerve fibres

Within the jelly of the sponge-body, ova and other cells wander about with amoeboid movements, sucking from the bases of the collar-cells their food-resources and eating any intrusive foreign particle or organism encountered in the jelly In the fresh-water *Spongilla* (9) the collar-cells are described as throwing carmine into the jelly and the amoeboid cells as devouring it, the green unicellular alga which colours *Spongilla* grows uninjured while *Spongilla* is well fed, but forms a reserve, being eaten by the amoeboid cells when other supplies fail

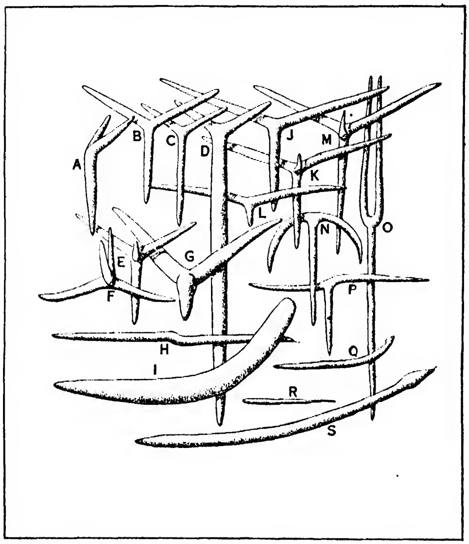
In the young fixed larva the cells next the rock necessarily move over it to form a good disc of adhesion Such movements may result in the whole young sponge changing its place, a gemmule of *Spongilla* allowed to fix at the bottom of the glass side of the aquarium will crawl some little way up the side, until light and other reactions are less different on the upper and lower sides of its base

The most remarkable change of form and position in cells is that which gives rise to the pores in Lace-chalks The small afferent holes through which water enters the flagellate chambers consist in Calcareous sponges each of a single perforate cell (Bidder, 1891) In the Lace-chalks any one of the external cells can stretch down through the sponge-wall to the flagellate surface, push in between the collar-cells and perforate itself to make a pore (Minchin, 1892) These "porocytes" in unhealthy conditions crawl over and completely cover the collar-cells The occasional vertical ray, which in certain species of Lace-chalks converts some of the three-rayed spicules into four-rayed spicules, is always added by a porocyte (Minchin)

Nutrition.—In Banana-chalk (*Leucandra aspera*, fig 6) 20 minutes after feeding with carmine the interstitial jelly between the collar-cells (fig 5) is loaded with carmine particles and every collar-cell has several adhering to it or in vacuoles, generally near its base After 4 hours the collar-cells are crowded with carmine, after 18 hours there are a few fine particles, but after a few hours more it has all disappeared Food seems to be taken in at the sides of the collar-cell (9) (as in collar flagellates), but probably also inside the collar, and passes into vacuoles with an acid reaction After about 6 hours the vacuole has become a faecal bolus of transparent mucilaginous substance (Cotte [1903, p 459] observed the reaction to be alkaline) containing refringent granules, probably calcareous This moves about in the upper part of the living collar-cell, from which it is presently cast out inside the collar and so into the efferent current If a sponge, gathered from exposed rock at low-tide, be placed in fresh sea-water, the stream from the vent, so soon as the current resumes, is seen to bear a number of white specks and clots, heavier than water, which are the aggregated faeces that have accumulated during the period of quiescence

Reproduction and Growth.—Increase of sponges is mainly by vegetative growth *Leucosolenia variabilis* (fig 4) sends out stolons along the rock from which tubular chimneys grow up in apparently endless succession *Clathrina coriacea* (fig 4), though complete in all its parts as a cushion a quarter-of-an-inch wide, will weave its lace over the rock till it covers many inches; the crusting Needle-sponges such as *Halichondria* (fig 4) or the fresh-water *Ephydatia* can extend their crusts indefinitely Rate of growth varies enormously with conditions a calcareous sponge hanging from a boat in harbour may add 40% a day to its weight (7, p. 315), while the same species on a tidal rock may only in-

crease 2% a day. The tidal sponges shown in fig. 4 are all annual, and in the most favourable situation *Sycon* or *Grantia* may grow to 10 inches instead of 2 inches long. Vosmaer's observation on the gemmule of the "Sea-orange" (13, p. 440) gives an increase of about 17% a day, but Rathbun's artificial sponge-cuttings of Horny sponges in Florida from $2\frac{1}{2}$ cubic inches grew to $12\frac{1}{2}$ cubic inches in two months (*see* Bidder, 1896, p. 201), which is only



AFTER MINCHIN IN LANKESTER'S "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 12.—CALCITE SPICULES OF CHALKY SPONGES

(A. B. E. F. G.) *Ascaltis cerbrum lacunosa;* (C) *Clathrina blanca;* (D. H.) *Clathrina lacunosa;* (I) Lace-chalks: *Ascandra falcata;* (J. K.) Y-shaped (alate) spicules of *Leucosolenia variabilis;* (L) alate and (O) tuning-fork spicule of *Lelapia australis;* (P) T-spicule and (Q) lance-spicule of *Leucosolenia variabilis;* (R) needle and (S) lance-spicule from *Leucosolenia complicata*

3% a day. Mr. L. R. Crawshay has told the writer that his sponge-cuttings in the Bahamas increase more slowly than this, growing in a year to 2 or $2\frac{1}{2}$ times their volume, and that the large Wool sponges increase in volume annually from 0% to 80% (say, 50% a year); he considers the largest ($2\frac{1}{2}$ feet across) to attain an age of at least 25 years. The Wool sponges, Velvet sponges and Mediterranean Honeycomb sponges are probably the largest of all sponges. Cresswell (15) describes a circular specimen of the last species 36 inches across and 12 inches high. The Needle-sponge "Neptune's Cup" (*Cliona*) forms in the East Indies a rigid stalked goblet a yard high and more than a foot across the rim; it is one of the Pin-cushion sponges, and when young bores in soft limestone or sea shells, producing the worm-eaten appearance often seen in oyster-shells; in temperate seas its adult form is a yellowish corky sponge several inches in diameter, formerly known as *Raphyrus.*

Depleted fisheries can be restored by fixing to tiles cut pieces of sponge, each of which grows into a new sponge. Some sponges detach portions of themselves as *buds. Leucosolenia* (Vasseur, 1880) breaks off the end of a branch, which falls blind-end down and grows into a complete sponge. In *Oscarella lobularis* the tip of a lobe will become thin-walled and then be nipped off; having no skeleton it does not sink, but may exist for a fortnight as a free-swimming sponge before it fixes on the bottom and grows into a flat lobed sponge like its parent (F. E. Schulze, 1879 [β]).

The form of reproduction especially characteristic of sponges is *gemmulation,* found in Glass Sponges, Four-rays, Needle-sponges, Horny Sponges and Lace-chalks, but never recorded in Banana-chalks, among which sex is highly developed. A sponge-gemmule arises by a number of undifferentiated cells coming together and enveloping themselves in some sort of membrane or epithelium. In the Sea-orange the growth of a radial bundle of spicules in the parent forces the gemmule to the exterior, where it drops off; in Grapnel-sponges the gemmules appear to be thrown out in the cloacal current; in Glass Sponges and in Claw-sponges the exterior cells of the gemmule become flagellate and it swims away like a "planula" larva; in the Sea fig (fig. 2) the gemmules remain during healthy life sealed in envelopes of spongin just above the sponginous base of attachment, ready to reproduce the sponge if it be destroyed. Gemmules of Fresh-water Sponges are similarly protected by chitinous shells, reinforced by various rods or spindles (*Spongilla*) or amphidiscs (*Ephydatia*). After years of desiccation they grow new *Spongilla* when water returns. Fresh-water Sponges of temperate climate die in winter, and the gemmules show like seed-pearls among the remnants of the skeletons, which they reclothe in spring. Young sponges of the same species, growing near each other, generally fuse together if their growth brings them into contact (not in the case of bath sponges); when this happens to two grown from gemmules of different parents, the resulting sponge will contain cells of two heredities and in its gemmule both strains may be present.

There is also, at least in some groups of sponges, true sexual reproduction. The development of ova into larvae may be observed readily in Chalky or Horny Sponges, in *Halisarca* (a slime-covered purple crust, without skeleton, probably closely allied to Bush Horny Sponges) in *Oscarella,* Spindle-sponges and Claw Sponges. It has only recently (Burton, 1928) been recorded in a Sea-orange, though this species has been observed constantly for 150 years. It has never been recorded in Grapnel-sponges or Fan-sponges, it is rare among Pin-cushions and Ijima was unable to find it among Glass Sponges.

Many descriptions of spermatogenesis in sponges appear to the descriptions of parasitic flagellates (*Syncrypta spongiarum,* see *Linnean Soc. Journ.* Z. xxxiv.) and when spermatozoa are figured there is rarely evidence that they are not alien. In *Grantia compressa* Gatenby (1920, ibid.) has shown both the spermatogenesis and the fertilisation of the ovum by the spermatozoon through the intermediary of a collar-cell, in *Sycon raphanus;* Bidder (ibid.) has shown the direct fertilisation of the ovum under the cloacal surface by the spermatozoon. The spermatozoon was stiff-tailed when seen alive; it is possible that the tail only comes into play when the ovum is near.

Segmentation of the ovum in the Calcaronea produces a ring of eight similar cells (recalling the colonial Flagellates *Stephanosphaera* and *Cyclonexis*), each of which then divides horizontally into a smaller and a larger cell; from the eight smaller cells is produced a hemisphere of flagellate cells and from the eight larger a hemisphere of rounded cells. This "amphiblastula" larva swims for a day or two, then the flagellate hemisphere is sucked inside the other and becomes concave, the two-layered cup so formed fixing by its lip to a rock. The rounded cells secrete the spicules and form the dermal layer, a vent bursts through both layers, pores are formed, and the young sponge is a two layered cylinder whose lower end is closed by the rock, the perforate walls and flagellate lining giving a resemblance to the *Olynthus* stage of *Clathrina* (fig. 8). Spicules sometimes appear while the larva is still free-swimming, and (Bidder, *Brit. Assoc.,* 1928) the early division into two classes of cells occurs from the necessity of separating the spicule-forming cells from the locomotor cells, so that the activity of the flagellate cells shall not be hindered by the deposit of calcite or opal in their substance. There is no such division in *Oscarella,* which has no skeleton, but in most sponges the larva is egg-shaped with a surface of flagellate cells covering a solid interior of spicule-forming cells.

The fixed "Olynthus" larva of *Sycon* is subsequently metamorphosed into a Sycon by the flagellate cells retreating into radial tubes; this may be considered to repeat a change which took place in racial history.

SPONSOR, one who stands surety for another (from Lat. *spondere*, to promise), especially in the rite of Christian baptism, a godfather or godmother. The practice originated not in infant baptism, but in the custom of requiring an adult pagan who offered himself for the rite to be accompanied by a Christian known to the bishop, who could vouch for the applicant and undertake his supervision, thus fulfilling the function performed in the Eleusinian mysteries by the *mystagogus* The Greek word for the person undertaking this function is ἀνάδοχος, to which the Latin *susceptor* is equivalent. The word "sponsor" in this ecclesiastical sense occurs for the first time, but incidentally only, and as if it were already long familiar, in Tertullian's treatise *De baptismo* (ch 18), where, arguing that in certain circumstances baptism may conveniently be postponed, especially in the case of little children, he asks, "For why is it necessary that the sponsors likewise should be thrust into danger, who both themselves by reason of mortality may fail to fulfil their promises, and may also be disappointed by the development of an evil disposition [in those for whom they become sponsors]?"

The sponsors here alluded to may have been in many cases the actual parents, and even in the 5th century it was not felt to be inappropriate that they should be so; Augustine, indeed, in one passage appears to speak of it as a matter of course that parents should bring their children and answer for them "tanquam fidejussores" (*Epist . . . ad Bonif.* 98), and the oldest Egyptian ritual bears similar testimony Elsewhere Augustine contemplates the bringing of the children of slaves by their masters, and of course orphans and foundlings were brought by other benevolent persons.

The comparatively early appearance, however, of such names as *compatres, commatres, propatres, promatres, patrini, matrinae,* is of itself sufficient evidence, not only that the sponsorial relationship had come to be regarded as a very close one, but also that it was not usually assumed by the natural parents. How very close it was held to be is shown by the Justinian prohibition of marriage between godparents and godchildren. On the other hand, the anciently allowable practice of parents becoming sponsors for their own children, though gradually becoming obsolete, seems to have lingered until the 9th century, when it was at last formally prohibited by the council of Mainz (813). For a long time there was no fixed rule as to the necessary or allowable number of sponsors and sometimes the number actually assumed was large. By the council of Trent, however, it was decided that one only, or at most two, these not being of the same sex, should be permitted.

The rubric of the Church of England, that "there shall be for every male child to be baptized two godfathers and one godmother, and for every female one godfather and two godmothers," is not older than 1661; the sponsors are charged with the duty of instructing the child, and in due time presenting it for confirmation. In the Roman Catholic Church the spiritual relationship established between the sponsor and the baptized, and the sponsors and the parents of the baptized, constitutes an impediment to marriage. (*See* MARRIAGE; CANON LAW.)

SPONTINI, GASPARO LUIGI PACIFICO (1774–1851), Italian composer, was born on Nov. 14, 1774, at Majolati (Ancona) in Italy. He was the son of a poor cobbler and was intended for the priesthood. But he obtained lessons from Kapellmeister Quintiliani, and in 1791 went to the Conservatorio de' Turchini at Naples, where he studied under Paisiello, Cimarosa and Fiorivanti By 1799 he had already written and produced eight operas. After becoming court composer to King Ferdinand of Naples in this year an intrigue with a princess of the court compelled Spontini to leave Naples in 1800 In 1803 he settled in Paris, where he had no success until the production of *Milton*, a one-act opera, in 1804. Thereafter his powers and ambitions steadily developed, being manifested to the full for the first time in *La Vestale*, produced on Dec 15, 1807. *Ferdinand Cortez* was received with equal enthusiasm in 1809; but *Olympia* (1819) had less success

Spontini had been appointed director of the Italian opera in 1810; but his quarrelsome and grasping disposition led to his summary dismissal two years later, and, though reinstated in 1814, he voluntarily resigned his post soon afterwards In 1820 he settled in Berlin by invitation of Frederick William III, commissioned to superintend all music performed at the Prussian court and compose two new grand operas, or three smaller ones, every three years But he began by at once embroiling himself with the intendant, Count Bruhl *La Vestale*, *Ferdinand Cortez* and *Olympia*—the last two entirely remodelled—were produced with great success in 1821 But Spontini's fame was entirely eclipsed by the appearance of Weber's *Der Freischutz* A new opera, *Nourmahal*, founded on Moore's *Lalla Rookh*, was performed in 1822, and another, entitled *Alcidor*, in 1825, and in 1826 Spontini began the composition of *Agnes von Hohenstaufen*, (produced in 1829), which undoubtedly will rank permanently as his greatest work.

Dismissed from his court position in 1841, he settled in Paris In 1850 he retired to his birthplace, Majolati, and died there on Jan. 14, 1851.

SPOON, a table implement, bowl-shaped at the end, with a handle varying in length and size. From the derivation of the word the earliest northern European spoon would seem to have been a chip or splinter of wood, the Greek κοχλιάριον (Lat *cochleare*) points to the early and natural use of shells, such as are still used by primitive peoples Examples are preserved of the various forms of spoons of ivory, flint, slate and wood, many of them carved with the symbols of their religion, used by the ancient Egyptians The spoons of the Greeks and Romans were chiefly made of bronze and silver, and the handle usually takes the form of a spike or pointed stem Mediaeval spoons for domestic use were commonly made of horn or wood, but brass, pewter and "latten" spoons appear to have been common about the 15th century. The full descriptions and entries relating to silver spoons in the inventories of the royal and other households point to their special value and rarity. The earliest English reference appears to be in a will of 1259 In the wardrobe accounts of Edward I for the year 1300 some gold and silver spoons marked with the fleur-de-lis, the Paris mark, are mentioned. One of the most interesting mediaeval spoons is the coronation spoon used in the anointing of the sovereign. The sets of spoons popular as christening presents in Tudor times, the handles of which terminate in heads or busts of the apostles, are a special form to which antiquarian interest attaches. (*See* APOSTLE SPOONS.) The earlier English spoon-handles terminate in an acorn, plain knob or a dia-

CHINESE BRONZE SPOONS OF THE CHOU DYNASTY

mond; at the end of the 16th century the baluster and seal ending becomes common, the bowl being "fig-shaped." At the Restoration the handle becomes broad and flat, the bowl is broad and oval and the termination is cut into the shape known as the *pied de biche,* or hind's foot. In the first quarter of the 18th century the bowl becomes narrow and elliptical, with a tongue or "rat's tail" down the back, and the handle is turned up at the end. The modern form, with the tip of the bowl narrower than the base and the rounded end of the handle turned down, appeared about 1760.

See C. J. Jackson, "The Spoon and its History," in *Archaeologia* (1892), vol. liii.; also Cripps, *Old English Plate.*

SPOONBILL, a bird, once called shoveller (*q.v.*), *Platalea leucorodia*, related to the stork. The spoonbill became extinct as a British breeding bird about 1660, though there is reason to hope it may again nest in Norfolk in the near future. It breeds in Holland, Spain, the Danube basin, and thence across Asia to India, as well as in North Africa. The plumage is white in both sexes, with a broad flat bill with which it sifts small animals from the mud of ponds, etc. Allied species replace it in South Africa and Australia. The pretty roseate spoonbill (*Ajaja ajaja*) of America is tropical and sub-tropical, and is found as far north as the Gulf States, where, however, it has been nearly exterminated. It has a deep pink plumage, deepening in places to crimson.

BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

THE ROSEATE SPOONBILL (AJAJA AJAJA), THE ONLY VARIETY FOUND IN AMERICA

Spoonbills breed in companies, often with herons, in trees or reed-beds, laying four white eggs, sparingly blotched with light red.

SPORADES, the scattered islands of the Greek Archipelago, distinguished from the Cyclades, which are grouped round Delos, and from the coastal islands of Europe and Asia. Ancient and modern writers differ as to the list. The Doric Sporades—Melos, Pholegandros, Sikinos, Thera, Anaphe, Astypalaea and Cos—were by some considered a southern cluster of the Cyclades. In modern times the name Sporades is applied to two groups: *The northern Sporades* lie north-east of Negropont (Euboea), Skiathos, Skopelos and Ikos being included in the department of Magnesia, and Scyros (*q.v.*) in that of Euboea. Scyros has a fine harbour. Skiathos is beautifully wooded; the town overlooks an excellent harbour. Skopelos is also well wooded. Almost every householder in both islands is the owner, joint owner or skipper of a sailing ship. *The southern Sporades,* lying off the south-west of Asia Minor, formerly included in the Turkish vilayet of the "Islands of the White Sea," are as follows: Icaria, Patmos (*q.v.*), Leros, Calymnos, Astypalaea (Astropalia or Stampalia), Cos (Turk. *Stanko, q.v.*), Nisyros, Tilos or Episcopi, Syme, Khalki, Rhodes (*q.v.*) and many smaller isles.

See C. Bursian, *Geographie von Griechenland* (Leipzig, 1862–71), ii. 348 ff.; L. Ross, *Reisen auf den Griechischen Inseln* (1840–45).

SPOROZOA, a group of parasitic Protozoa which produce unicellular spores within a tough envelope or cyst. Since formerly various Protozoa, which had only this character in common and were not truly related to one another, were classed with the Sporozoa, some protozoologists have split up the class Sporozoa into two classes, Amoebosporidia and the true Sporozoa. For further particulars *see* PROTOZOA.

SPORTS, ARTICLES ON. Almost all varieties of indoor and outdoor sport have separate articles in this *Encyclopædia.*

Among the chief are: ATHLETIC SPORTS; ANGLING; BASEBALL; BILLIARDS; BOWLS; BOXING; BRIDGE; BULL-FIGHTING; CAMPING OUT; CHARADE; CHESS; CONJURING; COURSING; CRICKET; CYCLING; DRIVING; FALCONRY; FOOTBALL; GAME; GAMES, CLASSICAL; GOLF; GYMKHANA; GYMNASTICS AND GYMNASIUM; HOCKEY; HORSE RACING; HUNTING; HURDLE RACING; JUMPING; LACROSSE; LAWN TENNIS; MODEL YACHTING; MOUNTAINEERING; PATIENCE; PIGEON-FLYING; PIG-STICKING; PINOCHLE; POKER; POLO; PUGILISM; RACQUETS; RIDING; ROLLER-SKATING; ROWING; RUNNING; SHOOTING; SKATING; SKI; SPORT; STEEPLECHASE; SWIMMING; TENNIS; TOBOGGANING; TOREADOR; TOURNAMENT; TUG-OF-WAR; VENTRILOQUISM; WALKING RACES; WATER-POLO; WEIGHT-THROWING; WHIST; WRESTLING and YACHTING.

SPORTS, THE BOOK OF, or more properly the DECLARATION OF SPORTS, an order issued by James I. in 1617 on the recommendation of Thomas Morton, bishop of Chester, for use in Lancashire, where the king on his return from Scotland found a conflict on the subject of Sunday amusements between the Puritans and the gentry, many of whom were Roman Catholics. Permission was given for dancing, archery, leaping, vaulting and other harmless recreations, and of "having of May games, Whitsun ales and morris dances, and the setting up of May-poles and other sports, therewith used, so as the same may be had in due and convenient time without impediment or neglect of divine service, and that women shall have leave to carry rushes to church for the decorating of it." On the other hand, "bear and bull-baiting, interludes, and (at all times in the meane sort of people by law prohibited) bowling" were not to be permitted on Sunday (Wilkins, *Concilia*, iv. 483).

In 1618 James transmitted orders to the clergy of the whole of England to read the declaration from the pulpit; but so strong was the opposition that he prudently withdrew his command (Wilson, in Kennet, ii. 709; Fuller, *Church History,* v. 452). In 1633 Charles I. not only directed the republication of his father's declaration (Rushworth, ii. 193), but insisted upon the reading of it by the clergy. Many of the clergy were punished for refusing to obey the injunction. With the fall of Laud all attempts to enforce it necessarily came to an end.

SPOTSWOOD, ALEXANDER (1676–1740), American colonial governor, was born, of an old Scots family, in Tangier, Africa, in 1676. He served as aide to Marlborough in the War of the Spanish Succession, and was wounded at Blenheim. He was appointed lieutenant-governor of Virginia in 1710, and was received with enthusiasm, because he brought to the colony the privilege of *habeas corpus;* his term as governor closed in September 1722, but he remained in Virginia, living near his iron-works in Germanna, a settlement of Germans, on the Rapidan in Spottsylvania county (named in his honour); and he was deputy postmaster-general of the colonies from 1730 to 1739. He was the first representative of the British government in America who fully appreciated the value of the western territory. As governor he recommended the establishment of a Virginia company to carry on trade with the Indians, he urged upon the provincial government and also upon the British authorities the wisdom of constructing forts along the frontier, and he personally organized and conducted in 1716 an exploring expedition into the Shenandoah Valley. He developed the iron industry of Virginia, promoted the religious education of the Indians, and tried to advance the interests of education, especially the College of William and Mary. He died at Annapolis, Md., June 7, 1740.

See R. A. Brock (ed.), "The Official Letters of Alexander Spotswood" (with a memoir), in *The Collections of the Virginia Historical Society* (1882–85).

SPOTTED JEW-FISH (*Promicrops gitaiara*), an immense marine bass (fam. *Serranidae*) found on the coasts of tropical America, which sometimes attains a length of 8 ft. and a weight of about 700 pounds. The adult is dull olive-brown in colour, with faint spots and bands; the young are yellowish-green, with dark cross-bars and spots about the head. The South Pacific jew-fish reaches 12 ft.

THE SPOTTED JEW-FISH (PROMICROPS GITAIARA)

SPOTTISWOODE (SPOTTISWOOD, SPOTISWOOD or SPOTSWOOD), **JOHN** (1565–1639), archbishop of St. Andrews and his-

torian of Scotland, eldest son of John Spottiswood, minister of Calder and "superintendent" of Lothian, was born in 1565. He was educated at Glasgow University (M.A. 1581), and succeeded his father in the parish of Calder in 1583. In 1601 he attended Ludowick, duke of Lennox, as his chaplain, in an embassy to the court of France, returning in 1603. He followed James to England on his accession, but was the same year nominated to the see of Glasgow, his consecration in London, however, not taking place until October 1610 On May 30, 1605 he became a member of the Scottish privy council In 1610 he presided as moderator over the assembly in which presbytery was abolished, in 1615 he was made archbishop of St. Andrews and primate of Scotland, and in 1618 procured the sanction of the privy council to the Five Articles of Perth with their ratification by parliament in 1621. In 1633 he crowned Charles I at Holyrood In 1635 he was appointed lord chancellor of Scotland, an office which he retained till 1638. He was a spectator at the riot of St. Giles's, Edinburgh, on July 23, 1637, endeavoured in vain to avoid disaster by concessions, and on the taking of the Covenant perceived that "now all that we have been doing these thirty years past is thrown down at once" He escaped to Newcastle, was deposed by the assembly on December 4, on trivial charges, and died in London on November 26, 1639, receiving burial in Westminster Abbey His most considerable work was *The History of the Church and State of Scotland* (London, 1655, *seq.*).

See the accounts prefixed to the first edition of Spottiswoode's *History of Scotland* and to that published by the Spottiswoode Society in 1851, also David Calderwood's *Hist of the Kirk of Scotland* (1842–1849)

SPOTTISWOODE, WILLIAM (1825–1883), English mathematician and physicist, was born in London on Jan 11, 1825 He was educated at Laleham, Eton, Harrow, and Balliol college, Oxford, where he obtained a first-class in mathematics in 1845, and then took his father's place as partner in the firm of Eyre and Spottiswoode, printers, in which business he was engaged until his death on June 27, 1883 His first mathematical publication was *Meditationes Analyticae* in 1847 He was chiefly interested in determinants His elementary treatise on this subject (1851) was the first published work on determinants His researches are also concerned with the contact of curves and surfaces, the polarization of light, and electrical discharge in gases.

A list of his papers is given in *Nature*, vol xxvii

SPOTTSYLVANIA, a county of Virginia, U S A, so called after Alexander Spotswood (*q v.*), lieutenant governor of Virginia in 1710–22, who owned extensive estates and mines therein It is bounded on the north by the Rapidan and Rappahannock rivers and on the south by the North Anna It is celebrated as containing several of the most famous battle-fields of the Civil War—Fredericksburg, Chancellorsville, the Wilderness and particularly that of Spottsylvania Court House, where the armies of Grant and Lee contended for nearly two weeks (May 8–21, 1864)

SPRAT, THOMAS (1635–1713), English divine, was born at Beaminster, Dorsetshire, and was educated at Wadham College, Oxford (1657–70). He became a prebendary of Lincoln in 1660. He wrote a poem *To the Happie Memory of the most Renowned Prince Oliver, Lord Protector* (1659); *Observations upon Monsieur de Sorbier's Voyage into England* (London, 1665), and a *History* of the Royal Society of London (London, 1667), which Sprat had helped to found. In 1684 he became bishop of Rochester As dean of Westminster he directed Wren's restoration of the abbey. He died on May 20, 1713

SPRAT, a marine fish (*Clupea sprattus*), one of the smallest species of the genus *Clupea* or herrings, rarely exceeds 5in in length, and occurs in large shoals on the Atlantic coasts of Europe The sprat spawns in the open sea from February to May. Its eggs are buoyant and pelagic and easily recognized. The sprat is one of the more important food-fishes on account of the immense numbers in its shoals. In Norway large quantities are tinned in oil, or are eaten fresh, pickled, smoked or prepared as anchovies

SPRAYING MACHINERY. The discovery that certain substances in weak solutions or emulsions or in the form of powder could be used to combat many insect and fungus pests of farm, garden and orchard crops and also some weeds led to the development of mechanical devices for spraying the liquids or dusting the powders over the stems and foliage of plants and trees. The name sprayer is usually applied to the machines which distribute liquids and that of duster to those used for distributing powders, though the two types are also referred to as wet and dry sprayers respectively

Sprayers utilize pressure to force the liquid through a specially constructed nozzle which splits it up into very fine particles or spray These machines differ according to (*a*) the complexity of the mechanism; (*b*) the kind of power by which they are operated, (*c*) the method of transport adopted, and (*d*) the diversity of their accessories Before dealing with the main types of sprayers it may be as well to describe the various accessories Nozzles are of two principal types one produces a jet in the form of a hollow cone and the other a fan-shaped jet—the latter is becoming obsolete There are, however, many variations and each manufacturer has practically developed a distinct nozzle The cone-shaped jet is produced by forcing the liquid into a small chamber at a tangent and then through a small hole If the hole is very small a spring-loaded pin is provided for cleaning the outlet, should it become choked In some sprayers apertures of different sizes may be fitted so that sprays of varying degrees of fineness may be used The fan-shaped jet is produced by forcing the liquid against a lip, the fineness of the spray depending on the width of the exit aperture Lances are hollow tubes or rods, to which the nozzles are attached and are used to bring the spray close to the plant or tree and usually have rubber connections so that they can be operated in any direction Spray guns are used in place of lances on powerful machines They enable the spray to be adjusted by turning a handle which alters the pressure. By using these devices it is possible to spray foliage on the ground and then by increasing the pressure to spray the tops of trees Spray booms which consist of pipes carrying nozzles at intervals are attached to the machine (which is carried on wheels or a cart) and are used for spraying such field crops as potatoes, and such weeds as charlock. For hops the spray booms are arranged more or less vertically, and the machine is drawn between the rows Mixers, stirrers or agitators are often fitted to sprayers in order to ensure the liquid being as uniform as possible, these devices usually operate automatically when the machine is in use. Stop-cocks or cut-offs are used for stopping the flow of liquid at the discretion of the operator.

Manual Sprayers.—The simplest form of sprayer consists of a hand pump with a suitable nozzle, attached to or used in conjunction with an ordinary bucket Another simple type is the knapsack sprayer which, as its name implies, is carried on the back of the operator This type may make use either of a direct pump or of an air-pump and compressed air chamber for the purpose of projecting the liquid If the latter device is employed a number of preliminary strokes of the air-pump are required before spraying in order to produce the necessary pressure In either case the machine embodies a container for the liquid (usually 2 or 3 gallons) a lance and nozzle Larger machines are carried on a wheeled framework or in a cart.

Power Sprayers.—There are two kinds of sprayers operated by power, namely, those which are driven from the transport wheels and those driven by engines mounted on the same framework The first type are used mainly for agricultural crops for which they are very suitable, whilst the latter type are more suitable for spraying large orchards. In both cases it is usual to employ horses for hauling the machines, though sprayers which are both propelled and operated by internal combustion engines are being used in America, where large orchards or plantations have to be treated. The essential components of these machines do not differ in principle from those described above For spraying tall trees a special type of nozzle is sometimes employed, which is so constructed that the liquid is carried in an unbroken stream to the requisite height before it dissolves into spray high pressure and considerable power are required to operate machines when using these nozzles, the largest engines developing 60 h p

Stationary spray plants are used to some extent in the United

States, especially in the apple regions of the State of Washington. Such a plant consists of a spray tank, a pump, a gas engine or electric motor, and a pipe line equipped with faucets.

Dusting Machines.—These machines may be classified in a similar way to sprayers but very few accessories are necessary and generally speaking the machines are of simpler construction: an air blast, produced by means of a fan or bellows, is used to blow the dust into a discharge pipe which may be fitted with a mouthpiece shaped like a funnel or a special spreading device. Mechanical devices are also employed to ensure regular feeding of the powder to the air blast. Manual dusters are similar in size and capacity to the manual sprayers and have a restricted usefulness. For farm work power machines are commonly used, particularly in the cotton fields of America. Like sprayers, these machines may be operated from the travelling wheel or driven by an internal combustion engine varying in size from 1 to 5 h.p. or so. For dusting large areas, aeroplanes have been used, and where large, uniform areas of a single crop require to be treated and the climatic conditions are suitable, the method may be regarded as established. (B. J. O.; H. G. R.)

SPREE (sprā), a river of Prussia, 227 m. in length, rising in Saxony, close to the Bohemian frontier, and flowing north past Bautzen, Spremberg and Kottbus, dividing between the first two towns for a time into two arms. Below Kottbus the river splits into a network of channels in the peculiar marshy region known as the Spreewald, then passes Fürstenwalde and Köpenick, threads Berlin in several arms and joins the Havel at Spandau. Over 100 m. of it are navigable and it is connected with neighbouring rivers by canals.

SPREEWALD, a district of Germany, in the province of Brandenburg, a marshy depression of the middle Spree valley, 106 sq.m. in extent, 27 m. long and varying from 1 to 7 m. in width. The river Spree, above Lübben splits into over two hundred arms, and in seasons of flood generally overflows considerable portions of this region. Part of the region is cultivated, part used as pasture land and wooded like a park especially in the lower districts. Fishing, cattle-breeding and the growing of vegetables, more particularly small pickling cucumbers, are the chief occupations of the people. In summer Spreewald is a popular resort of the Berlin people, and also in winter the district is largely visited by people bent on skating, sleighing and other winter pastimes.

SPREMBERG, a town in the Prussian province of Brandenburg, situated partly on an island in the river Spree and partly on the west bank, 76 m. S.E. of Berlin by the railway to Görlitz. Pop. (1925) 12,674. There are a pilgrimage chapel, dating from 1100 and a ducal château, built about the end of the 16th century (now utilized as Government offices). It carries on considerable manufactures of woollen cloth, as well as of bicycles, bricks and cigars.

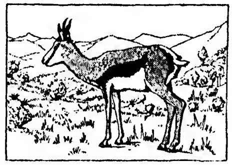
SPRENGEL, HERMANN JOHANN PHILIPP (1834–1906), German chemist, was born at Schillerslage, near Hanover, on Aug. 29, 1834, and educated in Hanover, and at the universities of Göttingen and Heidelberg. After three years as assistant in Oxford university chemical laboratory (1859–61), he engaged in research work at the Royal College of Chemistry in London. He was employed from 1865–1870 in Farmer's chemical works, and became a naturalized Englishman. For the rest of his life he was engaged on his own inventions and patents. His best known research, *On the Vacuum,* was published in 1865. In this paper he describes the vacuum pump known as the Sprengel pump. This pump opened up a large field for development in connection with the discharge tube, electric glow lamps, and numerous problems which required a vacuum for their elucidation. Sprengel devised the U-tube method of comparing densities of liquids. In 1873 Sprengel patented his device of introducing water in a fine spray instead of steam in sulphuric acid chambers. He was elected F.R.S. in 1878. He died in London on Jan. 14, 1906.

See obituary notice by Mesol in *Journal of the Chemical Society,* vol. 91 (1907).

SPRING, the act of springing, or leaping; hence applied in various senses: to the season of the year in which plant life begins to bud and shoot; to a source of water springing or welling up from below the surface of the earth (*see* WATER SUPPLY); or to an elastic or resilient body or contrivance for receiving and imparting mechanical power.

In architecture, the level of the plane at which an arch or vault begins to curve inward toward the centre; in an arch or vault whose curves are circular or segments of circles, the level of the centre points from which the circular curves are described.

SPRINGBUCK or **SPRINGBOK** (*Antidorcas euchore*), an aberrant South African gazelle inhabiting the country south of the Zambezi, but ranging northwestwards to Mossamedes. In the more settled parts of Cape Colony, the Transvaal, and the Orange Free State it now only exists within the enclosures of the large farms. Both sexes carry lyrate horns; the shoulder-height of an adult male is about 30in., and an average pair of horns measures 14in. along the curve; in the female the horns are more slender. The general colour above is reddish fawn, separated from the white of the underparts by a dark band on the flanks.



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

SPRINGBUCK OR SPRINGBOK (ANTIDORCAS EUCHORE), THE SOUTH AFRICAN GAZELLE

SPRINGER, the term given in architecture to the stone from which an arch springs (*see* ARCH); in some cases this is the stone resting on the impost or capital, the upper surface of which is a plane directed to the centre of the arch.

SPRINGFIELD, the capital city of Illinois, U.S.A., and the county seat of Sangamon county, on the Sangamon river, 100 m. N.N.E. of Saint Louis. It has a municipal airport; is on Federal highways 36 and 66; and is served by the Baltimore and Ohio, the Chicago and Alton, the Chicago and Illinois Midland, the Chicago, Springfield and St. Louis, the Illinois Central, the Illinois Traction (electric) and the Wabash railways. Pop. (1920) 59,183 (85% native white); estimated locally at 70,000 in 1928. The city has a level site of 9·72 square miles. The State capitol (begun in 1868 and occupied since 1876) is in the form of a Greek cross, with granite porticoes and a dome 361 ft. high. Facing it, in the same grounds, is the beautiful Centennial Memorial building (erected 1918–22, to mark the 100th anniversary of the admission of Illinois into the Union), which houses the State museum and the library of the State Historical Society, with its unequalled collection of Lincolniana. Across the street in one direction is the supreme court building (1905); in another, the State arsenal (1902–03); and not far away is the executive mansion (first occupied in 1856). The old capitol (begun in 1837 and occupied 1840–76) is now used as the county court-house. Near the heart of the city is Lincoln's home, the only one he ever owned, which he bought two years after his marriage and occupied until after his election to the Presidency. It is owned and maintained by the State. The Lincoln tomb and monument (a granite obelisk 121 ft. high over a mausoleum) stands on an eminence in Oak Ridge cemetery, north of the city. Springfield is full of spots associated with Lincoln: sites of his law-offices, boarding-houses and friends' homes; court-rooms where he practised; the old State-house, where he sat as representative, where he had headquarters during the campaign of 1860, and where his body lay in state in 1865; the Wabash freight station, where he said good-bye to his old friends on leaving for the White House; and many others. The city's parks contain 600 ac., and 2 m. N.E. are the State Fair grounds of 376 acres. In 1924 a comprehensive city plan was officially adopted, which will make Springfield a city of unusual beauty and distinction. It provides (among many other improvements) for the development of a capitol group (around the existing State buildings) and of a municipal group (around the Lincoln home, and including an open-air forum) and for parkways connecting the two with each other, with the Lincoln monument, with the proposed Union Station and with the principal parks. Since 1911 the city has had a commission form of government. The assessed valuation of property for 1927 was $30,164,100.

Springfield is in the heart of vast coal-fields. Several seams lie

under the city, one of which is worked, and about 5,000 miners make Springfield their home The Illinois oil-fields are only 150 m. distant Limestone, clay, oil shale, sand and gravel abound in the vicinity. The agricultural products within a 50 m. radius are valued at $190,000,000 annually. The city has a large wholesale and retail trade. Its manufacturing industries are numerous and diversified, with an output in 1925 valued at $26,587,661. Among the leading products are watches, agricultural implements, cast-iron pipe, tractors, road graders, electric meters, shoes and miners' lamps. Bank clearings in 1926 amounted to $147,300,000. The first settlement here was made in 1818 In 1821 the village was chosen to be the county seat, and was named Springfield In 1823 it was platted, and for a brief period was called Calhoun It was incorporated as a town in 1832 and chartered as a city in 1840 In 1837 it was made the State capital, in place of Vandalia, and the legislature met here in Dec. 1839 From Camp Yates (within the present city limits) Grant started on July 3, 1861, as colonel of a regiment of Illinois volunteers, for his service in the Civil War. Springfield was the birthplace of Nicholas Vachel Lindsay, and the early home of Edgar Lee Masters and Brand Whitlock

SPRINGFIELD, a city of Massachusetts, U.S A., at the intersection of Federal highways 5 and 20, on the east bank of the Connecticut river, 6 m from the southern boundary of the State; a port of entry and the county seat of Hampden county It is served by the Boston and Albany, the Boston and Maine and the New York, New Haven and Hartford railways Pop (1920) 129,614 (24% foreign-born white); 1928 local estimate 149,800, to which the contiguous cities and towns add over 75,000 Four bridges cross the river, including the Hampden county memorial bridge, a massive structure of steel and concrete, 80 ft. wide, built to commemorate the patriotic service of the county's citizens, and dedicated in 1923 The area of the city is 38 53 square miles It has many buildings of architectural importance, and since 1921 its development has been guided by an official planning board The new Union Railroad station, opened in 1926, is one of the most commodious and complete in New England The court-house, two churches and other buildings were designed by H H Richardson Facing a public park is the fine "Municipal Group" (designed by Pell and Corbett) which was dedicated in 1913, replacing the city hall erected in 1854 and completely destroyed by fire in 1905 It consists of twin buildings (one an auditorium and the other an administration building, each 115 ft wide, with a portico formed by ten Corinthian columns 41 ft high) on either side of a campanile 300 ft high, which contains a carillon of 12 bells The city's parks cover 1,268 acres. Forest park has an area of 757 ac, and includes a zoological garden and fine collections of lotus plants. The Art museum (1894–96) contains the valuable collections of George Walter Vincent Smith Near it is the Science museum (organized 1859); the city library, which has 325,000 volumes and an annual circulation of 10 volumes per caput of the entire population, and the William Pynchon memorial building (dedicated 1927), the home of the Connecticut Valley Historical Society. In Merrick park, adjoining the library, stands St Gaudens's statue of "The Puritan" The public-school system includes commercial, technical and classical high schools, a kindergarten training school, vocational and continuation schools. The American International college (1885) and the International Young Men's Christian Association college (1886) are in Springfield There are 77 churches in the city, and it is the see of a Roman Catholic and a Protestant Episcopal bishop The *Springfield Republican* (Independent), a morning newspaper established in 1824 by Samuel Bowles, is still owned by the Bowles family The city operates under a bicameral form of government. The assessed valuation for 1927 was $314,151,780.

There has been a U S arsenal in Springfield since the Revolution, when it was established by the Continental Congress; and an armory since 1794, when Congress authorized the building of the Government's first gun factory on a hill near the present railroad station which had been selected by Washington for the purpose in 1789. Here 800,000 of the famous Springfield muskets were made during the Civil War, and it is still the principal manufactory of small arms for the U S army The Smith and Wesson revolver factory, the Rolls-Royce automobile works, and a plant of the Westinghouse Electric and Manufacturing Company, are among the commercial manufacturing establishments of special interest. Springfield is noted for the diversity of its industries, which make nearly 1,500 different products, and employ chiefly skilled mechanics The aggregate output in 1926 (exclusive of the Government arsenal) was $113,990,400. The largest groups were electrical machinery, apparatus and supplies ($20,022,499), motor vehicles, bodies and parts ($12,168,826); foundry and machine shop products ($10,538,683), printing and publishing ($5,930,766) Springfield is the transportation centre, both by rail and by highway, of western Massachusetts, and a fine airport is under construction. The railroad terminal post-office at the Union station (one of the three maintained in New England) sorts and forwards over 1,200 carloads of mail each month A mail-order house sends some 500 tons of catalogues to Springfield by freight, to be mailed on to individual addresses The city's trade area has a population of 700,000 Two of the largest insurance companies of America have their home offices in Springfield. Bank clearings in 1927 amounted to $283,174,997

Springfield was founded in 1636 by a dozen families from Roxbury, under the leadership of William Pynchon (1590–1662), one of the original patentees of the Massachusetts Bay Colony, who left Roxbury because he was dissatisfied with its government, hoping to put his own theories into effect in a new colony The town was incorporated in 1641, and named after Pynchon's birthplace in Essex, England. For several years he ruled it with the power of an autocrat, but in 1652 he was removed from the magistracy in consequence of a tract in which he attacked the Calvinistic doctrine of the Atonement, and returned to England In King Phillip's War Springfield was a centre of hostilities After the establishment of the arsenal in 1777 it was an important military supply depot of the Continental army During Shays's Rebellion there was a riot here in Sept 1786, and on Jan 25, 1787, the insurgents, led by Shays, attacked the arsenal, but were dispersed by the militia Industrial development began with the establishment of the Government armory (1794), which brought in skilled workmen and attracted other enterprises In nine years the population increased 50%. A second impetus was given by the completion of the Boston and Albany railroad in 1839 By 1850 the town had a population of 11,766, and in 1852 it was chartered as a city.

SPRINGFIELD, a city of south-western Missouri, U S A, 200 m S E of Kansas City; the county seat of Greene county. It is on Federal highways 60, 65 and 66; has a municipal airport; and is served by the Frisco and the Missouri Pacific railways Pop 39,631 in 1920, 93% native white; estimated locally at 60,000 in 1928 The city has a beautiful location on the crest of the Ozark plateau, 1,300 ft above sea-level, and is surrounded by charming scenery frequently likened to Kent The region is rich in timber, and is famous for its poultry, dairy products, live stock, apples, strawberries, grapes, peaches and other fruits There are stone quarries and lead and zinc mines in the vicinity The city's manufacturing industries, which had an output valued at $19,071,888 in 1925, include extensive shops of the Frisco lines, the largest wagon factory west of the Mississippi, and a great variety of smaller plants Its jobbers and manufacturers do a combined business estimated at 25 to 30 million dollars annually Bank clearings amounted to $90,000,000 in 1926, and the city's assessed valuation for 1927 was $43,412,072 Springfield is the seat of Drury college (1873) and the South-west Missouri State Teachers college (1905). Adjoining each other are a National and a Confederate cemetery Springfield was founded about 1829; laid out in 1833; incorporated as a town in 1838 and again in 1846; and chartered as a city in 1847 It has a commission form of government At the opening of the Civil War Springfield was an important strategic point It was occupied alternately by Confederate and Union forces until the spring of 1862, after which the Unionists retained control. The battle of Wilson's Creek (Aug 10, 1861), 10 m. S. of the city, was one of the bloodiest engagements of the war The first railroad reached the city in 1870

SPRINGFIELD, a city of Ohio, U.S.A., the county seat of Clark county; 45 m. W.S.W. of Columbus, on Lagonda creek, near the Mad river. It is on Federal highway 40; has a municipal airport; and is served by the Big Four, the Detroit, Toledo and Ironton, the Erie, the Pennsylvania and electric railways, and by motor-bus and truck lines in all directions. Pop. (1920) 60,840 (12% negroes); 1928 estimate 73,000. The city occupies 11·7 sq.m. of undulating land, reaching an altitude of 980 feet. On hills north of the creek are Wittenberg college (Lutheran; founded 1845), and the State homes of three fraternal orders: the Knights of Pythias (opened 1894), the Masons (1895), and the Odd Fellows (1898). Immediately west of the college campus is beautiful Ferncliff cemetery, in which stands a Soldiers' monument on top of a prehistoric mound. The city's parks cover 250 acres. Springfield is an important manufacturing, publishing and horticultural centre. Its 33 greenhouses have 1,500,000 sq.ft. of glass and produce 4,800,000 rose-plants in a year. There is a peony farm of 70 ac., and nurseries for ornamental shrubbery. The aggregate output of the city's factories, 1927, was valued at $85,000,000. Among the leading products are agricultural implements, metallic caskets, motor trucks, water wheels, playground equipment, piano plates, gas and steam engines and small motors. Bank debits in 1927 aggregated $287,232,000, and the city's assessed valuation was $119,472,220. Since 1914 it has operated under a commission-manager form of government. In 1799 Simon Kenton and a small party from Kentucky built a fort and 14 cabins 3 or 4 m. W. of Springfield's present limits. Later in the year James Demint settled on a hill overlooking Lagonda creek. In 1801 he engaged a surveyor to plat a town here, and soon after this Kenton's settlement was abandoned. Trouble from the Indians threatened the new town until 1807, when peace was more firmly established at a council held on a neighbouring hill, where Tecumseh was the principal speaker. In 1818, when Clark county was erected, Springfield was made the county seat. It was incorporated as a town in 1827, and in 1850, when the population was 5,108, was chartered as a city.

SPRINGFIELD, a town of Windsor county, Vermont, U.S.A., and a village of the same name, 40 m. S.E. of Rutland, on the Black river, near the Connecticut; served by the Boston and Maine and the Springfield Terminal railways. Pop. (1920) 7,202. It is a manufacturing town, in a region of great natural beauty, with the falls of the Black river in the centre of the village. Springfield was settled about 1761. It was the first town in Vermont to adopt a manager form of government, which has been in operation since 1920.

SPRING-GUN, a device formerly in use against poachers and trespassers. Since 1827 spring-guns and all man-traps are illegal in England, except as a protection against burglars.

SPRING-RICE, SIR CECIL ARTHUR (1859–1918), British diplomatist, was born in London on Feb. 27, 1859, the second son of the Hon. Charles Spring-Rice (1819–70), and grandson of the 1st Baron Monteagle. Educated at Eton and Balliol college, Oxford, he entered the Foreign Office in 1882, becoming private secretary to Lord Granville in 1884 and précis writer to Lord Rosebery in 1885. He went to Washington as third secretary in 1886, and in 1895 proceeded to Berlin. In 1898 he become secretary at Teheran, and in 1901 British commissioner on the Caisse de la Dette in Cairo. In 1903 he went to St. Petersburg (Leningrad), first as secretary and later as councillor of embassy, remaining in Russia till the end of 1905. In 1906 he was sent to Persia as minister, having lately been created K.C.M.G. In 1908 he was created G.C.V.O. and went to Sweden as minister, and in 1912 was appointed ambassador to the United States. He died at Ottawa on his way home to England, Feb. 14, 1918.

See Sir V. Chirol, *Cecil Spring-Rice: In Memoriam* (1919).

SPRINGS are, in almost all cases, the natural overflow or point of escape from some underground reservoir of water. Their classification may be either according to the geological conditions governing the point of location, or according to the chemical composition of its waters. When an appreciable amount of chemical impurity is present they are usually termed "mineral springs."

The rocks which constitute the crust of the earth are either permeable or impermeable to water. During most seasons of the year, in temperate climates, a certain amount of rainfall soaks into any crust formed of permeable strata; the part absorbed may be the complete rainfall during winter months, when the air is saturated with moisture, or may fall to near zero during a dry summer, when all the rainfall is returned to the air as evaporation from the surface. That portion of the rainfall which soaks down below the level of plant-roots goes to replenish the underground reservoir. The shape of the reservoir varies indefinitely, according to the geological structure of the area; but it is only the shape of its water surface that concerns springs. This surface, known as the water-table, divides the fully saturated rocks from those which only hold moisture in their minute pores.

In an area of completely permeable rocks the springs issue at or near the valley bottoms; when, however, the district is made of alternating permeable and impermeable beds, each impermeable bed holds up water on its surface. If the strata are horizontal, small springs may be found all round the outcrops; but if they are tilted or folded the flow of the underground water will be towards the lowest point on the base of the permeable water-bearing bed. At this point the main spring for that local reservoir will be located.

In strata which are, in the main, impermeable, but somewhat brittle the presence of joints and cracks is of prime importance in determining the direction and amount of flow in the underground waters. In jointed rocks the rain-water may sink to great depths down one set of joints and rise again along a second, issuing at the surface as a warm or thermal spring; this is the probable cause of the hot springs at Bath. When a permeable bed and an impermeable one are brought into juxtaposition through faulting the flow of water in the permeable one is checked; but since faulting frequently shatters the rock it affords a plane of weakness along which the water will tend to flow. If the water is flowing under pressure due to an overlying impermeable cover, it may reach the surface as an "artesian spring." The water of artesian springs sometimes carries small particles of solid matter in suspension as well as salts in solution. The solid particles are dropped at the point of exit of the spring and may be cemented by the salts deposited from solution. When this takes place a mound is built up, from the summit of which the spring issues. Hence the "mound springs," such as are seen at their best in the great artesian basin of Australia.

Some of the largest springs issue from thick beds of massive limestone. This type of rock is usually well jointed and, being soluble in rain-water, the joints and marked bedding planes become enlarged by solution and the whole of the rainfall is absorbed in the mass of the rock and flows underground to issue as large springs. Frequently these springs yield a somewhat hard water of otherwise great purity.

Mineral Springs.—All springs containing noticeable quantities of salts in solution, other than the carbonate and sulphate of lime, are known by this name. The commonest minerals found are common salt, giving rise to "bitter springs"; and iron, sulphur, magnesia, etc., giving "medicinal" waters.

Thermal Springs.—The springs coming under this heading are derived from two sources. Firstly, meteoric waters which have penetrated down to considerable depths and rise again along well-defined fissures issuing as springs at the surface, but with the temperature of the rocks from which they have come; and, secondly, volcanic waters, either in the form of geysers or hot springs (*see* VOLCANO); in these the water may be either meteoric or in part, at any rate, juvenile—that is, water which is issuing at the surface for the first time. Most of these waters contain much mineral substance in solution, which is deposited on cooling and forms marked basins and terraces of sinter, such as the famous pink and white terraces of New Zealand.

(W. B. R. K.)

SPRINGTAIL, the common name of a group of small wingless insects forming the order Collembola, subclass *Apterygota* (*q.v.*). Many of them carry a pair of tail-like appendages near the extremity of the abdomen, which function as a springing

organ, hence the name.

SPRING VALLEY, a city of Bureau county, Illinois, U.S.A., on the north bank of the Illinois river, 104 m. S.W of Chicago. It is served by the Burlington Route, the Chicago and North Western, the Rock Island and the Illinois Traction (electric) railways. Pop 6,493 in 1920, 34% foreign-born white. It is a shipping point for coal, zinc, cement and farm products. The city was founded in 1885 and chartered in 1886.

SPRINKLER. The automatic sprinkler is a means of combating fire which has the approval of fire insurance companies, who often make a reduction in their premiums when it is employed The essence of the device is to arrange, under the ceiling of the building to be protected, a series of sprinklers which discharge water as soon as the temperature reaches a certain point The automatic release of the water is contrived by closing the valves of the sprinklers with fusible metal; the alloy employed being such as to fuse at a temperature of say 150° F. The sprinkler is so devised that the jet spreads the water in a shower, and the distance between the sprinklers is so arranged that every part of the floor is covered The sprinklers are connected with lines of pipes conveying the water under pressure In buildings where the water-pipes are likely to freeze, the ceiling connections are filled with air under pressure, so that when the valve opens through the metal fusing, the air escapes and the loss of pressure in the pipes works a lever that opens the valve of the water main (*See* also FIRE PREVENTION AND EXTINCTION.)

SPRUCE (*Picea*), an important genus of evergreen coniferous trees of the pine family (Pinaceae), called also spruce-fir, including about 40 species, natives of the cold and temperate regions of the Northern hemisphere They are pyramidal trees, with whorled branches; thin, scaly bark; linear, spirally-arranged leaves, each jointed near the stem on a separate woody base; and ovoid, oblong or cylindrical spreading cones, which become pendent when mature The spruces are readily distinguished from the pines by their solitary instead of fascicled leaves and from the firs in having pendent cones with persistent scales instead of upright cones with deciduous scales.

In an economic sense the most valuable species is the Norway spruce (*P excelsa* or *P Abies*), native to northern Europe and Asia and well known in plantations in the British Isles and eastern North America, though hardly attaining in cultivation the great height and noble form which it displays in its native woods In favourable situations it becomes the tallest and one of the stateliest of European trees, sometimes rising to a height of 170 ft. and attaining a trunk diameter of 5 to 6 ft. at the base It has a nearly straight, tapering trunk, throwing out in somewhat irregular whorls its widespreading branches densely clothed with dark clear green foliage. The boughs and their side branches, as they increase in length, have a tendency to droop, the lower tier, even in large trees, often sweeping the ground—a habit that gives a peculiarly picturesque effect The slender, sharp, slightly curved leaves are scattered thickly around the shoots; the upper ones pressed toward the stem, and the lower directed sideways, giving a somewhat flattened appearance to the individual sprays The cylindrical cones, 4 to 7 in long, grow chiefly at the ends of the upper branches

The Norway spruce is very widely distributed, growing on most of the mountain ranges of Europe from the Pyrenees northward and extending to 68° N, while in Asia it extends eastward to the Lena river and from the Altai mountains to beyond the arctic circle. On the Swiss Alps it is one of the most prevalent and striking of the forest trees In the lower districts of Sweden it is the predominant tree in most of the great forests; in Norway it constitutes a considerable part of the dense woods of the southern valleys, flourishing on mountain slopes up to 3,000 ft and clothing the shores of some of the fjords to the water's edge

While less valuable than the pine, the Norway spruce is an important timber tree When produced in close forests the white wood is of compact and even grain and suitable for a great variety of uses Immense quantities of spruce lumber are imported into Great Britain from north-western Europe. Great quantities also of younger trees are imported as poles, used for scaffolding, ladders and mining timber. In Norway the wood is very extensively made by hydro-electric power into wood pulp

As an ornamental tree Norway spruce has been commonly planted in Great Britain since about 1600 It is also grown as a "nurse" for other trees, for shelter for wall-fruit, for cover for game, and for small stakes and poles As a picturesque tree for park and other ornamental plantation it ranks among the best of the conifers, bearing the smoke of cities better than most of the fir-group, though subject to blight, which gives it an unhealthy appearance after a certain age. In North America the Norway spruce is extensively planted in the eastern States and Canada

In North America there are seven native species of spruce, of these, three are found in the eastern United States and Canada, two occur in the Rocky Mountain region and two are confined to the Pacific coast The white spruce (*P glauca* or *P alba*) is found from Maine to Minnesota northward to Labrador and Hudson bay and north-westward to Bering strait in Alaska. It grows to a height of 150 ft and a trunk diameter of 4 ft, with cylindrical cones 2 in long The white spruce is very valuable for lumber and especially for wood pulp, being the chief species utilized in the Canadian wood pulp industry The red spruce (*P rubra*) occurs from Nova Scotia to New York and southward in the mountains to Tennessee It is the dominant spruce in the Adirondack region, attaining a height of 60 to 100 ft, with brownish-red, ovoid cones, about 1¼ in long; it is extensively used for lumber and pulp wood The black or bog spruce (*P mariana*), native to swamps from Newfoundland to Alaska and southward to Virginia and Minnesota, commonly 20 to 30 ft but sometimes 90 ft. high, with small globose cones, is utilized for pulp wood and is the source of spruce gum

The Engelmann spruce (*P Engelmanni*), native to the Rocky Mountain region and extending westward to British Columbia and California, is a handsome tree of high altitudes It grows from 20 to 150 ft high, with slender branches and oval cones, sometimes 3 in. long The blue spruce (*P pungens*), native to the central Rocky Mountain region, is one of the most distinctive American species It grows from 80 to 150 ft high, with stiff, horizontal branches, and rigid, bluish-green to silver-white, spiny-tipped leaves, and oblong cones, 2½ to 4 in long Several varieties with characteristically blue foliage, as the well-known Koster blue spruce (var *Kosteriana*) are widely grown for ornament

The Sitka or tideland spruce (*P sitchensis*) occurs along the Pacific, extending about 50 m inland, from Kodiak island, Alaska, southward to northern California It is the most massive of the spruces, sometimes attaining a height of 190 ft and a basal trunk diameter of 20 ft, but it usually grows about 100 ft high, with a trunk 3 ft in diameter, with widely spreading, rigid branches, stiff, usually prickly-pointed leaves, and oblong cones 2 to 4 in in length The Sitka is a valuable timber tree, and is extensively lumbered The rare weeping spruce (*P Breweriana*), with hanging branches clothing the trunk to the ground and with the few horizontal branches decorated with cordlike hanging branchlets, is confined to the coastal mountains of northern California and adjacent Oregon

Among the various Old World spruces planted as ornamental trees are the Serbian spruce (*P Omarika*), the oriental spruce (*P orientalis*), of Asia Minor, the Himalayan spruce (*P. Smithiana*), the Alcock spruce (*P bicolor*) and the tiger-tail spruce (*P polita*), natives of Japan

SPRUE. Sprue is a disease of tropical and subtropical regions, and possibly cases arise in temperate climates also

Symptoms.—The symptoms usually begin with dyspepsia and irregularity of bowel action In a fully declared case the chief signs are the passage of bulky, frothy, pale porridge-like, stools, much flatulence and acidity, a sore, ulcerated mouth, a red, smooth and tender tongue, often with exquisitely painful ulcers on the fraenum and at the sides Loss of flesh is very rapid amounting

perhaps to 40lb. in two months. Cramps of the fingers and of the feet and calves are common in severe cases. Death occurs from exhaustion and intercurrent disease or, more usually, from intense anaemia, or rarely from perforation of an intestinal ulcer.

Treatment.—The treatment is rest in bed for a fortnight on a diet restricted to milk (increasing from 4 to $7\frac{1}{2}$ pints daily) together with calcium lactate (gr. 15 thrice daily) and extract of parathyroid (gr. 1/10th twice daily). The parathyroid *must* be free from admixture with thyroid (most preparations contain some of the latter) for if any of the latter be present, the symptoms become aggravated and palpitation and other indications of thyroid excess are superadded. With a pure preparation, however, the sprue symptoms improve within a fortnight, the ionic calcium increases to about 8 mg. %, the stools are reduced to one a day and the soreness of the mouth disappears. At the end of four weeks in favourable cases, the calcium lactate can be dropped and the parathyroid reduced to half doses. About this time the blood serum will show a normal calcium content, but the parathyroid extract should not be left off entirely for another three to four weeks. Should symptoms recur, a return for a few days to a simpler diet and to the parathyroid extract will restore health.

Many patients treated on these lines have returned to their duties abroad, many others have been treated in the tropics and have recovered. A few years ago the appearance of sprue meant immediate return to a temperate climate and prohibition of future residence in the tropics. (H. H. S.)

SPUR, an instrument attached to the heel of a rider's boot for the purpose of goading the horse. (A.S. *spura, spora,* related to *spornan, spurnan,* to kick, spurn.) The earliest form of the horseman's spur armed the heel with a single prick. In England the rowel spur is shown upon the first seal of Henry III., but it did not come into general use until the 14th century. In the 15th century spurs appear with very long shanks, to reach the horse's flank below the outstanding bards. After this time, and until the Restoration, they take many decorative forms, some of which remain in the great spurs worn by Mexican cavaliers. Gilded spurs were reckoned the badge of knighthood, and in the rare cases of ceremonial degradation they were hacked from the knight's heels by the cook's chopper.

In architecture, a spur (Fr. *griffe,* Ger. *Knoll*), is the ornament carved on the angles of the base of early columns; it consists of a projecting claw, which, emerging from the lower torus of the base, rests on the projecting angle of the square plinth; the earliest known example is in Diocletian's palace at Split (Spalato). In Romanesque work the oldest examples are those found on the bases in crypts, where they assumed various conventional forms; being, however, close to the eye, the spur soon developed into an elaborate leaf ornament, which in French 13th-century work and in the early English period is of great beauty.

SPURGE, a name applied to plants known botanically as Euphorbia (*q.v.*). The spurge-flax is *Daphne Mezereum,* and the spurge-laurel *Daphne Laureola,* both found in Great Britain.

SPURGEON, CHARLES HADDON (1834–1892), English Nonconformist divine, was born at Kelvedon, Essex, on June 19, 1834. He was the grandson of an Essex pastor, and son of John Spurgeon, Independent minister at Upper Street, Islington. He went to school at Colchester and Maidstone, and in 1849 he became usher at a school in Newmarket. He joined the Baptist communion in 1851, and in 1852 he became pastor of Waterbeach. His powers as a boy preacher became widely known, and at the close of 1853 he was "called" to New Park Street Chapel, Southwark. In a very few months' time the chapel was full to overflowing. Exeter Hall was used while a new chapel was being erected, but even that could not contain Spurgeon's hearers. The enlarged chapel at once proved too small for the crowds, and a huge tabernacle was projected in Newington Causeway. The Tabernacle was opened for service on March 25, 1861. Spurgeon preached at the Tabernacle on Sundays and Thursdays.

His Sunday sermons were sold literally by tons. They are models of Puritan exposition and of appeal through the emotions to the individual conscience, illuminated by frequent flashes of spontaneous and often highly unconventional humour. Collected as *The Tabernacle Pulpit,* the sermons form some fifty volumes. His book of sayings called *John Ploughman's Talks; or, Plain Advice for Plain People* (1869) found many readers. In the summer of 1864 a sermon which he preached on *Baptismal Regeneration* (a doctrine which he strenuously repudiated, maintaining that immersion was only an outward and visible sign of the inward conversion) led to a difference with the bulk of the Evangelical party, both Nonconformist and Anglican. Spurgeon maintained his ground, but in 1865 he withdrew from the Evangelical Alliance. Subsequently in 1887 his distrust of modern biblical criticism led to his withdrawing from the Baptist Union. He died at Mentone on Jan. 31, 1892.

See the *Life* by Schindler (1892) and Spurgeon's *Autobiography,* compiled by his widow and his private secretary from his diary, sermons, records and letters (1897–1900).

SPURN HEAD, foreland of the North Sea coast of Yorkshire, England, projecting across the mouth of the Humber. From Kilnsea it is 4 m. long but seldom exceeds 300 yd. wide. Formed of sand and shingle from the rapidly denuding Holderness coast to the north, it is only a few feet above sea-level.

SPY, a commune near Namur, Belgium. Here in 1886, in Betche aux Roches cavern, Maximin Lohest and Marcel de Puydt found two nearly perfect skeletons (man and woman) at the depth of 16 ft., with numerous implements of the early Aurignacian period. All the human remains are now in the Lohest Collection, Liége. The skulls are of the Neanderthal type.

See *L'Homme contemporain du mammouth à Spy* (Namur, 1887); G. de Mortillet, *Le Préhistorique* (1900); Sir A. Keith, *Antiquity of Man,* 2nd ed. (1925).

SPY. By The Hague Convention IV., 1907, a spy is a person who acting clandestinely or on false pretences obtains or endeavours to obtain information in the zone of operations of a belligerent, with the intention of communicating it to the hostile party (art. 29). If captured he is liable to be shot. A soldier not wearing a disguise is not a spy, though he may be found within the zone of the hostile army and though his object may be to obtain information; nor are soldiers or civilians spies who cross enemy lines openly carrying messages. This applies even to persons sent in balloons for the purpose of carrying despatches. A spy must not be "punished" without previous trial (art. 30), nor can he be treated as a spy if he is captured after he has rejoined his army. He must then be treated as an ordinary prisoner of war (art. 31).

The term "spy" is applied also to those who in time of peace secretly endeavour to obtain information concerning the forces, armaments, fortifications or defences of a country for the purpose of supplying it to another country.

SQUADRON, (1) a military term referring to the subdivision of a cavalry regiment, (2) a naval term referring to a detachment of war vessels, and (3) an air force term denoting a unit of a "group." Literally the term means a body of fighting men formed into a square. In 1656 the term was appropriated by horsemen but even in 1810 Scott in *The Lady of the Lake* refers to "squadrons tramping." The earliest use of the word in the military sense appears to be in 1562 and in 1581 Styward in *Martial Discipline* gives a clue to its origin: "The poore Swizers not being able to furnishe themselves with horse, were the first devisers of the pike and the squadrone," from which it is inferred that a body of pikemen formed into a square were employed on the flanks of a formation. This appears to be confirmed by Bullokar who wrote in 1616 that a squadron was a "square form in a battel." Previous to this, Sir John Smyth in 1590 refers to squadrons in reference to infantry, as also does Ward as late as 1639. Moryson in 1617 mentions "two squadrons of foot 250 men each." In 1702 a squadron of horse was anything between 100 and 200 men but by 1779 the number had been reduced to 80–120. At that date the squadron was composed of three complete troops. The Cavalry Regulations (British) of 1832 state that "Two or more squadrons compose a regiment." In the modern military sense a squadron is one of the principal units into which a regiment of cavalry is divided, corresponding to a company of infantry, the normal being three or four squadrons, sub-divided into

"troops." Squadrons are usually between 120 and 200 men. (*See* CAVALRY.)

In the naval sense the term refers to a part of a fleet usually commanded by a flag-officer, or it may be applied loosely to any number of vessels less than a whole fleet.

For its application to the air force *see* GROUP CAPTAIN and AIR FORCES.

In British military use, "squad" (a shortened form of "squadron") is used of any small detachment of men temporarily formed for drill or fatigue work or other duty. In the U.S. army, however, the squad is the basic infantry unit

SQUALL, the name given to any sudden large increase of wind velocity of less transient character than a "gust." A squall, usually lasting for some minutes at least, is attributable to meteorological causes, while gusts, which may succeed one another every few seconds, are the result of some mechanical interference with the direct flow of air, and are thus produced by turbulence A squall may include a succession of gusts A *coefficient of gustiness* has been determined for several stations by dividing the width of the ribbon (max veloc -min veloc) by the mean velocity These coefficients show a wide range

Pendennis castle (Falmouth) S. wind	Coefficient of gustiness			·25
Southport (Marsh side)	"	"	"	·3
Shoeburyness, E.N.E wind	"	"	"	·3
Holyhead (Salt island)	"	"	"	·5
Scilly (St. Mary's)	"	"	"	·5
Pendennis castle (Falmouth) W. wind	"	"	"	·5
Alnwick (roof of schoolhouse)	"	"	"	·8
Shoeburyness W. wind	"	"	"	·8
Kew observatory (roof)	"	"	"	1·0
Aberdeen (roof of King's college)	"	"	"	1·0

The most gusty exposure of the stations reporting to the Meteorological Office, is Dyce, near Aberdeen, with a coefficient of 1·3. At this station the mast of the tube-anemometer projects 15 ft above surrounding tree tops, which are particularly liable to produce turbulences.

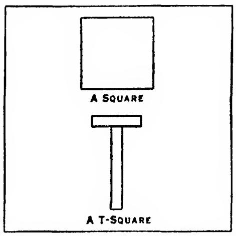
In the present state of anemometry it is difficult to give exact figures for the actual force of the wind during gusts, but 106·5 m p h were recorded at Pendennis castle on March 14, 1905 Squalls with velocities reaching 55 m p h are not uncommon, and the range of wind velocity during gusts in such a squall may be anything between 40 m p h and upwards of 100 m p h

The gradual veering of the westerly wind to the north-west is a common experience with squalls at Scilly. Changes in wind velocity are generally associated with some change in wind direction The increase of wind velocity occurs suddenly. At sea, the ruffling of the surface can be seen travelling over the water, and, on land, the approach of a violent squall is frequently marked by falling trees, etc

These phenomena are best exhibited in "line squalls." As the name suggests, a number of places arranged, roughly, in a continuous line, often hundreds of miles long, experience simultaneously a similar sequence of events The line of action advances with an approximately uniform speed across the country, and somewhat resembles the dash forward of the water of a broken wave. Its velocity can be determined easily from the time of occurrence of the various changes at different places. Though these changes normally occur at all places on the line, their intensity varies considerably; there is usually greater violence in the middle portion, and the disturbance becomes more intense as the whole line advances The course of events in typical line squalls has been worked out by R G K. Lempfert and Richard Corless The violent winds may therefore be attributed to the breakdown of the dynamical system under the stress of these local but sharp differences of pressure In this respect a V-shaped depression (*q v.*) may be regarded as a special case of a line squall in which the two currents are from approximately opposite directions, and the line of the trough which sweeps forward, keeping parallel to itself, represents the linear front. An example of a violent and destructive form of line squall is shown in the records for June 1, 1908. The Kew squall of wind which destroyed a number of the trees of Bushey avenue maintained its violence for a considerable period Many other famous line squalls, such as those of Feb 19, 1907, Oct 14, 1909, etc , have been examined (*See* Lempfert and Corless, *Line Squalls and Associated Phenomena* [Q J R Met Soc , vol xxxvi , 1910]) One of historic interest caused the loss of H M S "Eurydice" off the Isle of Wight on March 24, 1878 It was among the first to receive special attention, and was discussed by Abercromby in 1884 (*Quart. Journ. Roy Met. Soc* , x 172) and previously by Clement Ley (*Symon's Met. Mag* , April, 1878) The events of the World War deprived Norwegian meteorologists of weather telegrams from a considerable part of Europe, and, in consequence, they were compelled to base their forecasts on the intensive study of a small region This study resulted in much new light being thrown on the movements of air currents

In addition to the references given in the text, *see* Napier Shaw's *Life History of Surface Air Currents, Forecasting Weather* (1923), *The Air and its Ways* (1923), *Manual of Meteorology* (1919, 1926, 1928), V Bjerknes, *On the Dynamics of the Circular Vortex with Applications to the Atmosphere* (Christiania, 1921), together with various papers in the *Q J Met Soc* from 1910 onwards, J Bjerknes and H Solberg, *Life Cycle of Cyclones and the Polar Front Theory of Atmospheric Circulation* (Oslo, 1922)

SQUARE, a term variously used in mathematics, in technical work, and metaphorically In geometry it designates a rectilinear figure having four equal sides and four equal angles, the angles being right angles Such a figure is a special kind of rectangle (equilateral) and of parallelogram (equilateral and equiangular) It has four axes of symmetry and its two finite diagonals (as in the case of any rectangle) are equal If the side is s, the area is $s \times s$, or s^2, the name "s squared" being derived from this geometric relation Hence the analytic square is the product arising from multiplying any algebraic expression by itself, *e g* $(a+b)^2=a^2+2ab+b^2$ (*see* BINOMIAL FORMULA). The Latin writers called the side of a square its *latus* (side), and hence the square root of a number was often called the *latus*. In technical work the word is applied to instruments used for drawing or testing right angles, as in the case of the T-square here shown and the familiar carpenter's square.

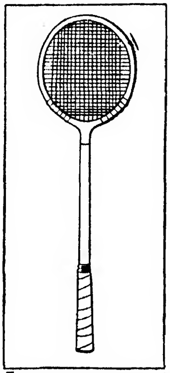


SQUASH RACKETS. A game played on exactly the same principle as rackets but in a smaller court and with a ball made of india-rubber The rules are in most particulars similar to rackets but the scoring is different In matches in England, hand-in only can win an ace The rubber is the best of five games of 9 up If, however, the score becomes 8 all, the player who reached 8 first has the option of a set to two In America a game consists of 15 points up, and an ace is scored for each rally irrespective of which player is serving, all matches being the best three out of five games The rotation of service in England is just as in rackets In the American game, the winner of one rally serves in the next

The Court and Implements.—Squash rackets can be played in courts of many sizes and descriptions both covered and uncovered with three or four walls and made of concrete or wood The first standardization of a court in England was made by the Tennis and Rackets Association in 1911 Shortly after the World War the Association issued revised standard dimensions and the great majority of British courts have been built to these dimensions since The standard court has four walls and can either be covered or uncovered. In length it is 32 ft and in breadth 21 ft. The front and side walls are 15 ft in height and the back wall is 7 ft in height The floor in a closed court should be made of wood; in an open court, of cement In a closed court the front wall should be of composition

The markings on the floor and front wall of the court are exactly similar to those in a racket court On the front wall, the top of the play line is 19 in from the floor and the service line

is 6 ft. from the floor. The short line is 14 ft. from the back wall. The service boxes are 5 ft. 3 in. square. In the space between the play-line and the floor is generally placed a strip of tin or some other metal in order to differentiate clearly in sound when the part of the front wall "in play" or "out of play" is hit. The lines on the wall and floor are painted red. Maple is considered a most suitable wood for the floor. The courts should be lighted from the roof, and nearly all modern courts, in addition to this lighting are fitted with electric light for evening play.



ENGLISH, BENT ASH FRAME, SQUASH RACKET

The American standard court is of different size to the English, being considerably narrower, 31 ft. by 18 ft. 6 in. The racket is precisely similar to the implement used in the game of rackets, only shorter in the handle. The ball is of black rubber. Many different forms of ball have been tried and formerly, when there were no standard courts, the ball which seemed best suited to the particular conditions was generally used. For the present standard English court the Association has adopted three standard balls. The ball used in America is larger than that in England.

Open competitions at squash rackets were unknown in England before the World War. In the years since, several have been started, the most important being the London inter-club tournament (teams of three) for the Bath Club cup; the amateur championship, the royal navy and army championships, and the ladies championships. The winners of the amateur championship have been:—April 1923, Capt. T. O. Jameson; Dec. 1923, Capt. Jameson; Dec. 1924, W. D. Macpherson; Jan. 1926, Capt. V. A. Cazalet; Dec. 1926, Capt. J. E. Tomkinson; Dec. 1927, Capt. V. A. Cazalet; Dec. 1928, W. D. Macpherson. Other leading British amateurs are H. W. Backhouse, Col. W. J. Bassett, C. Browning, R. G. de Quetteville, P. Q. Reiss, F. M. Strawson and G. N. Scott-Chad, the army champion. The prince of Wales is a very keen player and has competed several times in the amateur and army championships.

The British professional champion is Charles Read (Queen's Club) who defeated O. Johnson (R.A.C.) for the title in 1928. Leading lady players are Miss C. Fenwick, Miss Cave, Miss Joyce Cave and Miss S. Huntsman.

The development of the game in America has been even more rapid than in England. The large cities of the United States, particularly New York, Boston and Philadelphia, are amply supplied with courts and the game is also played with much keenness in Canada. Two British teams have visited America in the last few years and a United States team has also toured in England. Among leading American amateurs are M. Baker, W. Palmer Dixon and W. S. Wright. The champion in 1928 was H. N. Rawlins.

The French Squash Rackets Association was formed in 1926 and four courts were opened in Jan. 1927. Outside Europe and America courts are to be found in several parts of the British empire, especially in India and the far East. There are courts in New Zealand and in South Africa.

See E. H. Miles, *Racquets, Squash Tennis* (1902); C. Arnold, *The Game of Squash Rackets* (1926); E. B. Noel, *The Field Handbook of Squash Rackets* (1926). (E. B. N.)

SQUIB, a firework bursting with a flash and a clatter: hence a slight satirical composition put forth on an occasion, which should make a noise by its explosion, not by the possession of any permanent importance. Steele says, in the *Tatler*, that "squibs are those who in the common phrase of the world are call'd libellers, lampooners and pamphleteers," showing that in his time the satirist as well as the satire was called a squib. Swift speaks of the rapidity with which these little literary fireworks flew about, and was himself a proficient in the making of them. A good type of a squib is Gray's *Candidate*. (*See* LAMPOON.)

SQUID, the popular name given to a large number of cephalopod molluscs which include (*e.g.*) the common squids of the Atlantic (*Loligo, Ommastrephes*), the giant squids (*Architeuthis*) and the fire squids (*Lycoteuthis, Abralia*). They are exclusively marine animals of world-wide distribution and form an important part of the population of marine swimming and floating animals.

A typical squid, e.g., *Loligo vulgaris*, the common squid of the north-east Atlantic and Mediterranean, has an elongate slender body (visceral sac) edged by triangular fins, a short square head provided with well-developed eyes and ten arms. On the undersurface of the latter are arranged rows of suckers which are strengthened by tough horny rings. Two of the arms (tentacles) are longer and more mobile than the other eight (sessile arms) and the suckers are concentrated at the extremity as a "hand." The long tentacles are used for capturing prey, the sessile arms for transferring the latter to the mouth and grasping it while it is being crunched by the horny jaws which are situated around the mouth in the centre of the circlet of arms.

Situated within the muscular tissues of the "mantle" is a long horny structure, the "pen" or gladius. This is the rudiment of a shell and consists actually of a secondary growth (the proostracum) which has replaced the true shell-rudiment. In the genus *Ommastrephes* there is a vestige of the original shell.

The majority of the squids are active, highly mobile animals of aggressive habits and are probably all carnivorous.

Originally the squids were distributed among the two "tribes," Egopsida and Myopsida, of the ten-armed Cephalopoda (Decapoda). Recently, however, Naef and other students have proposed a more suitable classification of the Decapoda according to which the squids are all placed in a single sub-order, the Teuthoidea.

These forms are divisible into two groups originally called by C. Chun the *Oegopsida libera* and *Oegopsida consuta*. The first include the large, active and freely swimming forms (*Architeuthis, Loligo, Ommastrephes*, etc.). The second comprise a smaller assemblage of curious and highly modified forms which are less common than the Libera and are very largely planktonic. The distinction between these two groups is based on the mode of attachment of the ventral edge of the mantle to the head. In the Libera this attachment is effected by a stud and socket junction (*see* CEPHALOPODA) between the head and the edge of the mantle and can be freed from the head when necessary. In the Consuta the ventral edge of the mantle is permanently fixed to the head.

The Libera are represented by about 65 genera. Among them *Architeuthis* is the most striking on account of its size. The genus includes the largest living invertebrate animals, *Architeuthis princeps* of the north Atlantic attaining a maximum record length of 52 ft. (including the outstretched tentacles). *Sthenoteuthis*, a group of smaller forms, which attain a size of over seven feet, may be also reckoned "giant squids."

Another interesting group are the phosphorescent squids, *Nematolampas, Thaumatolampas* (*Lycoteuthis*) and *Abralia*, which bear light-organs in certain regions of the body (on the mantle, arms, inside the mantle-cavity and around the eyes). Certain of these animals when seen alive are very beautiful creatures.

Ommastrephes bartrami, the so-called "flying squid," is found throughout tropical and temperate seas. Its flight is, strictly speaking, a series of leaps across the surface of the sea which are often strong enough to land it on the deck of a ship. This feat is no doubt rendered easier in high seas.

The Consuta are mainly small animals. Their fins are largely reduced and the mantle is swollen and tun-like in *Cranchia, Bathothauma*, etc. In the latter, and in *Sandalops*, and *Corynomma* the arms are much reduced and the eyes are situated on stalks. Unlike the larger swimming squids these animals probably float largely at the mercy of the currents and are thus to be reckoned as "plankton." (*See* CEPHALOPODA.)

See G. Pfeffer, *Die Cephalopoden der Plankton-Expedition* (1912); C. Chun, *Wiss. Ergebn. d. Deutsche Tiefsee Expedn.* Bd. xviii. (1910). (G. C. R.)

SQUILL, the name under which the bulbous root of *Urginea Scilla* (family, Liliaceae) is used in medicine. The medicinal squill is a native of the countries bordering the Mediterranean,

and grows from the sea-level up to an elevation of 3,000ft The bulbs are globular and often weigh more than 4lb Two varieties are met with, the one having white and the other pink scales. They are collected in August, when leafless, the membranous outer scales being removed and the fleshy portion cut transversely into slices and dried in the sun.

Three pharmacopoeial preparations of this powerful drug are of importance. the syrup, composed of one part of squill, eight of dilute acetic acid and four of sugar, the *Pilula Ipecacuanhae cum Scilla,* in which ipecacuanha and opium are the chief constituents; and the tincture made by macerating one part of squill with five of alcohol. The drug is a cardiac stimulant Even in small doses it is a powerful expectorant and a fairly active diuretic. The drug must not be given alone, owing to its irritant action.

An allied species, *Urginea indica,* is used in India in the same manner as the European species The true squills are represented in Great Britain by two species, *Scilla autumnalis* and *S. verna.* These are confined to the sea-shore. There are 80 species or more in temperate regions of the old world Several species are grown in gardens, notably *S bifolia* and *S. sibirica,* originating from the Caucasus region and S W Asia. *S. nonscripta* or English bluebell and *S. hispanica* or Spanish bluebell are also widely cultivated

SQUINCH, in architecture, a general term for several means by which a square or polygonal room has its upper corners filled in to form a support for a dome: by corbelling out the courses of masonry, each course projecting slightly beyond the one below; by building one or more arches diagonally across the corner; by building in the corner a niche with a half dome at its head, or by filling the corner with a little conical vault which has an arch on its outer diagonal face and its apex in the corner The arched squinch seems to have been developed almost simultaneously by the Roman builders of the late imperial period and the Sassanians in Persia

Squinches are often found both in Romanesque and Mohammedan work In Italy the form is either the conical type as in the church of S. Ambrogio at Milan (crossing 11th or 12th century) or as a succession of arched rings as in the 13th century central tower of the abbey church at Chiaravalle Milanese; more complex forms, with niches and colonnettes are characteristic of the French Romanesque of Auvergne, as in the cathedral of Le Puy en Velay (late 11th and early 12th century); the allied churches of the south-west coast, such as St. Hilaire at Poitiers, use conical squinches of the Italian type. Mohammedan architecture, borrowing from the Sassanian precedent, makes great use of squinch forms, particularly in the Syrian, Egyptian and Moorish phases, the stalactite work, which is so marked a feature of later Muslim architecture, is, in essence, merely a decorative development of a combination of niche squinch forms In Gothic architecture squinch arches are frequently used on the insides of square towers to support octagonal spires (*See* BYZANTINE AND ROMANESQUE ARCHITECTURE; DOME, MOHAMMEDAN ARCHITECTURE; PENDENTIVE)

SQUIRE, JOHN COLLINGS (1884-), British man of letters, was born at Plymouth on April 2, 1884, and educated at Blundell's school, Tiverton, and St. John's college, Cambridge He then engaged in publishing and journalism, working for a time in the Press Gallery of the House of Commons. He became literary editor of *The New Statesman* in 1913, and was its acting editor in 1917–18 His early poems were issued as *Poems and Baudelaire Flowers* (1909), after which came some clever parodies, *Steps to Parnassus* (1913) and *Tricks of the Trade* (1917) Further poems included *The Lily of Malud* (1917), *The Birds* (1919), *The Moon* (1920), and *American Poems* (1923). In 1919 Squire founded *The London Mercury,* a monthly journal of literature and the arts, soon a distinctive stronghold in contemporary English criticism. He was also responsible for several volumes of reprinted essays and reviews (some originally under the pseudonym of "Solomon Eagle"), a number of anthologies of verse, and a book of short stories, *The Grub Street Nights Entertainments* (1924) (*See* ENGLISH LITERATURE.)

His later works include *The Comic Muse* (1925); *Poems in One Volume* (1926); *Life of the Mermaid* (1927); and an anthology entitled *The Cambridge Book of Lesser Poets* (1927), *See* I. A Williams, *J C. Squire* (*A Bibliography of His Works*) (1922)

SQUIRREL, the name of a red, bushy-tailed arboreal rodent, but also extended to include allied species Typical squirrels are found throughout the tropical and temperate regions except in Madagascar and Australia The common squirrel (*Sciurus vulgaris*) is found over the whole of Europe and North Asia, though showing great range of colouring in the various parts of its habitat. The ears are tufted, and the animal feeds largely on vegetables and fruits, varied with mice, small birds and eggs In North America this species is replaced by the grey *S carolinensis,* a larger and more powerful form, that has been introduced into Great Britain, where it has exterminated the native species in many places Squirrels vary in size from that of a mouse, as *Nannosciurus minutus* of West Africa, to that of a cat, as the black and yellow *Ratufa bicolor* of Malay In India the commonest species are the little striped palm squirrels, *Funambulus palmarum* and *F Pennanti,* the latter being the more northern species One oriental squirrel (*S caniceps*) assumes a definite breeding dress Squirrels form the family *Sciuridae* of the order Rodentia (*q.v.*) (*See* also GROUND-SQUIRREL, CHIPMUNK, SPINY SQUIRREL, GROOVE-TOOTHED SQUIRREL, FLYING-SQUIRREL)

THE AMERICAN GREY SQUIRREL. COMMON IN NORTH AMERICA

SQUIRREL MONKEY, a small golden-haired South American monkey, *Chrysothrix sciurea;* the name is also applied to the two other species of the genus, whose collective range extends from Costa Rica to Bolivia and Brazil The squirrel monkeys belong to the Cebinae (*see* CAPUCHIN-MONKEY), from the other members of which they differ by their practically non-prehensile tails, smaller size, their large eyes and the backward prolongation of the hinder part of the head (*See* PRIMATES)

SQUIRREL-TAIL GRASS (*Hordeum jubatum*), a name widely given in the United States to a species of wild barley, native to Europe, Asia and western North America and naturalized extensively in the eastern States and Canada, often becoming a troublesome weed, especially in alfalfa fields It is a perennial, with slender stems usually from 1 to 2½ ft high, bearing nodding, soft, brushlike, long-awned flowering spikes, from 2 to 4 in long and about as thick, whence the common name It is also known, locally as barley-grass, foxtail and tickle-grass

SQUIRREL TAIL GRASS

SRINAGAR, capital of the state of Kashmir, in Northern India, 5,250 ft above sea-level, on both banks of the river Jhelum, which winds through the city with an average width of 80 yds and is crossed by seven wooden bridges The houses occupy a length of about 3 m and a breadth of about 1½ m No two buildings are alike The curious grouping of the houses, the frail tenements of the poor, the substantial mansions of the wealthier, the curious carving of some, the balconies of others, the irregular embankment and the mountains in the background, form a quaint and picturesque spectacle Pop (1921), 141,736. The city is exposed to both fire and flood The artisans of Srinagar enjoy a high reputation. Unfortunately, the historic industry of shawl-weaving has been replaced by carpet manufacture Other industries are paper, leather, silver and copper ware, and wood-carving

SRIRANGAM, a town of British India, in Trichinopoly district, Madras presidency, 2 m N of Trichinopoly city Pop (1921), 23,152 It stands on an island of the same name, formed

by the bifurcation of the river Cauvery and by the channel of the Coleroon. The town is celebrated for its great temple, dedicated to Vishnu, composed of seven square enclosures, one within another, and 350 ft. distant from each other. Each enclosure has four gates with high towers, placed one in the centre of each side opposite to the four cardinal points. The outer wall of the temple is not less than 4 m. in circumference. It is a great place of pilgrimage.

STAAL, MARGUERITE JEANNE CORDIER DELAUNAY, Baronne de (1684–1750), French author, was born in Paris on Aug. 30, 1684, the daughter of a painter named Cordier. She adopted her mother's maiden name, Delaunay. She was educated at a convent at Evreux, later accompanying Madame de Grieu to the convent of St. Louis where the latter was appointed abbess. Mlle. Delaunay held a little salon there until 1710, and after the death of Mme. de Grieu entered the household of the duchesse du Maine at Sceaux. She helped her mistress to draw up the *Mémoire des princes légitimes,* demanding the meeting of the states-general. After a short imprisonment in the Bastille, on account of her implication in the Cellamare conspiracy (1718), she returned to the service of the duchess. She had had many admirers, and some serious passions, when, in 1735, being then over fifty, the duchess arranged her marriage with the Baron de Staal. She remained a member of the duchess's household, and became the friend and correspondent of Mme. du Deffant. She died at Gennevilliers on June 15, 1750.

Her *Mémoires* appeared about five years later, and have often been reprinted. In these memoirs the humours of the "court of Sceaux" are depicted as hardly any other society of the kind has ever been. "Dans cet art enjoué de raconter," says Sainte-Beuve, "Madame de Staal est classique."

Her *Mémoires* were edited (1877) by M. de Lescure, and translated by S. Bathurst (1877) and by C. H. Bell (1892). Mme. de Staal also left two excellent short comedies, performed at the court of Sceaux, and some letters.

STABAT MATER, famous mediaeval Latin hymn on the Crucifixion, which has enjoyed unexampled esteem throughout the ages, believed to have been written by Jacopone, a Franciscan monk of the 13th century. Though not originally intended for this purpose, it was early introduced into liturgical use and was adopted as one of the Sequences of the Roman missal in the 18th entury. Among the many settings of the poem by eminent mposers may be mentioned those of Josquin des Prés, Pales-a, Pergolesi, Haydn, Rossini, Verdi and Dvořák.

TABIAE, an ancient town of Campania, Italy, on the coast east extremity of the Gulf of Naples (mod. Castellammare bia). It was dependent upon Nuceria Alfaterna. In 89 taken and destroyed by Sulla, and its territory given eria as a reward for fidelity to Rome.

.DE, a town of Germany in the Prussian province of r, situated on the navigable Schwinge, 3½ m. above its ce with the Elbe, 20 m. W. of Hamburg on the railway ven. Pop. (1925) 11,992. The rise of Harburg has de- its former position as the chief port of Hanover.

, JOHANN PHILIPP KARL JOSEPH Austrian statesman, was ambassador in London fter some years of retirement he was entrusted mission to the Prussian court, where he endeav-o effect an alliance with Austria. He had greater ɔy at St. Petersburg (Leningrad), where he played ı the formation of the third coalition against Na-). Notwithstanding the failure of this alliance he reign minister, when he helped to prepare archduke a fresh trial of strength with France. In 1808 he the policy of procrastination, and with the help of ı hastened the outbreak of a new war. The unfortunate the campaign of 1809 compelled his resignation, but in was commissioned to negotiate the convention which verthrew Napoleon.

. Beer, *Zehn Jahre österreichischer Politik, 1801–1810* (Leipzig, *Die Finanzen Oesterreichs im 19 Jahrhundert* (Prague, 1877). o AUSTRIA.

STADIUM, the Latin form of a Greek word for a standard of length. A stade = 100 ὀργυιαί (about 6 ft. or one fathom) = 6 πλέθρα (100 Greek or about 101 English feet) = about 606 English feet, or about one-eighth of a Roman mile. The course for the foot-race at Olympia was exactly a stade in length, and thus the word for measurement became transferred first to the race and then to the place in which it was run. The modern word stadium is used for the permanent construction of an amphitheatre in which games and sports of various kinds can be conducted on a central space surrounded by continuous tiers of seats for the spectators. For a description of the Colosseum and other Roman amphitheatres, with illustrations, *see* AMPHITHEATRE.

The amphitheatre was a distinctively Roman building. The Greeks had their palaestra, their theatre and their circus. Upon the ruins of one of the most famous of these latter, the first "stadium," used for the first modern celebration of the revived Olympic games was built. Its original design was carried out in 330 B.C. in Athens. Its reconstruction by Herodes Atticus some 500 years later nearly exhausted the marble of the Pentelic quarries. It then fell gradually into decay. Excavations were begun by the king of Greece in 1870, and, in preparation for the Olympic games of 1896, this stadium was magnificently restored in white marble, with an arena seating 60,000 spectators, by the personal generosity of M. Averoff, a wealthy Greek merchant of Alexandria. It enjoys a setting which no other structure of the kind can ever equal, for above it are Lycabettus and the Acropolis. Unfortunately, as may be seen from the picture, the track contains corners at each end which make really high speed impossible and cannot now be altered, and the central enclosure is too narrow for the proper arrangement of the details of a modern Olympic programme. These are the results of taking the Greek instead of the Roman plan as the key of the design.

Though nothing can take from Athens the honour of having been the scene of the first meeting of the revival, it was clear that as soon as the Olympic games were fixed for London (in 1908) more care would have to be taken for the requirements of the modern athlete. The London stadium has remained the type of all subsequent constructions for successive Olympic meetings, and is also illustrated here, for it is still in use; and the consideration arises that, as the years pass, many such constructions, more or less permanent, will form an integral part of every great city in which the Olympic games have been or will be held. Those at Stockholm and Paris are also illustrated here. London's stadium at Shepherd's Bush could hold the whole external breadth of the Athenian marble building upon the 100 yd. of turf inside its running track, and the 235 yd. in length of that same turf is bigger than the external measurement of the Colosseum. The cinder-path all round the grass measures 1,760 ft., or exactly one-third of a mile. A concrete cycle-track runs all round and outside the cinder-path, and is embanked at each corner with solid slopes that form the inside of the wall containing a large public promenade all round the lowest tiers of seats. There are seats for more than 50,000 spectators, built up of steel girders and concrete, containing beneath the audience an enormous range of dressing rooms, committee rooms and offices. Two large portions of the seating area are completely sheltered from the weather; and opposite the royal box is a great concrete swimming bath, built just inside the running track, 109½ yd. long by 50 ft. wide, and a depth of 12 ft. in the middle, with movable raised platforms for high diving. The turf in the centre is 235 yd. long by 99 yd. broad, the cinder-path is 24 ft. wide, and the concrete cycle track is 35 ft. broad. The first stanchion was set on July 31, 1907; and the final cost was in the neighbourhood of £40,000. Even larger, and with far more architectural pretensions was the gigantic stadium erected after the World War at a cost of about £200,000 for the Empire Exhibition at Wembley, and that too is, of course, still in use.

After 1908, the next Olympic meeting was held in Stockholm, and the stadium erected by Sweden may be seen in the picture. It is also of a more permanent character than that at Shepherd's Bush; and though its cost (before the war) was nothing like that entailed at Wembley, it preserves all the essential features of London's Olympic building at Shepherd's Bush and combines with

STADIUMS OF EUROPE

The construction of the huge stadium at Athens in 1896 for the revival of the Olympic games, and the subsequent increase of interest in sports throughout Europe, have resulted in the building of several large stadiums and the reconstruction of others

1. Lyons Stadium in the old city of Lyons, France
2. Stadium built in London in 1908 for the holding of the Olympic games. There are seats for more than 50,000 spectators
3. Paris Colombe stadium, strictly practical design, constructed for the Olympic games of 1924
4. Ambitious stadium at White City, London, erected after the World War at a cost of about £200,000
5. "Les Arènes" ancient amphitheatre at Nimes, France. About 2,000 persons were living within its walls in 1809 when it was cleared by order of the prefect. It is now restored and used as a stadium. Photograph shows a bullfight in progress
6. Stockholm Stadium built for the fifth Olympiad in 1912, with a seating capacity of 15,000. Modeled after the London Olympic stadium with certain characteristics of Scandinavian architecture added

them certain typical and pleasing characteristics of Scandinavian architecture. The stadium built by France at Colombes for the games of 1924 is a strictly practical design, with arenas for lawn tennis, football and other games close beside it. The Amsterdam stadium was built for the games of 1928. (T. A. C.)

IN THE UNITED STATES

Athletics have come to form such an essential part of the curricula of modern universities that a general plan for these institutions can hardly be considered complete until suitable architectural provision has been made for the athletic activities The enormously increasing public interest in such games as football, baseball and track and field sports has given rise to a definite architectural problem which has found its most notable solutions in the United States. In America the stadia, comprising the field for games and seats for spectators, have grown steadily both in size and number, so that where there were only five of importance in 1913 there are now more than 30. Independently of the universities, several cities, recognizing the value of physical culture in a community, have provided stadia of great size, such as the Municipal stadium of Philadelphia, with its permanent seating capacity of 80,000 persons, the Los Angeles stadium, and the Chicago stadium with a permanent seating capacity of 55,000, capable of large increase.

Architecturally, the problem of the stadium is governed by the requirements of the sports practised within its walls Certain stadia, for instance, are designed for one sport only, such as football (*e g.*, Yale Bowl, stadium of the University of Michigan, etc.), and the baseball parks found throughout the United States; others for two sports, such as football and track racing, in which case the football field is surrounded by a quarter mile track provided with a straightaway for the dashes (*e g.*, those at Harvard and Ohio State universities and at Pasadena). Others are designed for three sports; viz , football, baseball and track racing (*e g*, universities of Pennsylvania, Pittsburgh, etc); this combination is difficult, owing to the wide difference between the shape of the football field and that of the baseball diamond, for if the seats for the spectators are placed close enough to the gridiron the arrangement will not accommodate the diamond.

The general shape of the stadium has been subject to much experiment and varies widely. Starting with the arrangement of two stands lying parallel to the side-lines of the football field, it has taken, successively, the U-shape, as in the stadia at Harvard and the universities of Pennsylvania and Kansas; the horse-shoe shape, as at Ohio State university; the ellipse of the old Roman amphitheatre, as in the Yale Bowl and at the University of Pittsburgh; and finally a rectangular shape with rounded corners. The last two types are suitable only for football. In several recent instances the early type of the two opposite spectators' stands has been revived, but it is so arranged that the larger number of seats are massed at the centres of the sidelines, on the theory that it is more important for the spectator to command an equal view of the goal lines than to be near the level of the field In this case, the stands take the form of a crescent, as at Cornell university, or of a trapezoid, as at Brown university, with about three times as many seats in the centre as at the ends

In elevation the forms of stadia vary even more; they range from an excavation in the ground, with the playing field below the level of the surrounding land, as at Yale and the University of Michigan, through the semi-buried type, such as the Philadelphia Municipal stadium, to a structure above ground enclosing a playing field at the ordinary level, as at Harvard and Princeton universities. This last type of construction, sometimes in two decks, as at the universities of Pennsylvania and Illinois and at the Ohio State university, is usually of reinforced concrete, with the double decks of steel. The design of the outer walls adopts suitable simplicity and is usually developed as a series of arcades, the concrete being sometimes faced with brick. The interest excited by the international tennis matches has necessitated the construction of stadia of a similar type, enclosing three courts (West Side tennis club, Forest Hills, N.Y.).

STAËL, MADAME DE. ANNE LOUISE GERMAINE NECKER, BARONNE DE STAËL-HOLSTEIN (1766–1817), French novelist and miscellaneous writer, was born at Paris on April 22, 1766. Her father was the famous financier Necker, her mother Suzanne Curchod, almost equally famous as the early love of Gibbon, as the wife of Necker himself, and as the mistress of one of the most popular salons of Paris. The future Mme de Staël was from her earliest years a romp, a coquette and passionately desirous of prominence and attention She was a plain child and a plainer woman, whose sole attractions were large eyes and a buxom figure. She is said to have written her father a letter on his famous *Compte-Rendu* and other matters when she was not fifteen, and to have injured her health by excessive study and intellectual excitement. There is no doubt that her father's dismissal, and the consequent removal of the family from the busy life of Paris, were beneficial to her. During part of the next few years they resided at Coppet, her father's estate on the Lake of Geneva, which she herself made famous They returned to Paris, or at least to its neighbourhood, in 1785, and Mlle Necker resumed literary work of a miscellaneous kind, including a novel, *Sophie*, printed in 1786, and a tragedy, *Jeanne Grey*, published in 1790. She married Eric Magnus, Baron of Stael-Holstein, who was first an attaché of the Swedish legation, and then minister For a great heiress and a very ambitious girl the marriage scarcely seemed brilliant, but the king of Sweden promised the ambassadorship for twelve years and a pension in case of its withdrawal, and the marriage took place on Jan. 14, 1786. The husband was thirty-seven, the wife twenty. Mme. de Staël was accused of extravagance, and after 11 years (1797) an amicable separation of goods was arranged There was no scandal between them, the baron obtained money and the lady obtained, as a guaranteed ambassadress of a foreign power of consideration, an established position. In 1788 she appeared as an author under her own name (*Sophie* had been already published, but anonymously) with some *Lettres sur J. J. Rousseau* She stood at this time for a mixture of Rousseauism and constitutionalism in politics. She visited Coppet once or twice, but for the most part in the early days of the revolutionary period she was in Paris taking an interest and, as she thought, a part in the councils and efforts of the Moderates. At last, the day before the September massacres, she fled from France, befriended at this critical juncture by Manuel and Tallien.

She betook herself to Coppet, and there gathered round her a considerable number of friends and fellow-refugees In 1793 she visited England, and established herself at Mickleham in Surrey as the centre of the Moderate Liberal emigrants—Talleyrand, Narbonne, Jaucourt and others. In the summer she returned to Coppet and wrote a pamphlet (*Réflexions sur le procès de la reine*) on the queen's execution The next year her mother died, and the fall of Robespierre opened the way back to Paris. M de Stael (whose mission had been in abeyance and himself in Holland for three years) was accredited to the French republic by the regent of Sweden; his wife reopened her salon and for a time was conspicuous in the motley and eccentric society of the Directory. She also published several small works, the chief being an essay *De l'Influence des passions* (1796), and another *De la Littérature considérée dans ses rapports avec les institutions sociales* (1800) It was during these years that Mme. de Staël was of chief political importance. Benjamin Constant, whom she first met at Coppet in 1794, had a very great influence over her, as in return she had over him. Both personal and political reasons threw her into opposition to Bonaparte. Her own preference for a moderate republic or a constitutional monarchy was quite sincere, and, even if it had not been so, her own character and Napoleon's were too much alike in some points to admit of their getting on together For some years, however, she was able to alternate between Coppet and Paris without difficulty, though not without knowing that the First Consul disliked her. In 1797 she, as above mentioned, separated formally from her husband In 1799 he was recalled by the king of Sweden, and in 1802 he died, duly attended by her They had three children: Auguste-Louis, Albert and Albertine, who married Victor, duc de Broglie

The exact date of the beginning of what Mme. de Staël's admirers call her duel with Napoleon is not easy to determine. Judging from the title of her book *Dix années d'exil*, it should be put at 1804; judging from the time at which it became pretty clear that the first man in France and she who wished to be the first woman in France were not likely to get on together, it might be put several years earlier. In 1802 she published the first of her really noteworthy books, the novel *Delphine*. In 1803 she returned to Paris. She was directed, by order of Napoleon, not to reside within forty leagues of Paris, and after considerable delay she set out, in company with Constant, by Metz and Frankfort to Weimar, and arrived there in December. There she stayed during the winter and then went to Berlin, where she made the acquaintance of August Wilhelm Schlegel, who afterwards became one of her intimates at Coppet. Thence she travelled to Vienna, where the news of her father's death (April 8) reached her.

She returned to Coppet, and found herself its wealthy and independent mistress, but her sorrow for her father was deep and certainly sincere. She spent the summer at the château with a brilliant company; in the autumn she journeyed to Italy accompanied by Schlegel and Sismondi, and there gathered the materials of her most famous work, *Corinne*. She returned in the summer of 1805, and spent nearly a year in writing *Corinne;* in 1806 she broke the decree of exile and lived for a time undisturbed near Paris. In 1807 *Corinne*, the first aesthetic romance not written in German, appeared. It is in fact, what it was described as being at the time of its appearance, "a picturesque tour couched in the form of a novel." The publication was taken as a reminder of her existence, and the police of the empire sent her back to Coppet. She stayed there as usual for the summer, and then set out once more for Germany. She was again at Coppet in the summer of 1808 (in which year Constant broke with her, subsequently marrying a German lady) and set to work at her book, *De l'Allemagne*, which occupied her for the next two years. She decided to publish the book in Paris. The submission to censorship which this entailed was sufficiently inconsistent and she wrote to the emperor one of the unfortunate letters, at once undignified and provoking, of which she had the secret. The reply to her letter was the condemnation of the whole edition of her book (ten thousand copies) as "not French," and her own exile from France. She retired again to Coppet, where she was not at first interfered with, and she found consolation in a young officer of Swiss origin named Rocca, twenty-three years her junior, whom she married privately in 1811.

The operations of the imperial police in regard to Mme. de Staël are rather obscure. She was at first left undisturbed, but by degrees the château itself became taboo, and her visitors found themselves punished heavily. Mathieu de Montmorency and Mme. Récamier were exiled for the crime of seeing her. On May 23, she left Coppet almost secretly, and journeyed by Bern, Innsbruck and Salzburg to Vienna. There she obtained an Austrian passport to the frontier, and, after some trouble, receiving a Russian passport in Galicia, she escaped from Napoleonic Europe.

She journeyed slowly through Russia and Finland to Sweden, making some stay at St. Petersburg, spent the winter in Stockholm, and then set out for England. Here she received a brilliant reception and was much lionized during the season of 1813. She published *De l'Allemagne* in the autumn, was saddened by the death of her second son Albert, who had entered the Swedish army and fell in a duel brought on by gambling, undertook her *Considérations sur la révolution française*, and when Louis XVIII. had been restored, returned to Paris. She was in Paris when the news of Napoleon's landing arrived and at once fled to Coppet, but a singular story, much discussed, is current of her having approved Napoleon's return. There is no direct evidence of it, but the conduct of her close ally Constant may be quoted in its support, and it is certain that she had no affection for the Bourbons. In October, after Waterloo, she set out for Italy, not only for the advantage of her own health but for that of her second husband, Rocca, who was dying of consumption. Her daughter married Duke Victor de Broglie on Feb. 20, 1816, at Pisa. The whole family returned to Coppet in June, and Byron now frequently visited Mme. de Staël there. Despite her increasing ill-health she returned to Paris for the winter of 1816–1817, and her salon was much frequented. She died on July 14, 1817.

Baron Auguste de Staël (d. 1827) edited the complete works of his mother in seventeen volumes (Paris, 1820–21), with a notice by Mme. Necker de Saussure, and the edition was afterwards republished in a compacter form, and, supplemented by some *Oeuvres inédites*, is still obtainable in three volumes, large 8vo (Didot). The *Considérations* and the *Dix années d'exil* had been published after Mme. de Staël's death. Some *Lettres inédites* to H. Meister were published in 1903. There is no recent reissue of the whole, and the minor works have not been reprinted, but *Corinne*, *Delphine* and *De l'Allemagne* are easily accessible in cheap and separate forms. Of separate works on Mme. de Staël, or rather on Coppet and its society, besides those of MM. Caro and Othenin d'Haussonville, may be mentioned the capital work of A. Sorel in the *Grands écrivains français*. In English there are biographies by A. Stevens (London, 1880), and Lady Blennerhasset (1889).

STAFF, MILITARY. It was not until the time of Cromwell and his "New Model Army" that we find anything comparable to our modern staff system. The organization of the staff of the "New Model Army" was based on that of the Brandenburg army of Gustavus Adolphus, the forerunner of the Prussian staff of later years. It bears little resemblance to the extensive and specialized staff organization of to-day, but was a great improvement on anything which had preceded it and was well suited to the small numbers and narrow battle fronts with which it had to deal. It consisted of a headquarters under a "Sergeant-Major-General" as chief of staff, and an administrative staff for each of the three commands, infantry, cavalry and train. It contained nothing corresponding to our present organization of a general staff responsible for the preparation of plans and the formulation of orders.

At the beginning of the 18th century and during the War of the Spanish Succession the increasing size of armies rendered it impossible for the commander-in-chief to exercise personal control over the whole of his forces. It was therefore found necessary to decentralize command by the grouping of units into permanent fighting formations called "brigades." At the same time the organization of the staff began to develop as a means of co-ordinating the action of these formations. Marlborough remodelled Cromwell's system and gave to his chief of staff, the "Quartermaster General," wider scope and greater responsibility than had his predecessor, the "Sergeant-Major-General," including administrative arrangements, reconnaissance and the collection of information. A large staff of aides-de-camp and gallopers was employed to convey orders on the battlefield, but these were not staff officers in the modern sense: they were rather the forerunners of our present signal service for the transmission of orders.

In 1760 during the Seven Years' War (1756–1763) Frederick the Great instituted the Prussian new academy and organized a body which he called the "Quartermaster General's Staff"; this latter was primarily responsible for the duties of preparing plans of fortifications and collating and publishing topographical information. The French, following the tendency to further decentralization of command, introduced the divisional organization, afterwards developed by both Wellington and Napoleon.

The Napoleonic Period.—The increase in the size of armies in the Napoleonic wars led to greater sub-division in organization and still wider decentralization of command. Wellington created a staff organization consisting of three branches, the Quartermaster General's dealing with administration, movements, fortification, topography and intelligence, the Military Secretary's dealing with correspondence of a confidential nature and the Adjutant General's dealing with personnel. The Quartermaster General still acted as chief of staff though as such his functions were limited, because Wellington, like Napoleon, was to a large extent his own chief of staff requiring no advice, but merely the machinery to convey orders and arrange routine.

The staff system used by Napoleon was designed by Louvois in 1687 and adapted in 1796 by Berthier, his chief of staff, to Napoleon's special requirements: it was organized as a writing staff, a fighting staff and a riding or liaison staff. Napoleon himself controlled the preparation of plans, reconnaissance and movements, and the conduct of operations; his autocratic military genius required only a confidential clerk of mechanical perfection and reliability, such as was Berthier, to complement it, and he had no use for a chief of staff, as we understand that term. Napoleon's orders were usually issued in the form of instructions which he expected his generals to carry out in the spirit of his intentions; his control was much less rigid than that of Wellington, whose problem was a more limited one and who was also characteristically more chary of decentralization. Napoleon's army, corps and divisional staffs, like Wellington's, consisted chiefly of aides-de-camp of various grades whose principal duty it was to convey orders on the battlefield and also between theatres of war: one such aide-de-camp rode with despatches from Salamanca to Moscow, a distance of over 2,000 m. They were sometimes given command of troops and appointed to govern provinces.

In the Prussian army, on the other hand, marked progress was made towards the realization of a modern staff system, following the defeat by Napoleon at Jena and the Treaty of Tilsit. Scharnhorst in his reorganization of Prussia's military forces was faced by a new problem; the total strength of these forces had been limited by Napoleon to 42,000 men and to circumvent this restriction it was necessary to resort to a short service system which provided large reserves of trained men for the expansion of the army in war. This new idea of a national militia required a highly trained staff to organize and train the man-power of the nation in peace and to mobilize it in war: with what success the demand was met is shown in the victories of 1864, 1866 and 1870 The Congress of Vienna in 1815 ended a period of 20 years of war and was followed by 40 years of peace in Europe, an era of military stagnation. In England no development resulted from the experience gained in continental campaigns and the country was glad to be quit of things military; in fact Wellington only preserved the nucleus of an army by keeping it abroad and out of sight as far as possible.

The Crimean War of 1854 found the British army, in consequence, unprepared and ill-organized. In 1857 a Council of Military Education was set up under the presidency of the commander-in-chief, the Duke of Cambridge; one of its first tasks was to study and define the qualifications necessary for a staff officer. This was followed by the creation of a Staff College with competitive examination as a condition of entrance, the first examination being held in February 1858 and the first course starting in April of that year.

Lessons of 1866 and 1870.—The successes of Prussia in the wars of 1866 and 1870 emphasized the importance of staff work The development begun under Scharnhorst and Gneisenau had been continued by Clausewitz, Roon and Von Moltke, the latter became Chief of Staff in 1858 and to him is mainly due the organization and training of the Prussian staff of 1866 and 1870. Scharnhorst's rule to the effect that staff officers must return periodically to regimental duty had been adhered to, and this, combined with a sound system of training, had produced a common doctrine throughout the army, which added greatly to its strength and efficiency in war through co-operation and economy of effort.

In France on the other hand there had been a reaction after the Napoleonic wars similar to that which had taken place in England, and the lessons of those wars were neglected. In 1818 an "École d'Etat-Major" was founded, but it provided instruction in the routine of staff duties only, combined with nothing of a higher nature. Officers entered it direct from St. Cyr and the Polytechnique (corresponding to the British Royal Military College and Royal Military Academy) and passed thence to the Staff Corps with which they remained for the rest of their service, a narrow-minded corps apart and out of touch with the troops. Another factor drawing French military thought in a false direction was the conquest of Algeria begun in 1830, a small war against a savage enemy This kind of fighting came to be considered as typical of all war and the mental outlook and training of the French commanders and staff officers were restricted accordingly. Thus Napoleon had organized corps and grouped corps into an army, but in 1870 the idea of an army did not exist Napoleon before the battle of Jena in 1806 had moved six corps by three roads at twenty miles a day, billeting in depth; but in 1870 the French corps marched as in savage warfare, closing up on the head at the end of the march, the rate of movement being reduced in consequence to eight miles a day. But fortunately for France there were young men of ability and foresight serving in the army of 1870 and they determined to discover the real cause of the disaster These men were Bonnal and Lanrezac serving as subalterns, Foch a private in the ranks, and Maillard, later famous for his tactical teaching. They studied deeply the campaigns of Napoleon, and showed how he had applied the principles of war. In 1880 the "Corps d'Etat-Major" was abolished and the "École de Guerre" or Staff College was founded, Maillard being the first professor of strategy. It was recognized that the successes achieved by the Prussians in the wars of 1866 and 1870 had been largely due to their staff organization and training; this led to the adoption, during the last quarter of the nineteenth century, of similar systems by all the military powers except Great Britain and the United States of America

British Reorganization.—In 1895 the Duke of Cambridge resigned his post of commander-in-chief, and the concentration of military responsibility vested in him was dissipated, leaving the new commander-in-chief, Lord Wolseley, with little authority beyond what was involved in the vague term "general supervision" The supreme management of the affairs of the army devolved upon the Secretary of State for War assisted by several officers of equal status *inter se* But in 1896 a step forward was taken by the formation of the Defence Committee of the Cabinet, which later became the Committee of Imperial Defence.

After the South African war a special committee, known as the "War Office Reconstitution Committee" was set up in 1903 with Lord Esher in the chair This committee found that the lack of a trained general staff and the fact that some of the most important duties of such a staff were not assigned to any body of officers gravely prejudiced the conduct of operations in South Africa, and that it therefore attached extreme importance to the constitution of a general staff

The Committee also advocated the abolition of the office of commander-in-chief instituted by the Duke of York in 1795 and its replacement by a Chief of the General Staff and an Army Council, whose function it would be to control and administer the army in accordance with the policy of the government and to act in an advisory capacity to the Secretary of State for War These recommendations were adopted, and in February 1904 Lord Roberts, the commander-in-chief, retired and the new Army Council came into being. Its first task was the creation of a general staff charged with the duties of advising on the strategical distribution of the army, supervising its training and preparation for war, collecting and collating military intelligence; directing the general policy of the army and securing continuity of action in the execution of that policy And so for the first time in British military history the staff became a well balanced organization with two clearly defined functions: on the one side the preparation of plans, training and conduct of operations dealt with by the general staff, and on the other the supply of personnel and material, medical arrangements, transportation and quartering dealt with by the administrative staff which also controls the necessary services such as the R A S.C, ordnance, medical and veterinary services. But it is important to note that, although the work is divided into separate branches, there is but one staff with a single purpose, namely to assist the commander when framing his plan and the troops and services in carrying it out The division of staff duties under the two main heads of operations and administration is now the key-note of the British system

In 1904, in accordance with another and very important recommendation of the Esher Committee, the Defence Committee of the Cabinet was reconstituted as the Committee of Imperial

Defence, whose function it was to act in an advisory capacity to the government, ensure continuity of policy and co-ordinate the work of all government departments concerned in national defence. Prior to the formation of the Committee of Imperial Defence there existed no precedent for the formation of a council of war, or any standing advisory body to assist the Cabinet in time of peace in matters of national defence. An Imperial Defence Conference was held in 1909 at which it was decided that the general staff at the War Office should be made responsible for advising the government on all matters connected with the defence and military preparation of the Empire as a whole; the Chief of the General Staff became Chief of the Imperial General Staff responsible for the preparation of plans and estimates of the imperial forces required to give effect to these plans.

Following the report of the Esher Committee the staff system was modernized and developed, with the result that at the outbreak of the World War the task of mobilizing the expeditionary force and despatching it to France was carried out with extraordinary smoothness and efficiency. In the field also the new system stood the test and strain of war very well in spite of the difficulty of meeting the demands of the largely expanded army. But, as regards the higher direction of the war, matters did not proceed so smoothly. In its conception in 1904 the Imperial General Staff was designed to have responsibility for providing the government with advice; it was however at first mainly occupied in shaping a policy for the direction of affairs within the army itself and thus failed to study at all adequately its main function in relation to the supreme direction of imperial military policy.

Lessons of the World War.—The resultant lack of coordination as between policy and strategy led to great wastage of effort and man-power, and resort to improvisation in the machinery for the direction of the war. To avoid similar mistakes in future it is necessary that there should be a clear definition and understanding of the respective functions of the statesman and his military advisers. Since the Cabinet alone is qualified to coordinate and direct the whole strength of the nation in war, it follows that it must exercise the supreme control. The duty of the head of the government is to formulate policy and to ensure that that policy is suited to available means. The duties of the chiefs of the navy, army and air force are to prepare plans for the execution of the policy of the government, to act as professional advisers and to issue the orders required for carrying out the accepted plan; whilst the co-ordination of plans is now provided for in the Chiefs of Staff Sub-Committee of the Committee of Imperial Defence.

Germany also experienced serious difficulties in regard to the supreme direction of the war owing to the fact that the Kaiser was the nominal commander-in-chief of the army and as such took the field. The result of this was that the machinery for the central control of the war became situated at general headquarters on the western front where it could not work effectively in cooperation with the government, whilst it necessitated headquarters themselves being placed too far from the front to be able to control operations. The growth of armies had long rendered the government of a state, whether vested in a sovereign or exercised through other channels, incapable of direct command and even of formulating a military policy; hence the necessity for a professional head of the military executive who could function for the government in adapting the military to the national policy. So long as war was confined to a single theatre and small armies, the professional head might also exercise command in the field, as did von Moltke in practice in 1866 and 1870. When, however, war is waged simultaneously in more than one theatre and by nations in arms, a further expansion in organization is essential.

The study of the broad aspects of the German staff organization and its functions during the World War leads to the following conclusions. The central government must have in immediate touch with it a professional military executive responsible for controlling military policy both as regards plans and the provision of means in men and material to execute those plans. This military executive must implement a policy formulated on the advice of a single individual, whether he be called chief of staff or commander-in-chief. But in each theatre of war there must be a separate commander-in-chief who is in executive control of such forces as are placed at his disposal, and who regulates his action in accordance with the instructions he receives from the central authority. The staff of the commander-in-chief in each theatre of war must be organized in branches corresponding to those of the central staff organization and in direct touch with them in so far as this does not militate against the control exercised by the commander.

Special British Problems.—Continental nations have very clearly defined problems to deal with and can therefore prepare detailed plans and an organization to execute them. With the British, however, it is not possible to do more than provide for the detailed organization of the central authority at home which exists in peace and should not require any change in war; the detailed composition and organization of command and staff in the field must be dependent upon the particular conditions of operations which cannot usually be foreseen. Consequently the system must be such as to be easily adaptable to whatever demands may be made upon it.

That the organization of the British staff in the field during the World War was sound in principle is shown by the fact that it was not necessary to make any material changes in spite of the enormous expansion of the army and the imposition of new duties through the remarkable progress of modern science as applied to war. This organization consisted at general headquarters of a staff divided into three branches, the general staff branch under a chief of the general staff dealing with operations, intelligence and training, the Adjutant-General's branch dealing with personnel, discipline and the medical service and the Quartermaster-General's branch dealing with supply and transport. Each of these principal staff officers had the right of direct access to the commander-in-chief in all matters appertaining to his branch, whilst the chief of the general staff was responsible for co-ordinating the work of the three branches in accordance with the policy laid down by the commander-in-chief. The same system was applied in lower formations except that the functions of the Adjutant-General and the Quartermaster-General were combined in one staff officer.

The alternative to this system is that adopted in other armies including those of the United States of America, France, Germany and Japan, namely a chief of staff responsible not only for co-ordination of the work of the various branches of the staff, but also for its execution. The objections to this system are that the chief of staff becomes a "bottle-neck" prejudicing the right of access to the commander of branches and departments and forced to devote a great deal of his time and attention to administration at the expense of operations and training. The advantages claimed for it are that the commander-in-chief has only one staff officer with whom he deals direct, instead of three or four, as in the British system; and, since the army cannot fight without supplies, that the chief of staff is responsible for both operations and maintenance; in practice, however, there is an inevitable tendency for him to become overloaded with detail.

It will be seen therefore that there is a fundamental difference between the British staff system and that of other armies; in the former, operations and administration are dealt with separately, whereas in the latter they are combined under a chief of staff. Judged by experience, the British system by which the senior staff officer in each branch has direct access to the commander and the senior general staff officer is responsible only for coordination of the work and not for its execution, is the one best suited to British requirements and temperament; and that it can be applied successfully was amply proved in the World War; where failures occurred, as in Mesopotamia and Gallipoli, they were due to non-observance of the principles of staff organization rather than to any fault in the scheme of organization itself.

Mainly as a result of developments in mechanization since the war it has been decided to effect certain changes in the British staff organization at general headquarters. This will now consist of a Chief of the General Staff, a deputy Adjutant-General, deputy

Quartermaster General and deputy Master General of the Ordnance. Thus there will be now four principal staff officers instead of three, and each, as formerly, has the right of direct access to the commander-in-chief in matters relating to the respective branches, the work of the staff as a whole being co-ordinated, as necessary, by a deputy Chief of the General Staff. The cause and effect of these changes are briefly as follows The four military members of the Army Council are the Chief of the Imperial Staff, the Adjutant General, Quartermaster General and Master General of the Ordnance· of these the Chief of the Imperial General Staff has the peculiar responsibility of adviser to His Majesty's Government in all matters affecting the military policy of the British Empire, and in this capacity he cannot be represented at general headquarters in the field, there is therefore a Chief of the General Staff at these headquarters, and the other three military members are represented by deputies, who deal directly with their chiefs on the Army Council in departmental matters The addition of a deputy Master General of the Ordnance is principally due to the demands of mechanization. At the War Office responsibilities in connection with maintenance are divided between the Quartermaster General and the Master General of the Ordnance· in the field, however, there has hitherto been no representative of the latter at general headquarters consequently the whole responsibility for maintenance has rested with the Quartermaster General in addition to that of movement Though this centralization has certain advantages, it now tends through the increasing demands of mechanization to exceed the scope of a single principal staff officer and his branch A further advantage of having a representative of the Master General of the Ordnance at general headquarters in war is that he acts as the link between the field army and the Ministry of Munitions or other body dealing with research and experiment at home Following on these changes a certain reallotment of duties as between the Quartermaster General and the Master General of Ordnance at the War Office has been effected The re-allotment of duties leaves the control of all transport by sea, rail, road and inland water under the Quartermaster General The division of responsibility in the matter of maintenance places under the Quartermaster General the provision of accommodation, remounts, supplies of food, forage, fuel and petrol, and responsibility for all duties in connection with engineer services and barrack construction; while the Master General of Ordnance is responsible for providing clothing and equipment, guns, ammunition and vehicles of all types

The air forces of the Great Powers, except Britain, France and Italy, are an integral part of the navy and the army and are administered as an arm of the service and not as a separate service; therefore there is no special air staff organization In the British air force the work of the staff is controlled by three principal staff officers dealing respectively with air, personnel and equipment. Each of these officers has the right of direct access to the commander, the co-ordination of their work being vested in the senior air staff officer The staff is assisted by advisers, whose specialized technical knowledge is at their disposal

THE UNITED STATES

The President, by virtue of his office being commander-in-chief of the Army of the United States, exercises control thereof through the secretary of War, who, with the aid and advice of the chief of staff, is responsible for the efficiency of the military establishment. Under the secretary of War, command is exercised by corps area and department commanders, commanders of independent activities and commanders of the various tactical units The staff does not exercise command. While the army had no general staff prior to 1903, it has invariably had an administrative staff, whose strength and composition has varied according to needs. Under the secretary of War and the various commanders, the administrative staff has performed staff duties pertaining to administration, inspection, discipline, supply, pay, medical attendance and sanitation

Under the National Defence Act of 1920, the administrative staff corps and departments authorized are The adjutant general's department, the inspector general's department, the judge advocate general's department, the quartermaster corps, the finance department, the medical department, the ordnance department and the chemical warfare service The headquarters of each corps area or territorial department and of each tactical unit down to include the division is provided with representatives of each of the staff corps or departments named At the headquarters of stations and at the headquarters of tactical units below the division where representatives of the various staff corps or departments are not provided, other staff officers or officers of the line detailed for that purpose perform the necessary administrative staff duties.

Prior to 1903, the army was commanded, under the secretary of War, by the commanding general of the army His command did not extend to the supply departments, and the chief of each supply department reported directly to the secretary of War There was no officer nor body of officers charged with co-ordinating the work of the staff departments with the work of the line, nor was there any officer or body of officers whose principal duty it was to prepare plans for the national defence The necessity for such a body of officers, charged primarily with co-ordinating and planning, was clearly demonstrated during the Spanish-American War, and, as a result, the act of Feb 14, 1903, authorized the War Department general staff. Under its initial organization, it consisted of three divisions From 1903 until 1917, as the result of the limited experience which could be gained in peace-time, many changes were made in the organization during its process of development During the World War, as necessity demanded, many further changes were made in it, and the present general staff, organized under the provisions of the National Defence Act of 1920, is the result of that experience

The National Defence Act prescribes that the duties of the War Department general staff shall be to prepare plans for national defence and the use of the military forces for that purpose, both separately and in conjunction with the naval forces, and for the mobilization of the manhood of the nation and its material resources in an emergency, to investigate and report upon questions affecting the efficiency of the Army of the United States, and its preparedness for military operations; and to render professional aid and assistance to the secretary of War and the chief of staff. It is the agency for preparing the plans and policies under which the administrative and command agencies operate

The chief of staff, the deputy chief of staff, 5 assistant chiefs of staff, and 87 other officers, compose the War Department general staff over which the chief of staff presides He prepares the necessary plans for the use of the military forces for national defence and upon approval of such plans by the secretary of War, is charged with the supervision necessary to make them effective Each assistant chief of staff is the head of a division and has authority to make decisions for the secretary of War within certain limitations The personnel division (G-1) is charged with those duties which relate to the personnel of the army as individuals The military intelligence division (G-2) is charged with those duties which relate to the collection, the evaluation and the dissemination of military information The operations and training division (G-3) is charged with those duties which relate to the organization, training and operation of the army. The supply division (G-4) is charged with those duties which relate to the supply of the army The war plans division is charged with those duties which relate to the formulation of plans for use in the theatre of war of the military forces, separately or in conjunction with the naval forces.

The organization of the War Department general staff is such

that some of the officers who had been engaged in the formulation and preparation of plans of operation could take the field in time of war and could be utilized as general staff officers with troops to supervise the execution of these plans. This could be accomplished without disrupting the entire staff, as was done when the United States first entered the World War.

As distinguished from the War Department general staff, the National Defence Act prescribes that the general staff with troops shall perform the general staff duties of the headquarters of territorial departments, armies, army corps, divisions and brigades, and shall render professional aid and assistance to the general officers over them. It shall also act as their agents in harmonizing the plans, duties and operations of the various organizations and services under their jurisdiction, in preparing and supervising detailed instructions for the execution of the plans of the commanding generals. At the headquarters of each corps area and department and of each tactical unit authorized to have a general staff, the general staff is divided into four sections corresponding to the first four divisions of the War Department general staff.

(C. P. SU.)

STAFF, NAVAL. All the principal navies of to-day have a body of officers specially charged with war plans, operations, intelligence and the policy to be adopted in such professional matters as training, design of warships, naval aircraft and armament.

In the British Navy the Naval Staff at the Admiralty (*q.v.*) consists of the Chief of the Naval Staff, who is the First Sea Lord, the Deputy Chief of the Naval Staff, the Assistant Chief of the Naval Staff, together with the directors and officers of the various staff divisions. The latter include: operations, plans, intelligence, trade, gunnery, torpedo, training and staff duties, together with the naval air and tactical sections.

At sea, the commander-in-chief has a staff which includes a chief of staff, captain of the fleet, staff officers for operations, gunnery, torpedo, signals, wireless, intelligence, aviation, physical training, engineering, accountancy, medical duties and education. Flag officers in command of divisions or squadrons have a smaller number of staff officers, certain duties being combined or omitted where they are carried out in the fleet flagship. In addition every admiral has a personal staff consisting of his flag lieutenant (A.D.C.) and secretary.

Previous to the World War, although Britain had the largest and most powerful navy of any nation and in consequence was regarded as being a leader in naval enterprise, both the Admiralty and the fleet were singularly deficient in a properly organised staff. This may be attributed in part to the influence of traditions emanating from the days of the sailing navy, when communications were slow and primitive and once an admiral was out of sight of land he was thrown entirely on his own resources and had to act as circumstances arose or as emergency rendered necessary.

Even in more modern times, unfortunately, a school of thought developed which was definitely antagonistic to the idea of a naval staff. As late as the outbreak of the World War there were to be found a number of flag officers of distinction who resented the suggestion that they could be assisted in the execution of their command by comparatively young officers who, it seemed to them, would be usurping some of the functions of an admiral.

The influence of this reactionary school of thought continued to dominate Admiralty policy in this matter until, in 1911, the matter was brought to a head by the discovery that the Admiralty had one lot of war plans and the War Office another, and that these were by no means attuned. In 1912, Winston Churchill, as First Lord, initiated the principle of a Naval Staff. The resignation of the then First Sea Lord, Admiral of the Fleet Sir Arthur Wilson followed. Incidentally this marked the end of the "one-man" régime. With his retirement, too, may be said to have disappeared the habit of intense secrecy, a habit which led to most dangerous ignorance of strategical plans and tactical intentions in the minds of those not in the innermost confidence of the high command.

In spite of the sound decision to create a naval staff, it could not be said that great progress had been made in this direction by August 1914. True there was a Chief of the Naval Staff, a Director of Operations, and from time to time, if the need arose, additional staff appointments were created, while at sea the commander-in-chief of the Grand Fleet and other admirals in important commands, had a number of officers on their staffs. But for the most part the officers in these Admiralty Departments and on the admirals' staffs at sea were untrained in staff work, while many flag officers, both ashore and afloat, had never learned how to use a staff. With traditional adaptability and with that ability to extemporise which comes from sea training, the navy met each and every emergency as it arose, sometimes successfully, but sometimes buying experience at great cost, until ultimately victory came. But one of the outstanding lessons of the World War from a naval point of view was the necessity for not only training officers to fill numerous minor staff appointments, but also to educate those destined for higher command in the use of a staff.

By 1928 the Naval Staff College at Greenwich was engaged in turning out year by year officers trained for duty on admirals' staffs at sea or for the lower staff appointments at the Admiralty, and already this training is beginning to make itself felt as Staff College graduates are beginning to reach more senior rank.

The old antipathy towards a naval staff has died down, and most flag officers to-day make use of their staffs as a matter of course in the same way that general officers in the army have done for many years past. At the Admiralty (*q.v.*) there is a fully-equipped staff, the head of which is the First Sea Lord (Chief of the Naval Staff), whose business it is to study the problems of defence and to prepare in advance for any emergencies which may arise. This staff also forms the nucleus of the far larger organisation which the World War proved to be necessary on the outbreak of hostilities. Incidentally, too, it provides the necessary machinery for close co-operation with the staffs of the other two fighting Services. The three professional heads of those Services meet from time to time as a Chief of Staffs Committee, where matters are discussed and joint proposals formulated in preparation, if need be, for meetings of the Committee of Imperial Defence (*see* NAVAL STRATEGY AND TACTICS).

Apart from its other advantages, the staff system, as it works to-day at the Admiralty, provides a body of officers whose energies are not absorbed by questions of material and supplies, these being dealt with by other departments. Nevertheless, even here there is the necessary co-ordination to ensure that plans, preparations, construction and supplies should march hand in hand.

(E. A.)

United States.—An act of Congress of Feb. 14, 1903, created a General Staff Corps and provided for the appointment of a Chief of Staff of the U.S. Army. No similar corps or Naval Staff has ever been authorized for the U.S. Navy, but an act of Congress of March 3, 1915, provided for the appointment of a Chief of Naval Operations specifically charged, under the direction of the Secretary of the Navy, with the operations of the fleet and with the preparation and readiness of plans for its use in war. In a general way the Chief of Naval Operations holds a position in the naval establishment corresponding to that of the Chief of Staff of the Army, but there are many and important differences in the duties and responsibilities of these two officers. The Chief of Naval Operations is appointed by the President by and with the consent of the Senate for a term of four years. The position carries with it the rank of admiral and precedence over all other officers in the naval service.

The Chief of Naval Operations is charged under the Secretary of the Navy with the organization, operation and training of the fleet and its readiness for war. He co-ordinates matters relating to repairs, alterations, docking, manning and outfitting of ships, and determines their military characteristics. He prepares war plans, drill books, signal codes and naval regulations. He directs movements, manoeuvres, strategical and tactical matters, drills and exercises. He advises on the position, capacity and protection of navy yards, naval stations, fuel reserves, radio stations and other reserves and supplies. He handles naval matters touching on foreign relations and performs other duties as set forth by naval regulations, or as directed by the Secretary of the Navy.

In order to carry on the varied and detailed duties imposed on the Chief of Naval Operations his office is divided into a number of divisions or sections whose functions are indicated in a general way by their designations as follows. policy and liaison, war plans, naval intelligence, naval districts, fleet training, material, ships' movements, inspection, naval communications and secretarial. Each of these sections or divisions is headed by a flag officer or captain of the line of the Navy except the Secretarial Division which is in charge of the Chief Clerk of Naval Operations. A flag officer is detailed as Assistant Chief of Naval Operations. In addition to the immediate activities outlined above, the Chief of Naval Operations has general cognizance over the Naval War College at Newport, R I., and is a member of the Joint Army and Navy Board, the Advisory Council of the Secretary of the Navy, and senior member of the General Board

The Chief of Naval Operations is not the Chief of the General Staff in the sense that such an officer is found in the organization of certain other naval powers, although he performs many of the duties that would ordinarily fall to such an officer. For instance, the Chief of Naval Operations is not superior to the chiefs of bureaux and independent offices of the Navy Department, although he takes precedence over them by virtue of his rank He is not, in fact, a link in the chain of command between the Secretary of the Navy and the chiefs of the various bureaux of the Navy Department who have the right, and freely exercise it, to consult the Secretary directly on matters concerning their bureaux, as well as to receive instructions directly from him

When trying to compare the office of the Chief of Naval Operations with that of the U S War Department General Staff, it is to be remembered that the Chief of Naval Operations actually directs and controls the Navy and the larger part of his duties are administrative whereas the Chief of Staff of the Army acts largely in an advisory capacity

The General Staff Corps of the Army is a separate and distinct staff organization whose officers are detailed to duty therein for a term of four years General Staff officers may serve in the War Department General Staff or on the staff of commanders of troops. There is no similar corps in the Navy, the officers on duty in the Office of the Chief of Naval Operations and serving on the staffs of flag officers ashore and afloat being detailed to this duty in the same manner as to any other duty

The differences between the staff organizations of army commanders in the field and of naval commanders afloat are even more marked than in the departmental organizations Officers of naval staffs are usually selected by the flag officer whom they serve, any officer available and acceptable to the flag officer being eligible for such assignment The number composing a staff depends primarily on the nature of the command, varying from one or more officers to as many as twenty Quarters and office space required for staffs, being additional to that normally required for the ship's complement, are extremely limited. For this reason the size of a staff must be reduced to a minimum and, therefore, the assignment of duties to individual staff officers is governed to a very large degree by the personal qualifications of the various officers of the staff. This assignment of duties tends to obliterate clear-cut lines of demarcation between fixed divisions of staff cognizance and produces overlapping in the duties of individual officers. Close supervision and co-ordination of staff activities by the Chief of Staff and whole-hearted co-operation between staff officers is essential to the smooth and efficient performance of the work of a large staff. (C. F. H.)

STAFFA (Norse for staff, column, or pillar island), uninhabited island of the Inner Hebrides, Argyllshire, Scotland, 54 m. W. of Oban by steamer, about 7 m from the nearest point of Mull, and 6 m. N. by E. of Iona. It lies almost due north and south, is ¾ m. long by about ⅓ m wide, and its highest point is 135 ft. above sea-level. In the north-east it shelves to a shore, but otherwise the coast is rugged and much indented with numerous caves. During the tourist season it is visited regularly by steamer from Oban. In section the isle has first a basement of tufa, from which rise, secondly, colonnades of basalt in pillars forming the faces and walls of the principal caves, and these in turn are overlaid, thirdly, by a mass of amorphous basalt On the south-east coast is the Clam-shell or Scallop cave It is some 130 ft long, and on one side of it the ridges of basalt stand out like the ribs of a ship Near this cave is the rock of Buachaille ("The Herdsman," from a supposed likeness to a shepherd's cap), a pile of columns, fully seen only at low water On the south-west shore are the Boat cave and Mackinnon's or the Cormorants' cave Fingal's cave, the most famous, situated in the southern face of the isle, is 227 ft. long On its western side the pillars are 36 ft high. The cave is the haunt of seals and sea birds

STAFFORD (Family). This famous English house was founded in England by Robert, a younger brother of Ralf de Tosny (Toeni), of a noble Norman house, who was standard-bearer of the duchy Robert received at the Conquest a great fief extending into seven counties and became known as Robert de Stafford from his residence at Stafford castle With his son the male line became extinct, and his sister's husband, Hervey Bagot, one of his knightly tenants, succeeded to the fief in her right (1194), their descendant Edmund de Stafford (that surname having been assumed) was summoned as a baron in 1299 His son, Ralph, conducted the brilliant defence of Aiguillon against the host of France, fought at Crecy and in the siege of Calais Chosen a Knight of the Garter at the foundation of the order, he was created earl of Stafford in 1351

His son Hugh, who succeeded as 2nd earl in 1372, served in the French wars From 1376 he became prominent in politics, probably through his marriage to a daughter of the earl of Warwick, being one of the four lords on the committee in the Good Parliament, and also serving on the committee that controlled Richard II. (1378–80), whom he accompanied on his Scottish expedition in 1385 He died next year on pilgrimage at Rhodes His son, Thomas, the 3rd earl, married in 1392 the daughter and heiress of Thomas, duke of Buckingham (son of Edward III), who, on Thomas's death, married in 1398 his brother Edmund, the 5th earl. Their son, Humphrey (1402–1460), the first Stafford duke of Buckingham, was placed by his descent and his possessions in the front rank of the English nobility

Henry, the 2nd duke, was attainted in 1483, but on the triumph of Henry VII. in 1486 Edward, the 3rd duke (1478–1521), regained the title and estates, and recovered the ancestral office of lord high constable in 1509 He was accused of treason and, after a nominal trial by his peers, was beheaded on May 17, 1521, a subsequent act (1523) confirming his attainder

Henry (1501–1563), the son of the last duke, was granted by the Crown some of his father's manors for his support, and, espousing the Protestant cause (though married to a daughter of Margaret, countess of Salisbury and sister of Cardinal Pole), was restored in blood on Edward VI.'s accession and declared Lord Stafford, as a new creation, by act of parliament His second surviving son, Thomas, eventually assumed the royal arms, sailed from Dieppe with two ships in April 1557, landed at Scarborough, seized the castle, and proclaimed himself protector He was captured and executed for high treason His father's new barony, in 1637, passed to a cadet in humble circumstances, who was called on, as a pauper, to surrender it to the king, which he did (illegally, it is now held) in 1639 The king thereupon bestowed it on Mary Stafford (the heir general of the line) and her husband, William Howard, in whose descendants it is now vested Roger, who had surrendered the title, died in 1640, the last heir male, apparently, of the main line of this historic house

See Dugdale, *Baronage* (1675), vol i ; G. E C(okayne), *Complete Peerage;* Wrottesley, *History of the Family of Bagot* (1908) and *Crecy and Calais* (1898) The important Stafford mss in Lord Bagot's possession are calendared in the 4th Report on Historical mss , and the Salt Arch Soc s collections for the history of Staffordshire are valuable for early records. Harcourt's *His Grace the Steward and the Trial of Peers* (1907) should also be consulted The bishop of Exeter's Register was edited by Hingeston-Randolph in 1886 *Papers relating to the two Baronies of Stafford* (1807), and Campbell's *The Stafford Peerage* (1818) are useful for the pedigree, and there are collections for a history of the family in Add. mss. (Brit Mus)

STAFFORD, market town, county town, municipal borough, Stafford parliamentary division, Staffordshire, England, on the river Sow, a tributary of the Trent Pop (1921) 28,635 An important

junction on the L.M.S. railway and 133½ m. N.W. from London, it is also served by the L.N.E. and G.W. railways. The town, while largely modernized, contains a number of picturesque half-timbered houses. The church of St. Mary, once collegiate, with its canons mentioned in Domesday, shows transitional Norman, Early English and Decorated styles. The complete foundation is attributed to King John. It contains a memorial to the famous angler, Izaak Walton, born at Stafford (1593). The older church of St. Chad contains good Norman details, but is chiefly a reconstruction. The William Salt library, presented in 1872, has a large collection of books and mss. relating to the county.

Stafford (*Stadford, Staffort, Staforde*) is said to have originally been called Betheney from Berthelin, a hermit who lived here. In the Anglo-Saxon Chronicle it is stated that Aethelflead, lady of the Mercians, in 913 built a fort at Stafford, and a mint existed here in later Anglo-Saxon times. Stafford is a borough in Domesday Book, and the chief place in the county. The king received all dues, two-thirds as king, the other third as earl of Stafford. From the Domesday Survey it appears that the Conqueror built a castle at Stafford; this was destroyed in the wars of the 17th century. The existing ruin of Stafford Castle is that of an unfinished mansion (1810), which replaced the old stronghold. Beyond it is an early encampment, Bury Ring. A charter from John (1206) constituted Stafford a free borough.

STAFFORDSHIRE, a midland county of England, bounded by Derbyshire, Leicestershire, Warwickshire, Worcestershire, Shropshire and Cheshire. The area is 1,158·3 square miles. The county may be divided into three geographical divisions, north, middle and south Staffordshire, depending on the geological structure. The highest land is in the north. Here the southern ends of the Peak folds bring up Lower Carboniferous rocks, with limestones in the north-east and the Pendleside shales and Coal-Measures forming four basins in the north-west and centre. The district is drained by the headwaters of the Trent and its tributaries the Dove, Hamps, Manifold and Churnet and shows a diversity of scenery, the limestone hills being domed and treeless, whilst the Pendleside shales form heather-covered moors, and the grit bands have bold scarp faces. Axe Edge (1,756 ft.), and the Roaches are the highest hills, being formed by Millstone Grit. The four coal-basins are the Pottery, Cheadle, Shaffalong and Goldsitch Moss coalfields. The last two are small and contain only the lowest coal-measures and are no longer worked. The Pottery and the Cheadle basins are more important and contain valuable seams of coal. The Bunter sandstones of the Cheshire plain overlap the coal-measures in the west of the Pottery basin.

Middle Staffordshire is a broad undulating plain, occupied by various members of the Triassic series and drained by the Trent. The plain is divided into an eastern and a western portion by Cannock Chase, formerly a royal preserve, now an important coalfield concealed beneath a cover of glacial sands and gravel which rest upon Bunter sandstone. The high ground rises to about 500 feet. The "Black Country" occupies the greater part of South Staffordshire. Here again the country is low and undulating covered on its margins by the Trias whilst in the middle lies the South Staffordshire coalfield, in which there are several small inliers of Silurian rocks which stand up above the surrounding country to a height of 800 feet. Most of the county is drained by the river Trent, a few streams drain into the Dane which flows into the Mersey, whilst a small area in the west and south-west forms part of the Severn drainage system. The only considerable sheet of water is Aqualate Mere on the Shropshire boundary.

Staffordshire is an important coal-mining county. The Southern coalfield has an estimated reserve of 1,415 million tons and the northern coalfields 4,460 million tons. The latter contains the valuable black-band ironstones which are of commercial importance, and a smaller amount of iron is mined in the south where, however, there are important quarries for road metal.

History and Early Settlement.—Although remains of Palaeolithic man have been found in the Derbyshire caves over the border, no finds are known from Staffordshire itself. Neolithic implements, especially round barrows and Beaker pots of later date are found almost entirely and in fairly large numbers in the north-east section of the county. In early times this region must be considered as part of the Peak district of Derbyshire. In the remainder of the county there are isolated finds of Bronze, notably palstaves at Brewood, Biddulph, Bushbury and Stretton, a bronze sword at Alton Castle and a leaf-shaped spear-head at Yarlet. These isolated finds serve to indicate the beginnings of movement along the valley ways and the importance of the roads around the hills into Wales and the west. In Roman times Letocetum just south of Lichfield was the most important settlement.

In the 6th century a tribe of Angles settled about Tamworth, afterwards famous as a residence of the Mercian kings. Later the invaders advanced beyond Cannock Chase. The district was frequently overrun by the Danes, and it was after Edward the Elder had finally expelled the Northmen from Mercia that the land of the south Mercians was formed into a shire around the fortified burgh which he had made in 914 at Stafford. The county is first mentioned by name in the Anglo-Saxon Chronicle in 1016.

The resistance which Staffordshire opposed to the Conqueror was punished by ruthless harrying and confiscation, and the Domesday Survey supplies evidence of the depopulated and impoverished state of the county. The five hundreds of Staffordshire have existed since the Domesday Survey, and the boundaries have remained practically unchanged. The shire court for Staffordshire was held at Stafford, and the assizes at Wolverhampton, Stafford and Lichfield, until by act of parliament of 1558 the assizes and sessions were fixed at Stafford.

In the wars of the reign of Henry III. most of the great families of Staffordshire, including the Bassets and the Ferrers, supported Simon de Montfort, and in 1263 Prince Edward ravaged the lands of Earl Robert Ferrers and destroyed Tutbury Castle. During the Wars of the Roses, Eccleshall was for a time the headquarters of Queen Margaret, and in 1459 the Lancastrians were defeated at Blore Heath. In the Civil War of the 17th century Staffordshire supported the parliamentary cause, but Tamworth, Lichfield and Stafford were garrisoned for Charles, and Lichfield Cathedral withstood a siege in 1643.

Much of Staffordshire in Norman times was waste land, but the moorlands of the north afforded pasturage for sheep, and in the 14th century Wolverhampton was a staple town for wool. In the 13th century mines of coal and iron are mentioned at Walsall, and ironstone was procured at Sedgeley and Eccleshall. In the 17th century the north of the county yielded coal, lead, copper, marble and millstones, while the rich meadows maintained great dairies; the woodlands of the south supplied timber, salt, black marble and alabaster; the clothing trade flourished about Tamworth, Burton, and Newcastle-under-Lyme; and hemp and flax were grown in the county. The Staffordshire pottery industry is of early origin, but was improved in the 17th century. It has been greatly extended in modern times.

Architecture.—The most important churches are the beautiful cathedral of Lichfield, and the churches of Eccleshall, Leek, Penkridge, St. Mary's at Stafford, Tamworth, Tutbury and St. Peter's at Wolverhampton all of which are described elsewhere. Checkley, 4 m. south of Cheadle, shows good Norman and Early English details. Armitage south-east of Rugeley, has a church showing good Norman work. Brewood church, 4 m. south-west of Penkridge, is Early English. Audley church, north-west of Newcastle-under-Lyme, is a good example of Early Decorated work. The remains of the Cistercian abbey of Croxden, north-west of Uttoxeter, are fine Early English, and at Ranton, west of Stafford, the Perpendicular tower and other portions of an Augustinian foundation remain. Among mediaeval domestic remains are the castles of Stafford, Tamworth, Tutbury and Chartley. Beaudesert, south of Rugeley, is a fine Elizabethan mansion in a beautiful undulating demesne. In the south-west, near Stourbridge, are Enville, a Tudor mansion, and Stourton Castle.

Agriculture and Industries.—About three-quarters of the total area of the county is under cultivation, and of this three-quarters is in permanent pasture, cattle being largely kept, and especially cows for the supply of milk to the towns. Like most of the midland counties Staffordshire is well wooded.

The southern industrial district, the Black Country (*q.v.*), is

the main seat in England of iron and steel manufacture in all its branches. It covers an area, between Birmingham and Wolverhampton, resembling one great town, and includes such famous centres as Walsall, Wednesbury, Dudley (in Staffordshire) and West Bromwich. The northern industrial district forms the Potteries (*q.v.*); Cheadle east of the Potteries, is the centre of a smaller coalfield; Burton-upon-Trent is famous for its breweries Chemical works are found in the Black Country and at Tunstall, glassworks at Tutbury; there are also a considerable textile industry, as at Newcastle-under-Lyme, paper mills in that town and at Tamworth, manufactures of boots and shoes at Stafford and Stone, silk and artificial silk at Leek and other manufactures in the county include rubber goods, and motor cars.

Communications.—The main line of the L.M.S railway runs from south-east to north-west by Tamworth, Lichfield (Trent Valley), Rugeley and Stafford. This company and the Great Western serve the towns of the Black Country by many branches from Birmingham, and jointly work the Stafford-Shrewsbury line. The L M S. has branches from Trent Valley to Burton-upon-Trent, and from Rugeley through the Cannock Chase coalfields, from Stafford and from Burton-upon-Trent northward through the Potteries, with a line from Uttoxeter through Leek to Macclesfield The west and north line of the L M S. (Bristol-Derby) crosses the south-eastern part of the county from Birmingham by Tamworth and Burton with a branch to Wolverhampton. The L.N.E serves Uttoxeter, Burton and Stafford. A considerable amount of coal transport takes place along canals, the Black Country especially being served by numerous branches

Population and Administration.—The area of the ancient county is 749,602 acres with a population (1921) of 1,348,877. The area of the administrative county is 741,318 acres Staffordshire contains five hundreds, each having two divisions. It contains 6 county boroughs and 5 municipal boroughs The county boroughs are —Stoke-on-Trent, Wolverhampton, Walsall, Smethwick, Burton-on-Trent and West Bromwich; and the municipal boroughs are —Lichfield, Newcastle-under-Lyme, Stafford (county town) Tamworth and Wednesbury There are 26 urban districts which are.—Ablecote, Bilston, Brierley Hill, Coseley, Darlaston, Heath Town and Wednesfield Heath, Perry Bar, Quarry Bank, Rowley Regis, Sedgeley, Short Heath, Tettenhall, Tipton, Wednesfield, Willenhall, Audley, Biddulph, Kidsgrove, Smallthorne, Wolstanton, Brownhills, Cannock, Leek, Rugeley, Stone and Uttoxeter. Among other towns may be mentioned Abbots Bromley, Brewood, Cheadle, and Eccleshall There are two cities in the county, Stoke-on-Trent and Lichfield. The county is in the Oxford circuit, and assizes are held at Stafford. The county is mainly in the diocese of Lichfield, but has small parts in those of Worcester, Hereford, Southwell and Chester.

Staffordshire is divided into seven parliamentary divisions each returning one member, Burton, Cannock, Kingswinford, Leek, Lichfield, Stafford and Stone. The parliamentary boroughs of Stoke-on-Trent and Wolverhampton return one member for each of three divisions, and the boroughs of Newcastle-under-Lyme, Smethwick, Walsall, Wednesbury and West Bromwich each return one member. The county and parliamentary boroughs return in all 18 members.

STAGE, in architecture, an elevated floor, particularly the various storeys of a bell-tower, etc The term is also applied to the plain parts of buttresses between cap and cap where they set back, or where they are divided by horizontal strings and panelling. It is, too, the floor or platform on which plays are acted, whence the term has come to signify both the theatre (*q v*) and the drama (*q v*) *See* also STAGE DESIGN, below From its etymological meaning of a station comes the sense of a place for rest on a journey, the distance between such places, etc

STAGE DESIGN. Until about 1900 the pictures created on any stage, generally known as scenery, had no relation to the feeling for form, colour, composition or light which art from 1850 to 1900 had made a common possession. The picture of the world within the theatre was invariably dull, without illusion and rigidly painted,—painted, in fact, with the same merciless and metallic precision which led Manet to exclaim before one of Meissonier's paintings of charging cuirassiers, "Everything is of steel except their breast-plates." Trees stood invariably in regimental rows and their foliage hung in separate parallel layers above their trunks The walls of hovels or palaces reminded the most careless eye that they were merely painted canvas; the sky flapped, an obviously painted sheet The ugliness of the total result was all the more glaring because, in an age of realistic playwriting, actors were using every artifice they possessed to make an audience feel that they were Russian or Silesian peasants, Norwegian town councillors, or English clergymen and poets Every word in the theatre was trying to convince its hearers that what they saw was not actors, but human beings in a world as real as the one they had just left to enter the theatre; that people "were like that", that life had this significance and that meaning But everything on the stage reminded the audience that, after all, what they were seeing was a play in a thoroughly artificial place, the theatre, that had no relation to life. Even when a poet held the stage the result was equally ludicrous. It was difficult for the singers of Wagner to transport an audience to the beginning of the world, where the gods were deciding the destiny of men, when everything about them seemed an enlarged landscape done in chromolithograph Mary Garden wandered in a park that had neither magic nor mystery, in the supposed gloom of palace halls as bland as lithographs of English country houses, current in the '50s Any symbolism that might have lurked in Maeterlinck's fairy tale of the terror and foreboding of young love was dissipated; and Mélisande's cry "I am not happy" seemed less a comment on the state of her soul than on the preposterous stage settings that surrounded her.

The inadequacy of this type of scenic background, so prevalent at the turn of the century, did not lie alone in its artificiality nor in the fact that it was an obvious and flimsy convention Artificiality and the conventions of formally painted designs, as proved by the work of Inigo Jones, Bérain and the Bibienas, can breed beauty in the theatre just as easily as the same tradition in the 19th century bred ugliness. The reason for the change which makes painted scenery in one epoch enhance the meaning of the play and in another detract from it, is our changed attitude towards the theatre The creative dramatists of the past 40 or 50 years, whom for convenience sake we may call modern, such as Ibsen, Shaw, Hauptmann, Chekov and Strindberg, Synge and O'Neill, are modern in the sense that one and all they do not regard the theatre as a place of pure entertainment And they have succeeded so well that though we may still go to the theatre merely to be amused, we also go to watch a play with the same expectation with which we open a novel treating of modern life—in the hope of seeing more clearly into the springs of character, of getting a fresh sense of human destiny.

The Modern Scenic Movement.—The blatant dissonance between modern plays that were attempting to reconceive a world and scenic backgrounds that merely reflected the conventions of a purely theatrical theatre, was so preposterous that it could not endure. For that reason, directors of modern theatres in every country in Europe, beginning with Germany, and finally in the United States, enlisted painters or designers to make the world on the stage the world of the play. This is the genesis of the so-called modern scenic movement It arose, not because modern art already existed, but because it became essential to the theatre in order to quicken the reactions of the audience until the world the dramatist asked them to believe in had the plastic reality of a world before their eyes or the imaginative quality of a poet's dream. The source of modern scenery has not been dogma It did not arise because Gordon Craig prophesied that only screens could back a stage; modern scenery would have occurred whether or not Craig had ever existed or penned a line. He, however, was one of those who prophesied that a change must come and that stage settings must be designed to interpret the play they housed. Every manner and method of modern painting, has, with

the aid of some mechanical device, been put to work in the theatre: the plaster dome, in conjunction with the flexibility of incandescent lamps which made the painted sky seem a heaven and filled the stage with all the ambient light of day; the spot-light, manipulated to create the chiaroscuro of Daumier; light mixed with colour in the manner of Monet and Seurat making colour vibrate, and achieving the atmosphere of the impressionists, or enmeshed in gauze, giving the atmosphere of Whistler's nocturnes. Every technique of modern art has been exploited, whether of impressionism, post-impressionism, cubism or futurism. However, from the point of view of pictures constructed within the proscenium frame of the theatre, almost every method at one time or another, in the hands of a particular director and in conjunction with the methods of his actors, has succeeded in convincing an audience and projecting the interpretation of a dramatist's ideas.

The point needs stressing because the history of modern scenery is usually regarded from the point of view of a mere chronology of begetting, and is continued in the strain of prophecy. A designer reading any of the current histories of his art would feel that the entire problem before him was the choice of a style. And the value to him, as a craftsman, of almost all discussions of the subject, is hereby rendered nil. The theatre, it is supposed, is about to be re-created, purged of evil, saved and given its final form if he, the designer, only makes the right choice; screens, a stage without curtains, scenery made of nothing but curtains, a circus theatre where the actor can mingle with the audience, scenery that is only light, scenery that is merely symbolic colour, scenery that is wooden trestles, and so on, depending upon which method at the moment has had the latest critical success in Europe. It is essential for the scene designer to avoid this critical approach if he wishes to analyse the basis of his craft. For whatever his preferences may be as a painter, he will find that the moment he sets out to design stage settings his problem is everywhere the same. He will find the problem of relating a particular play to a particular audience, the problem, as conceived by the director, of how the meaning of that play can be put over the footlights, and dramatized for that audience. His methods will be deduced not from any abstract aesthetics of the theatre but from the exigencies of that particular situation. For not all his convictions as to why imitation and realism is a defunct method will prevent George Bernard Shaw from continuing to write plays so provocative that they must be acted in country-house gardens, Salvation Army barracks and physicians' consulting rooms, for which the designer will have to build the walls, find the furniture and even evoke the flowers. On the other hand, not all the dogmas in the world as to the value of realism will prevent Shaw, or any other playwright, from reconstructing Antony's adventure in Egypt or Adam's adventure in the Garden of Eden, for which there is an equally avid audience; and the designer will have to find a decorative equivalent for the sphinx, or some symbolic equivalent of the tree of knowledge. And whether theatre audiences are those of London, Prague, Berlin or Warsaw, the designer will find that they came to the theatre to share experiences that are not their own, so that in the course of a single season the designer may have to help in making plausible the romantic scruples of a Hungarian schoolboy or a Hungarian servant, the feudal scruples of Japanese noblemen, the political dogmas of Slavonic revolutionists, the moral codes of American revolutionists and Russian peasants.

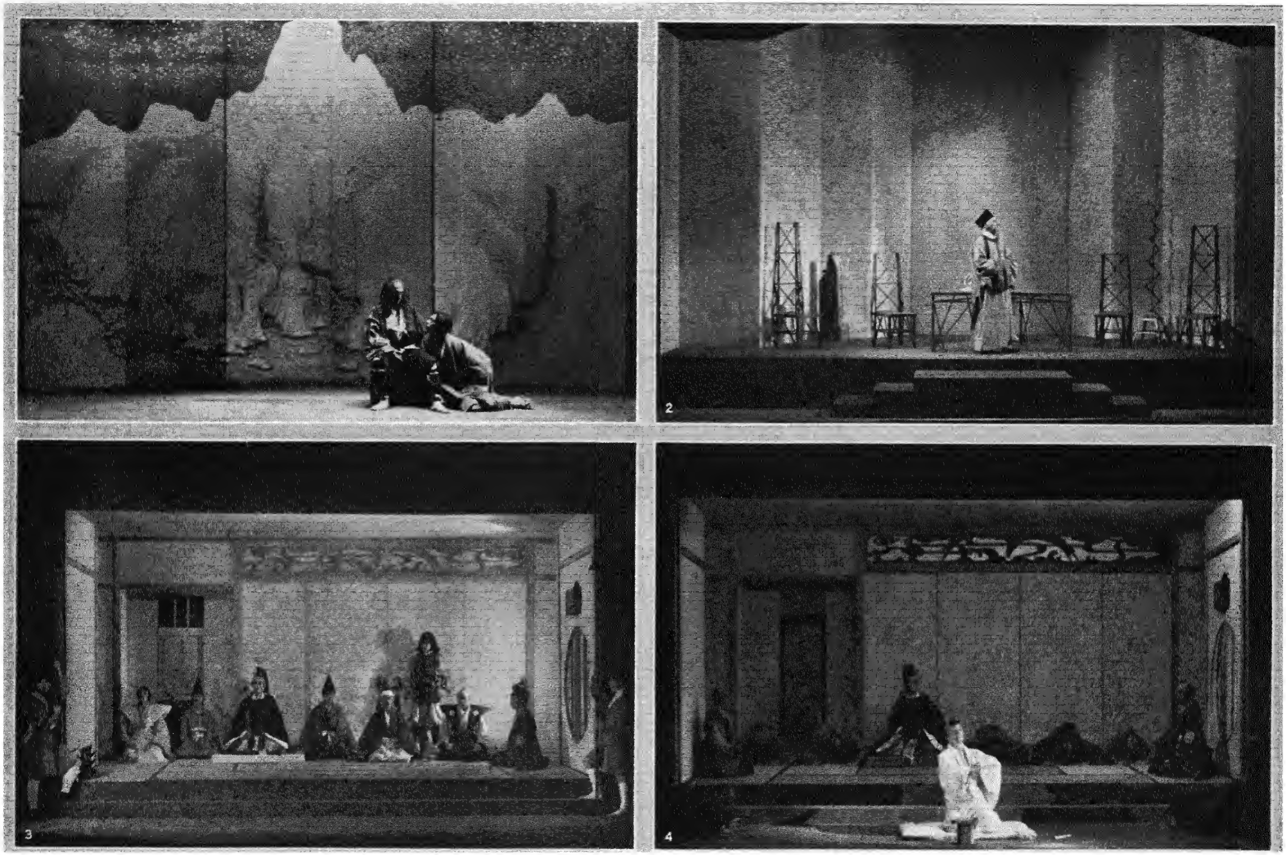
Staging of "The Faithful."—Some of the problems of scenic design as worked out by the present writer at the Guild theatre of New York, although not final in any sense as examples of theatre art, are typical of the problems which every stage designer must face in order to evolve design, whatever the pattern he may ultimately adopt. *The Faithful*, by John Masefield, tells the story of 47 Ronin, retainers and henchmen of a Japanese nobleman, tricked by a rival into committing an affront to the emperor's person for which the only expiation was suicide; of the voluntary exile of these Ronin as pariahs, and their final triumph over their dead master's enemy. It is a poet's celebration of the nobleness of loyalty. What is the producer's problem? Obviously something more than to demand poetic background for a poetic play, because the tale of the 47 Ronin, as much of a household story in Japan as Washington and the cherry-tree in America, is totally unfamiliar to Western audiences. He can count on no background in the audience's mind. But Japan is the background which he must create decisively five minutes after the curtain is up, for the reason is that the unforgivable act committed was nothing more than a mistake in ritual, a failure of ceremonial observance, not to the emperor himself, but vicariously to the emperor's person as personified by his envoy. The rigid code of Japanese feudalism is a tradition difficult for Westerners to conceive. The danger is that they will find it, if not preposterous, at least not plausible, so that they cannot identify themselves with the hero. The problem here is that to an audience not composed of orientals or members of Japanese societies, the normal reaction would be "Stab oneself because of a mistake in court etiquette? How preposterous! What a trivial people."

The playwright cannot solve this problem in the many ways that are offered to the novelist; he has no preliminary chapters or incidental comment to prepare the mind of his audience, as his story proceeds, to make them understand the rigid Samurai code of honour and accept the tragic alternatives imposed on its adherents. Aware of this problem, the designer finds, in making his first researches into the field of Japanese costume and architecture, that ritual ruled not only court etiquette but all Japanese life of the period, to the most trivial detail. Everything is prescribed and ordered; the degree to which the head is shaved, and the degree to which the hair is looped forward on the head; the precise way the obi or white silk belt is tied that holds the pleated skirt in place; the length of the sleeves, as well as the cut of the gown. Everything is ordered ceremonial, even the squares of the matting, the placing of the sword in its rack, the one picture niche where the solitary landscape scroll is shown and the way the single group of flowers is arranged under it. There are in the simplest acts, of receiving a friend and taking tea in his presence, countless opportunities of outraging him by breach of etiquette.

In a world of this sort, it begins to be comprehensible that a mistake in court etiquette could involve the death penalty. Hence every effort—and here the producer co-operates—is made to convey the ceremoniousness of the Japanese feudal world, in the gait of the actors, their gestures, their genuflections, the mode of entering or leaving a room. A Japanese is found to train them; he ties every obi, adjusts every costume, sets every hat and wig. The room which is the opening scene of the play is almost archaeological in its accuracy, and the line of every costume is established with realistic nicety and with an attention to correct cut and material that could hardly be outdone by the Moscow Art theatre. In short, realism as a method is employed in order to make a poetic theme plausible.

On the other hand, once the world of the Samurai is realized, and the tragedy is enacted, there is no further need of such realistic devices. The ragged Ronin wander in the snow, but the snow may be the snow gorges of Japan, painted upon a six-fold Japanese screen, without diminishing either the reality or the suffering of these outlaws. Here a deliberately decorative method seems the inevitable choice. Japanese landscape is known to Western audiences through the popularization of Japanese prints. A screen setting evokes this purely decorative pictorial tradition and suggests the countryside of Japan far more effectively than any attempt to reconstruct it realistically. Thus meticulous realism and deliberate decoration can be employed simultaneously in the same play, and for the same purpose. As pictures the snow scenes are far more effective (*see* Plate I.). But in the theatre the palace scene (*see* Plate I.) was far the more important of the two. For if that scene succeeded in conveying Japan effectively to the audience, the world of the Japanese could be taken for granted for the rest of the evening. A white sheet and the shadowgraph of a few pine boughs might have done just as well for the winter hills. This instance reveals how superficial it is to codify stage sets according to purely pictorial principles.

Staging of "Liliom."—Molnar's *Liliom* presents an analogous problem of transplantation, not from one century to an-



SETTINGS DESIGNED BY LEE SIMONSON FOR PRODUCTION BY THE THEATRE GUILD, NEW YORK; PHOTOGRAPHS, (1-4) BRUGIERE

THE USE OF SCREENS AND AN EXAMPLE OF DRAMATIC LIGHTING

1. Snow scene formed by a painted six-fold Japanese screen. In "The Faithful" by John Masefield
2. Office of the prime minister, A.D. 2170, a setting in which screens are used as a background. In "Back to Methusaleh" by Bernard Shaw
3. Reception of the Imperial Envoy in "The Faithful." The snow screen was placed directly in front of the opening, making an out-of-door scene without shifting the main set
4. Suicide of the hero in "The Faithful." The setting is the same as that in fig. 3, the change, suggestive of a more tragic mood, being effected by means of lighting

THE ABSTRACT SETTING

1. Scene from "Man and the Masses," an example of the formal stage in which mass movement of the actors creates the design
2. Revolution scene in "Man and the Masses," a complete change of mood and design by a change of mass action
3. The miracle in "Tidings Brought to Mary," a play in five acts by Paul Claudel presented throughout on the same platform with changes in lighting only
4. The farewell supper in "Tidings Brought to Mary"

other but from one country to another at the same period. The producer's problem in Liliom was, in essence, that his story deals with the creed of a gangster and a "tough" who is fundamentally romantic. Liliom falls genuinely in love with the servant, Julie, and evinces a belief in "the eternal feminine" worthy of a latter-day Faust. He is transported by the prospect of fatherhood. When he stabs himself rather than be captured by the police in an attempted hold-up that fails, his last cry is "Julie . . . my little girl . . . my little cricket." When, after facing the judgment of heaven and ten years' probation, he returns to earth as a beggar for an opportunity to win redemption, he steals a star to give to his daughter, and then in a moment of exasperation beats her, as he formerly beat her mother. The child cries "he hit me . . . but I didn't feel anything—as though someone had stroked my hand . . ." "Nothing has happened" her mother assures her, divining who the beggar is, "it is possible, my child, for someone to hit you—so that you don't feel any pain." Liliom is not forgiven in heaven; he is redeemed on earth by the persistence of human compassion. The beauty of the final scene made the play at the Guild theatre an allegory, the vindication of a romantic faith, and dictated the scenery The play was something more than the story of a foreign underworld; its realism was made an ironic cloak for poetic truth. Thus the amusement park where Liliom flourished as a bully was made as authentically Hungarian as possible, so that the audience might accept the reality of a romantic gangster and not reject him as a maudlin invention On the other hand, precisely because the play seemed important as an allegory because of its poetic truth, the tawdry squalor of Liliom's surroundings had to be invested with beauty, even the tumbledown shack in which he lived. And the railroad embankment, where he attempted his hold-up and met his death, was composed with some of the dignity and severity appropriate to tragedy.

Scene 2 represents the park where Liliom falls in love. The point is that, bully, seducer and braggart though he is, he does fall genuinely in love. He is transfigured and the moment becomes as beautiful for this Hungarian hooligan and a kitchen maid as it does for all lovers. Therefore, the park where they meet must be made beautiful The hour is dusk, when, as Whistler reminded us, "the evening mist clothes the riverside with poetry as a veil, and the tall chimneys become campaniles. and the warehouses are palaces in the night and the whole city hangs in the heavens"; the "exquisite hour" as Verlaine calls it. Therefore the problem for a designer was to clothe that park with poetry as with a veil; with tree silhouettes hung on transparent gauzes (*see* Plate III.); putting into those tree silhouettes all the grace and the loveliness appropriate to the trees of a pastoral bower destined to arch over young lovers. Had the scene been one of cynical seduction, this quality of tenderness and brooding would have been irrelevant.

Scene 6 represents heaven. Liliom sees heaven in terms of the police courts with which he is familiar He can conceive of no other bar of judgment; heaven is merely the last police court presided over by a police-court judge; the attendant angels are to his eyes only detectives and policemen. The stage directions emphasize the fact by stating that their costume is the usual police uniform. Nevertheless, Liliom has died; he is in heaven awaiting eternal judgment If the play is to be properly interpreted this seat of judgment cannot be the proverbial heaven with a celestial throne. On the other hand, if the allegory of the play is to be made plain it cannot be shown simply as a police court This dilemma was solved by making the scene as far as Liliom's eye ranged a drab room, with the ordinary judge's bench at one end; but the solid walls ended at the wainscoting and window frames. Beyond that was emptiness; the room sat without walls or roof under a blue sky as illimitable as stage light could make it. By this combination of realism and fantasy, the reality of heaven was established for the audience, and at the same time the fact was made clear that to Liliom its judgments were no different from what he had experienced on earth. These four scenes from two plays entirely different in type demonstrate how contradictions of realism and decoration in stage pictures are determined by problems of dramatic interpretation and not primarily by pictorial considerations. The picture is a result of a conviction as to what the meaning of a play is and how it can be reflected in pictorial form.

The Method of Abstraction.—Settings that eliminate the stage picture entirely are designed for the same reason and by the same process. *The Tidings Brought to Mary*, by Paul Claudel, was played on the same platform for its entire five acts, which according to the stage directions take place in a barn, a farm kitchen, an orchard and a road at the edge of a forest. Fedor Komissarjevski, the director, chose the unit platform because he felt that the play was mediaeval not only in its story but in its quality. It was a mystery, couched in the mystic faith of a truly mediaeval catholicism. A single square block served as a bench and, covered with a formal cloth, as a supper-table and an altar (*see* Plate IV.). The orchard became eight nuns clothed in Byzantine splendour, each holding a branch of silver flowers, who stood in a remote semi-circle. The sky behind them at this moment became green to suggest the foliage of out of doors. For the road-side scene at night, the same backdrop became the inky blue of a wintry night spangled with a few stars And a cold steel-blue light thrown over the platform gave the illusion of winter snow For the miracle the sky blazed forth gold, like the background of a 14th century mosaic, and aureoled the actors The same intention was carried through the costumes: many were mediaeval French, but others—those of the father and mother—were clad in the traditional robes of early religious paintings, so that the mother had a suggestion of the Mother of Christ, the father, of one of Christ's disciples, and in its formal grouping, the supper of farewell suggested an apostolic meal.

In *Man and the Masses*, by Ernst Toller, the formal platforms became almost invisible. The settings were made wholly by the massing and the movement of the actors The human beings on the stage provided all the scenery that was needed, for the play was conceived as an abstract allegory. One leader who tries to limit the workers to the bloodless methods of a general strike, is called simply The Woman. The agitator who incites them to revolution is called The Man. Though the workers are supposedly in their union hall, their angry indictments of capitalistic society are chanted in unison as a formal chorus How could this meeting be placed in a realistic setting of an actual union headquarters, without making such formal choruses seem ridiculous? The title literally translated is "mass-man" The force of Toller's conception is his vision of mass-man. The working-men are a single stubborn unit, welded together in resentment and anger, from which only voices of the young and the old emerge to cry, threaten and lament. If a group of 30 or 40 actors on the stage are to give this feeling of mass power, they cannot be scattered, they cannot move about much; they must be welded. Hence a stage setting was devised that was a literal cross-section of an amphitheatre; the players never moved from the spot where they were wedged; they rose with waving arms and clenched fists to face The Woman, who pleaded with them (*see* Plate IV.); they towered over her; she was below them, supplicating. When this compact mass of 30 actors stood they seemed to represent "the masses"; it seemed that they could sweep down on The Woman and overwhelm her Then The Man sprang out of their midst and slowly backed up step by step to the top of the amphitheatre. As his eloquence grew they swung slowly round, looking up towards him, turning their backs on The Woman as they ignored her pleas Finally, at the moment when they were won over to a doctrine of violence, they were a solid mass, crouching under him waiting to spring; as he cried "revolution" they took one step up, the only step they took in the entire act, and lunged together like a huge beast, echoing his cry "revolution." Each one had turned completely round during the scene without once moving from the spot on which he or she stood. They remained a mass, and by a single mass movement expressed their change of faith.

Varieties of Interpretation.—The designing of scenery is thus never a purely pictorial problem; it is part and parcel of the act of interpreting a play. Whether a designer chooses abstraction or realism, a picture-stage which imitates the world as we see it

in rooms with the fourth wall knocked out into which we peep, or a formal stage which symbolizes the world, is in itself a relative thing. The method of design chosen is only good even from a pictorial point of view provided it touches the imagination of an audience, and really convinces it of the truth and reality of the play. Setting the play is only part of the process of acting it so as to give it dramatic force; no method, however beautiful it is as a picture, is the right method if it fails to convince an audience; and there are as many types of audience as there are kinds of play. No play has only one meaning; it can mean all things to all men. The imagination of the director must decide and the pictorial imagination of the scene designer must second him. If you can make your audience accept Liliom's story as a modernistic fairy-tale, an allegory from the outset, Pitoev's method of presenting it in clear hard formal outline is the right one. If the play means more as a story in which the allegory is implicit, then the more realistic method of the Theatre Guild is better; similarly with *He Who Gets Slapped* (*see* Plate II.). To compare the two one would have to sit through the two productions as played by two different casts.

There is no one way of producing any play, even classic masterpieces. In fact every one, whether Euripides or Shakespeare, has to be constantly re-interpreted, in order to become relevant and remain living. If Shakespeare's characters seem important as figures rescued from an actual historic past then the elaborate and exact costuming of the Duke of Saxe-Meiningen or Henry Irving is not only necessary but effective. To one audience, which conceives them primarily as creatures of Shakespeare's time, the bare boards of the Elizabethan stage will make them live more completely. To another audience, particularly sensitive to Shakespeare's word-magic, formal scenery, even a single curtain, is enough. To a German audience, for whom much of the poetry is lost in translation, more pictorial backgrounds are necessary, into which that lost glamour must be projected. But to both German and American audiences for whom Shakespeare's protagonists are imaginative figures living in the world of the imagination, they become most real when part of an unreal world, a forest of dyed strips of tapestry or gauze (Barker's production of *A Midsummer Night's Dream* and Reinhardt's production of the same), or a blood red stairway (Jessner's production of *Richard III.*), or among golden screens (Craig's production of *Hamlet* with Stanislavski at the Moscow Art theatre). And if the tragedy of Hamlet begins to seem too remote and archaic to us, we can make him a human being, for certain audiences, by putting him in modern dress. The art of scene designing is a living art because it can find no final formula. It will live precisely as long as it can discover new meanings in every play of every epoch. Scenery is the background of a play, and as such is part of the continuous adventure of projecting the meaning of a play across the footlights, finding, firing, and then fusing the imagination of an audience. And that adventure will always be a different one in every country and every epoch.

Structural Innovations.—The technical and structural changes which determine the design of modern scenery are two: first, the modern theatre, in contrast to the 18th century theatre, has become an extremely shallow box; second, that black box can be completely flooded with electric light, modulated and controlled. The theatres of the late 17th and 18th century fixed the architectural type of our theatres, which with changes of ornament and the depth and arrangement of balconies is the type still prevalent to-day. But there is one vital difference: the proportion of the space occupied by the stage in relation to the space occupied by the audience in the auditorium. The 18th century stage averaged in depth 1 to 1½ times the depth of the auditorium pit, and was rarely less than 75 feet. To-day, the stage, except in opera houses and foreign State theatres, is rarely more than ⅓ the depth of the auditorium, and averages at the best 25 to 30 feet.

Moreover the 18th century stage was carefully calculated to enhance painting in perspective. The stage floor sloped up. The side flats receded until the rear of the stage was very near the true vanishing point, so that an alley of trees or an avenue of columns receded very much as they would in nature. But on the stage of to-day the spectators are looking into a space so shallow that any illusion of depth is difficult to attain. In an average production there is rarely more than 8 to 10 ft. from the garden wall to the distant mountains; often there can be only 4 or 5 ft. from a window to the sky.

The early technique of shifting scenery was done by having the side flats on grooved slots, set in pairs, tied to a rod which connected with a series of windlasses in the cellar. At a given moment one turn of these windlasses would shoot the rear flats out like a shutter, and withdraw the front flats out of sight, achieving a complete change of scene with great precision. A beamed gridiron under the ceiling, with another series of windlasses, hoisted and lowered the clouds and the platforms on which gods and goddesses descended. Owing to the shallow space of the modern theatre and the suppression of the apron in front of the curtain, the front rows of spectators can see clear to the roof and to the side walls. The modern stage settings therefore have had to become a three-sided box with a lid over the top, when interiors are called for; for exteriors a curved sky, either of canvas or of plaster is used, instead of a sky in flounces as seen in the 18th century theatres. There is so little room on the stage for stacking scenery that most of it has to be broken apart, or unlashed, for each change of scene, and hoisted into the air where it hangs until it is needed again, and as certain sets may be 24 and sometimes 30 ft. high they have to be hoisted high enough to be out of sight when not in use. Hence the gridiron from which scenery is hung—handling is facilitated by having the lines that haul it attached to counterweights grouped at one side of the stage,—is the most important part of standard stage equipment. The opening which the audience sees, the proscenium frame, is in reality a mouse-trap shutter at the bottom of a tall shaft. The average proscenium opening is 24 to 30 feet. The curtain in actual use is rarely drawn higher than 20 ft. for exteriors, and 12 to 14 ft. for interiors; the remaining space is occupied by flounces and draperies. And the gridiron must be a minimum of 65 ft. in height; for hauling scenery out of sight, 80 to 85 ft. is better. At the Century theatre, New York, it is about 100 ft. above the stage floor.

In any case the space behind the stage opening is mainly storage space for hanging scenery in mid-air. The place occupied by the largest scene is approximately one-seventh of the total stage space, and the proportion will not vary greatly in American theatres or most commercial theatres of Europe.

The system outlined above is not by any means the best either mechanically or aesthetically. It is, in method, as archaic as hoisting sails; indeed the workmen on the stage who shift scenery are known as the crew to this day. The revolving stage introduced by Lautenschläger from Japan was used extensively, and did away with the necessity of a gridiron almost entirely. At Dresden, Linnebach at the State theatre and Hasait at the Opera, constructed elevator stages worked by hydraulic power, so that heaviest sets could be set in the cellar, hoisted to stage level and slid into place with extraordinary speed. The cellar being two or three storeys deep, the settings for two or three entire productions could be kept intact indefinitely.

These mechanical marvels have never developed because the economic trend of the time is against them. Land has become too expensive to allow the amount of space and excavation required; rising costs everywhere in Europe make the duplication of any such installation prohibitive. In the United States where a single elevator platform 12 by 30 costs approximately $25,000 to install, an entire stage so equipped would represent a capital investment that not even the wealthiest theatrical producer could carry. Thus theatres tend to become smaller and shallower and the theatre everywhere approximates to American conditions where everything has to be crowded into a standard building site of 100 ft. square.

Important architectural experiments have been made which aim at changing the conventional "peep-show theatre," as its critics have called it, where we look into a stage picture through a more or less gilded frame. Theatres have been projected with the stage as a formal platform, where the actor emphasized in space, picked

4 WALTER HAMPDEN'S PRODUCTION OF CYRANO DE BERGERAC—CLAUDE BRAGDON Archt

THE USE OF SCENERY "WAGONS" IN REALISTIC SETTINGS

The scenery wagons formed the keystone of this production of Rostand's "Cyrano de Bergerac," reputed to be the most difficult play to set according to the author's direction. Each wagon is rectangular, about 8 ft. by 12, with one floor or platform 18 in. above the stage and a second 7 ft. higher. They are mounted on ball-bearing wheels and all four sides covered by 24 ft. "flats" containing doors, windows, arches, balconies, and so forth. By rolling these wagons into different positions and exposing different faces to the audience at different times; by combining them in one scene and separating them in another, and by supplementing them with sections of scenery of the ordinary sort it is possible to meet all the acting requirements and at the same time differentiate the scenes sufficiently to deceive all but the most expert and analytical eye. By this device the high and heavy scenery for all five acts is both set and stored before the rise of the opening curtain and the interiors of the wagons can be utilized for the storage of stage "properties" of which there are more than 200 in the cook-shop scene alone (fig. 2). This principle of the double and triple use of material extends to the minor items of the scene as well. The front of the inner theatre stage in the first act (fig. 1) becomes the counter in the cook-shop scene next following (fig. 2). The stairway which appears in the first, second and third acts is the same stairway, masked differently in each case. The ramparts in the fourth act (fig. 4) become the box hedges in the fifth (not shown in drawings) by the removal of the dyed burlap which has been thrown over them to give them the appearance of earthworks

out by light, can mingle freely with the audience and is partially surrounded by them, a sort of electric contact being the goal sought. The most notable theatres of this sort have been the projects of the American Geddes, the Dutchman Vanderwelde and the Austrian Stranad. Jouvet's platform stage designed for Copeau existed in Paris for a number of years; a circus theatre by Poelzig, "the theatre of the 10,000," was actually built in Berlin, but like Copeau's theatre it was abandoned. Quite apart from economic problems, what thwarts the development of these playhouses is the fact that modern playwrights will not write enough plays that can be given in any such manner. O'Neill and Shaw, Toller, or Werfel, revert to realism quite as often as they depart from it and write plays which require the three-sided box room or the illusion of distance in an actual world which can only be achieved, in the theatre, by looking through a frame. Until modern playwriting achieves some unity of tradition, these formal stages must remain isolated experiments or dreams on paper.

Lighting.—The most important effect that the shallow-box stage has had on designing is the fact that perspective planning and painting become preposterous; anything that leads the eye from the front of the stage directly across it to the back wall, makes the eye realize that the picture is only 20 ft. deep. Hence the kind of composition modern scene design employs is not the Renaissance composition of distance into which the eye is led by receding parallel perspective, but distance suggested in the Japanese manner by planes cutting one another like the distant peak of Fujiyama appearing directly over the brink of a hill. The eye, leaping from one to the other, imagines the distance and gets the suggestion of space. Thus a space in modern settings is suggested rather than revealed: the base of one column will suggest an entire temple, one pillar in a gloom pierced by a stained glass window will convey an entire cathedral, and because there is no intermediate form between the pillar and the window, the blackness will seem as deep as the nave of a church. Even the window may not be shown but a shaft of light may be thrown from a point out of the spectator's range of vision in order to increase the scale by the same process of suggestion.

Light is the scene-painter of the modern theatre; light, not paint, draws the scene, and by varying planes of intensity, models it, and makes the corner of a building solid, a hill remote, a sky infinite though it be only two arms' length from the garden wall. If a stage 25 or 30 ft. deep is flooded with even radiance, nothing will persuade the eye that it is anything but a shallow box, however suggestive the arrangement of the setting itself may be. Settings are constructed now as in the Renaissance period, of canvases stretched on wooden frames and hinged or lashed together, but the paint on them is a mere preparation for the light to be thrown on. No setting can be designed until one is certain how one is going to light it; the colour painted is conceived as an undertone of what it will seem when lighted on the stage.

The railway viaduct in *Liliom,* for example, if it is to seem massive and menacing must have the light thrown across it, not at it, otherwise it will become flimsy canvas. Thrown from right to left the single pier casts a sharp shadow which gives a sense of solid masonry. The whole forepart of this scene must have a different quality and intensity of light from the distant silhouette of factory chimneys. With the right balance of light they will recede and seem distant even though they are actually only 8 ft. behind the arch culvert. And both foreground and background must be properly related to the sky if they are not both to fall into it.

So much for the scene; but there are the actors. They must be modelled and emphasized in the areas in which they move; sharply picked out at certain moments, where the action calls for it, at others almost blotted into half shadow, for this scene is one of ambush, of two thieves waiting to rob a cashier, and a rim of shadow into which they can retreat is part of the process of creating the atmosphere of terror and suspense when the crisis comes. Every scene has pools of light waiting for the actors, light which we do not see or know is there until the actor walks into it at a given moment.

Emotionally we react to light far more quickly than to any other medium in the theatre. We react to it even more quickly than to the actor's voice. In fact it sets the key of our emotions, and determines what effect the actor's voice will have on us. Lights not only paint and model the setting, emphasize its planes, and define its form; light also sustains the mood of a scene, and dramatizes its meaning. Crude or blatant lighting can war against the emotions an actor is trying to convey, and often destroy them entirely, all the more so because the lighting of any scene often does not remain static, but is dimmed or heightened, pulses and fluctuates with the action, like an orchestral score.

Change of light alone created every difference essential to the five acts of the *Tidings Brought to Mary.* The park scene of *Liliom* (Plate II.) consisted of two gauzes on which the silhouettes of trees were pasted. The entire mood of poetic dusk was created by a balance of lights. In *Man and the Masses,* the contrast between the mystic dream scenes (not shown) and the sculpturesque force of the mob scenes is entirely a matter of lighting. In the course of the play there were several hundred subtle shifts of lighting timed to coincide with the action of the play. The tree of knowledge in *Back to Methuselah* was entirely made with light, projected from the rear. The sphinx in *Peer Gynt* became a towering form by the same process. The sacred tree on the rim of the Persian desert in *Marco Millions* was merely a silhouette on a semi-transparent back-drop. But it towered in mysterious majesty because of the way light was thrown upon it, from both front and rear.

The technical basis of this important phase of modern theatre art is the spot-light—in contrast to the flood light—which can be controlled and focussed accurately upon one particular spot. To be effective these spot-lights must be separately controlled so that each can be set at any point of intensity from full to dim and fluctuated back and forth if need be during the progress of the play. Hence the rheostats, or dimmer board, that controls these lights, is to the designer's conception what the central nervous system is to the ideas in the brain. Increased subtlety both in design and control of electric light, and particularly the colour of light, is the key to theatrical design of the future. That must wait not only on the playwright and stage designer, but on the lighting engineer, who, more than anyone, holds the key to the modern theatre's destiny. STAGE EQUIPMENT

The mechanical equipment of present day stages exists for two purposes. (1) to change settings; (2) to light the stage. They are best considered separately.

Scenery Shifting.—The necessity of shifting scenery is supposed to be one of the characteristics of modern stagecraft, and the introduction of the first effective device to shift settings in the course of a play is assumed to be the turning point which determined the structure typical of playhouses to-day. The unity of place in the Greek theatre is usually pointed out in contrast and the assumption is common that imaginative Greek audiences, like those of the mediaeval market places and the Elizabethan inn yards, did not need the realistic simulation of changes of locale. Nevertheless, this orthodox doctrine is only relatively true. No

theatre of the Western world has ever been satisfied with completely immovable scenery. The attempt to vary and change the backgrounds of a play has existed from the beginning of drama in Europe.

Even the Greeks needed the literal descent of their gods from the machine—an obvious derrick that hoisted them over the permanent background of a palace or temple wall. And both Haigh and Flickinger agree that Greek dramatists felt the necessity of showing scenes inside the permanent and immovable background of their tragedies and comedies alike, and so put on a tableaux stage the murders which by literary convention had to take place off stage and could be described only by a messenger or a chorus. "This was a small wooden platform (eccyclema) rolling upon wheels which was kept inside stage buildings. When it was required one of the doors in the background was thrown open and it was pushed forward on the stage. . . . On it were seen the corpses of the murdered persons, the murderers standing over them with weapons in their hands. . . ." This device was also occasionally used in comedy. Flickinger cites the fact that traces of the tracks for the wheels of this scene wagon are said to have been found in the ruins of one of the Greek theatres in Asia Minor.

Although the mediaeval market-place theatre did not shift its scenery as a whole, it built the various scenes of its morality and miracle plays side by side. The actors shifted to the sets and walked from heaven to purgatory and to the hell-mouth, as the action of the play demanded. (*See* the well-known print of "The Valenciennes Passion Play" reproduced in almost any handbook on the mediaeval stage.) Certain of the prompt books of other market place festivals have been discovered which call for a succession of realistic effects, such as the water that was piped to the roofs of houses in the market place and then, at a given signal, released as the deluge; the machinery that literally hoisted Jesus up on high, or made the angels tremble and totter before their fall. It is doubtful whether the discovery of shifting scenery, usually ascribed by the authorities to designs by Inigo Jones and Webb in England, was not anticipated in Italy by the contemporaries of Serlio and Sabbatini. In any case Vasari contains references to Italian court masques where the heavens opened, gods appeared in chariots and descended, while mounds, bearing cherubs and flowering bushes and caverns breathing smoke, appeared through the stage floor, thus implying a use of machinery that would have taxed the resources of the Drury Lane Theatre of yesterday.

The effort to change the stage-picture is incessant. For some inexplicable reason it never occurred to any of these earlier experimenters to lower a curtain, hide the stage and do this shifting of scenery out of sight. Jonson describes a device used by Inigo Jones in staging *Tethy's Festival:* "Three circles of lights and glasses" moved circularly so distracted the spectators that they "scarcely discerned" that the scenery had changed from a seaport to a cavern. Sabbatini's handbook lists the various methods of distracting an audience's attention for just this purpose: someone in the back of the hall may pretend to start a brawl, a sudden fanfare of trumpets or the roll of drums may be sounded.

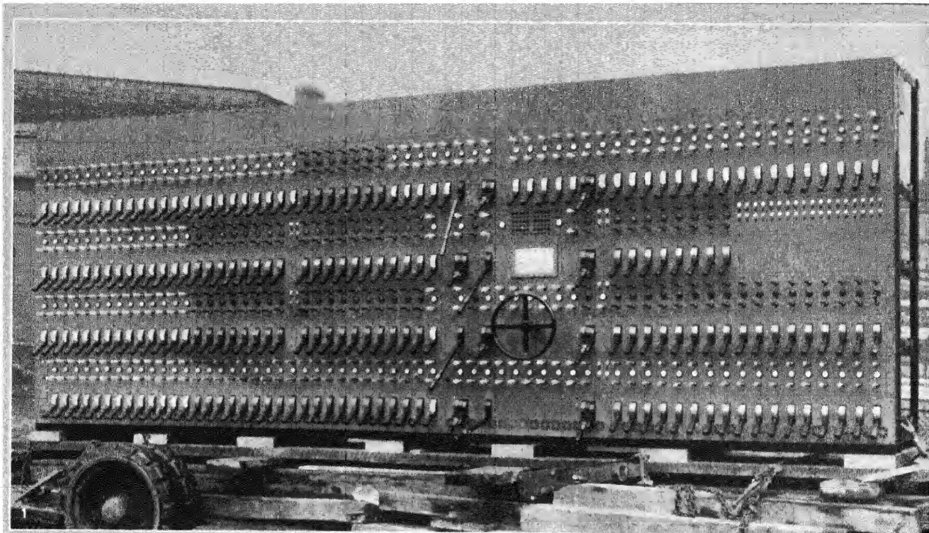
It has, however, become modern practice to lower the curtain and change (shift) settings out of sight of the audience, although this is occasionally also done with all lights out and curtain up on a dark stage. This mechanistic age has added very little that is modern to the devices of Renaissance and antiquity, except—and this only occasionally—to work them by electric or hydraulic power. The modern mechanisms which were generally part of the technical equipment only of German municipal and State theatres built between 1875 and 1900 are three:

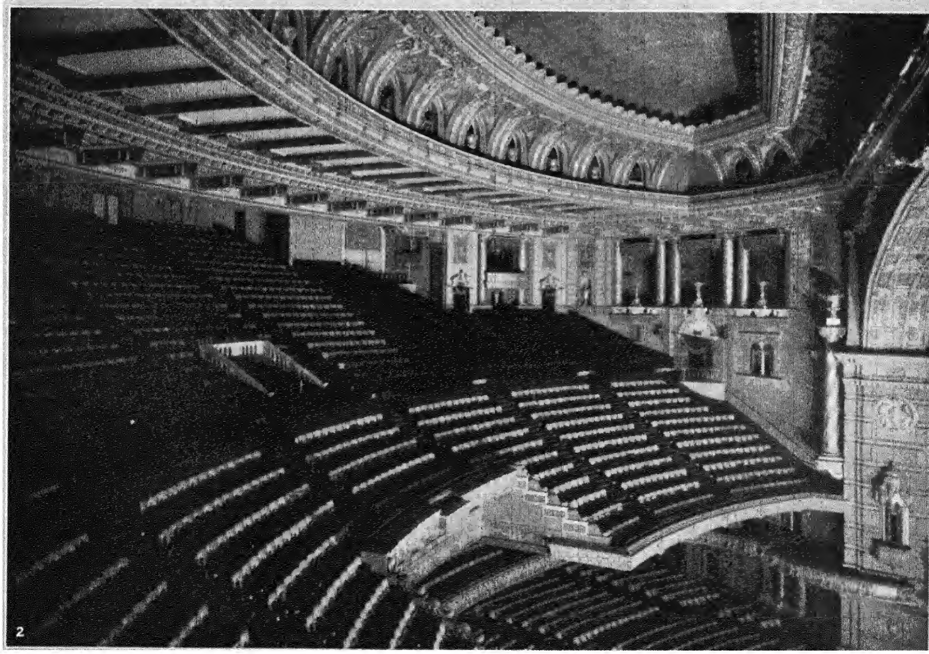
The Sliding Stage, in its essentials, the eccyclema of the Greeks, is built to run on tracks and is generally driven by electric power. Groups of two or three sliding stages are usually employed. Each sliding stage is as wide as the stage opening (called the proscenium opening or proscenium arch). While scene 1 is playing scene 2 is being "set" (set up) or is already in place. The curtain is lowered for an instant and scene 2 is pushed into space. The wagon stage, holding scene 1, is then "off stage" (out of sight) and can be rebuilt with scene 3 and the process reversed. Or if the scenes are not long enough to allow this, three sliding stages can be used and scene 3 be ready off stage with scene 1 drawn to the back (up stage). By the time scene 3 is over, there is invariably time for scene 1 to be "struck" (taken down) and replaced by scene 4, and the process continues indefinitely. The advantage of this system is that the time between shifts and scenes is reduced to a minimum; the disadvantage is that it requires a stage of such tremendous size that the ground rent of most cities precludes its use, unless the theatre is owned or subsidized by the municipality. For this reason this system of scene-shifting, notwithstanding its numerous advantages, has not become widespread.

The Revolving Stage, which was traditional on the Japanese popular stage, was seen there by the German technician, Lautenschläger, copied literally and imported into Germany. It is a turntable set level with the stage floor, and propelled by a windlass from below. The settings are arranged on it in rotation like the segments of a pie, all set before the play begins, and can be shifted in the twinkling of an eye. The advantages are obvious: speed of shifts and the fact that heavy and high constructions, such as rocks, walls, etc., can be used, which would be only slowly and laboriously moved in any other way. The disadvantages, less obvious, are: (1) In order to get a maximum number of scenes on to the circle of the turntable, they have to be triangular in shape—often a decided pictorial limitation. (2) Each sector must be so completely bounded as to hide the others, an open stage under a full sky, often artistically desirable, being impractical. (3) A deep stage for mob scenes, etc., often cannot be arranged for the same reason. (4) For any great number of scenes, as in a Shakespearian performance, even the largest revolving stage is inadequate. This can be obviated by ingenious dove-tailing for which Max Reinhardt and his designer Stern were particularly noted, and also by the practice, common in Germany, of beginning theatrical performances at 7.00 or 7.30 and having a half-hour intermission for refreshment in the course of the evening, during which an entirely new sequence of scenes can be set up for the rest of the evening. For this reason the revolving stage is not common outside of Germany. Moreover, for certain kinds of scene-shifts, as in Ibsen's *Little Eyolf,* where a three-sided interior must alternate with an exterior, an unobstructed view over the fjords, it is of no use whatsoever. The revolving stage cannot therefore be exclusively relied upon. And for that reason alone the expense of installing it usually bars it from being built as part of a theatre's equipment.

The Sinking Stage, of which the most notable types are those in Germany, built by Hasait and Linnebach for the Dresden opera-house and State theatre respectively. The stage floor from front to back is divided into three large platforms which are supported by elevator plungers. Each section can be raised independently to turn the stage into a series of grandiose terraces or lowered separately to the cellar and a new scene set and brought into place. In conjunction with sliding stages, as Linnebach uses it, there is no problem of scene-shifting that cannot be easily and successfully solved. The sinking stage allows for more freedom of design than the segmental system of the revolving stage, and the interior and exterior scenes can succeed each other with ease. It was devised to offset the limitations of the revolving stage which had become apparent by 1890. Unfortunately, it is extremely costly to instal. The machinery required to move these platforms, heavily-weighted with settings at sufficient speed to make scene-shifts quickly, is an elaborate piece of mechanical engineering, and the necessity for excavating a deep cellar underneath the stage adds greatly to the initial cost of constructing a theatre. For these reasons, except in playhouses whose repertory involves a daily change of classics or opera on a lavish scale, the capital investment is usually prohibitive. In consequence, elevator stages are not common even in Germany.

Machinery.—In this age of mechanical marvels the machinery commonly used for shifting settings is, except in details, not very different from that used in the French theatres of the 18th century. It is clumsy, involves a great deal of manual labour which yearly grows more expensive; it is slow in operation, except after





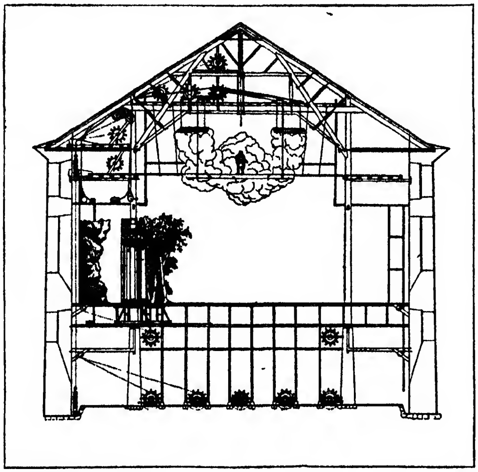
BY COURTESY OF S. L. ROTHAFEL, DIRECTOR OF THE ROXY THEATRE, NEW YORK

A LIGHTING SWITCHBOARD AND THEATRE AUDITORIUM

1. Huge switchboard of the type necessary in large, modern theatres. Each switch plays an important part in the lighting effects achieved
2. Roxy theatre auditorium. Spotlights, placed in the niches of the ceiling dome, may be regulated in fixed positions or used to follow moving figures on the stage. The dome lights are used to illuminate the orchestra during an overture, and are flexible enough for almost any type of lighting effect. Additional light units from the projection booth at the base of the balcony may be used for the same purpose

extended rehearsal (again adding an increasing labour expense to the cost of every production). Thus, although shifting settings is the typical demand of modern play, a play requiring more than two scene-shifts (which can be done slowly in the usual intermissions) remains the director's and scenic designer's greatest problem.

The typical equipment of to-day involves a rudimentary system for "striking" a set by hoisting it out of sight. It is controlled by



BY COURTESY OF SHELDON CHENEY

DIAGRAM SHOWING POSSIBLE EFFECTS MADE THROUGH STAGE MACHINERY

ropes or cables (lines), which are run to a slotted frame (gridiron) under the stage roof and then over pulleys to the pin-rail, where they are tied until the moment to "fly" them occurs. (*See* figure) This gridiron, usually of iron and formerly of wood, is about 60 to 80 ft. above the stage floor. The pin-rail, formerly in a gallery about 20 to 24 ft. above the stage floor is now usually on the stage floor itself as each piece of scenery is properly counterweighted so that it can be raised and lowered with ease without being hauled up as dead weight. There are three lines to each large piece of scenery, called the long, middle and short line respectively, according to the position of the pin-rail Any particular piece of scenery can be brought level to the stage floor or "trimmed" (tilted) by pulling more on the long or the short line or vice versa. However, these lines are only practical for pieces of scenery that can be set parallel to the front of the stage. Others can be set obliquely, but obviously they cut off the use of the number of sets of lines that intervene. (There are usually 50 to 70 such sets on the average gridiron.) Such slanting walls, palace fronts and exteriors, where the lines would be visible against the sky, must be handled by lowering them to the floor, snapping off the lines for the set and reversing the process for the strike For that reason shorter pieces, such as sides of rooms which set up and down the stage (perpendicular to the audience), garden walls, etc., are usually "stacked" (pushed off the stage) and carried on by hand. Those of the stage hands who "strike" and "set" are the carpenters. But the furniture, and all the other things, such as books, inkwells, papers, jugs, etc., which the actors use and handle during a scene, are brought by others called property-men. Ten to fifteen stage-hands are usually required to make a comparatively simple scene-shift. A series of quick shifts may require as many as 20.

A single setting though seen as a whole is, therefore, made to set and strike in a number of pieces, and then lashed together. But even these units are bolted together from smaller ones in order to get the set into the theatre and for ease in transporting it from town to town when on tour. The height of the average freight-car door in the United States, 5 ft. 9 in. determines the basic unit of scenery there. These "flats" or units, are still constructed as they were in Serlio's day in Italy in the 17th century; they are built on wooden frames (battens) and covered with canvas which is painted to simulate the texture of an exterior or interior wall Ornament such as door frame mouldings, window frames, etc., is applied and screwed to supporting battens behind. The element of weight due to the primitive and clumsy mechanics of current stage equipment, is an important factor in the designing of scenery. Every set must be designed not only for the play, but with an eye as well on the problem of striking and setting it Many intrinsically excellent ideas are therefore often discarded at the outset.

As an alternative the unit setting is often used This consists of a structural frame which remains standing throughout the performance. Inserts within it, small in size and easier to handle, are changed, thus giving the illusion of a change of locale. Such schemes stimulate the imagination of both the designer and producer, and are often as welcome to audiences as the easier reliance on literal realism.

This kind of simplification has often been carried further, as in Jessner's production of *Othello,* in Berlin, when a single pillar suggested the senate chamber, a bed on a platform, Desdemona's bedroom Nevertheless, such important playwrights as Shaw and O'Neill continue to write plays which require realistic settings And the inability of playwrights in general to confine themselves to any one tradition makes a steady use of any method of stylization impossible. Theatrical productions have become unceasingly a matter of competitive private enterprises for which costly mechanical installation is too great an investment risk Modern theatres are, therefore, still built, with rare exceptions, to house the equipment for scene-shifting described, which remains mechanically clumsy, crude, and wasteful of both time and labour.

ELECTRICAL EQUIPMENT

The incandescent electric lamp is the modern invention which has radically changed stage equipment Electricity is the one element of production which makes the modern stage different from any that preceded it. (For its place as an aesthetic factor in modern stage design *see* p. 285) The drastic changes in stage lighting (*v inf.*) made possible by electric light result from the fact that the current can be run over coils of resistance wire (dimmers) and the intensity of light subtly changed from one moment to another, to fit the changing mood or accompany reaction of a play Adolphe Appia was the first modern experimenter to indicate the dramatic importance of this method of lighting plays and the technique of stage-lighting is still very largely a development of his ideas outlined in *Die Musik und die Inscenierung.*

The first electrical equipment consisted of rows of small-powered incandescent lamps in narrow metal troughs (light borders) and hung in series of two or more rows parallel to the footlights which were relied upon to illuminate the actors' faces. These, with the other borders, were usually arranged in circuits of yellow (amber), white and blue—the lamps being dipped in a transparent dye—and each circuit dimmed or cut off to change the colour of any scene. The various drawbacks of this system were that the footlights, if sufficient to light the actors, flooded the settings with needless brilliance, casting shadows behind them The whole stage being flatly and evenly lighted, contrast and emphasis became impossible This type of light is very fittingly known as flood-lighting

The development of incandescent spot-lamps has greatly improved lighting. These consist of high-powered bulbs of 500, 1,000 and 1,500 watts in a metal hood which can be tilted to any angle, the light projected through a lens focused upon any given stage area. (A smaller, 250 watt type is known as a baby-spot.) The area of light can be spread or be narrowed down to the size of a face Spot-lamps were at first mostly used on a light bridge hung just inside the proscenium frame, where the electricians (operators) could walk to and fro and re-angle them as needed. Owing to the steady rise in the cost of labour it is a common practice to use more lamps previously set and angled for successive scenes. Some

are hung from a bridge or iron pipe overhead. But, as these tend to cast heavy shadows in the sockets of the actors' eyes, groups of 10 to 20 are mounted in a standing iron pipe (light tormentor) on each side of the stage (*see* diagram). Footlights are kept low and reinforced by additional spot-lights from the front of the first balcony or the ceiling of the theatre if space has been provided for them. In a recent production of *Faust* (at the Theatre Guild, N.Y., 1928) 80 spot-lights were used for its 17 scenes on the fore-stage alone.

The effectiveness of spot-lighting depends entirely on the flexibility of lighting control; *i.e.*, the dimmer. The only satisfactory system is to have each spot-light controlled by a separate dimmer so that every lamp can be brought independently to the degree of intensity required. But for complete changes of light, groups of lamps must be dimmed together. Hence the nerve centre of stage lighting is the dimmer-board, where the switches and dimmers are grouped; it may be compared to the sensory and motor nerve system of the body. The most important and difficult piece of mechanical construction in the modern stage equipment is this switch-board and dimmer-board and the coupling of both so as to obtain the greatest ease in controlling the lights in any desired order or grouping.

The American type of dimmer is not the most effective. In this the resistance, divided into 100 steps (called a dimmer-plate), is wound in direct connection with the handle that controls it, and then banked in rows behind the face of the board. They are heavy and cumbrous, and tend to overheat rapidly. The Theatre Guild switch-board of 102 dimmer-plates is 11 ft. long and 6 ft. high. Coupling or interlocking handles to bring down groups of lamps in unison involves much friction and is cumbersome to operate even in its most compact form. The German system of control perfected by Schwabe and the Allgemeine Elektrizitäts-Gesellschaft, is mechanically a great improvement. The resistance coils are stacked underneath the stage floor (or above it) in a fireproof chamber. A carbon-brush contact is connected by a fine cable brought to the stage over pulleys and wound on a counterweighted circular drum which serves as an indicator. As this indicator handle is shifted the contact brush in the cellar slides up and down. The great advantage of this system is that the indicator coils are small, being only cable controls, light in weight, and easy to move; the circular indicator is one-third the size of a standard American dimmer-plate, so that a bank can be easily brought within the reach of a mechanician, and the gearing of any group of them is mechanically much simpler and easier to move. Valuable stage space is saved by having the resistance coils in the cellar. They can be made larger, the number of steps increased and the dimming of light be advanced almost imperceptibly. This system is now being copied in England. It is to be hoped that its adoption will soon be universal.

In the last decade some progress has been made in projecting scenery to replace the always somewhat hard and non-atmospheric painted back-drop. The first was the Linnebach lamp. (*See* section on *Modern* stage design.) The Tree of Knowledge in the *Garden of Eden* was projected by this lamp. (*See* illustration.) The principle is that of the shadowgraph thrown on a drop transparent sheeting. The general forms are outlined by an opaque silhouette painted in lamp-black on a glass slide about 24 by 30 in. which is then coloured and slid over a square hood containing a carbon arc light. The line divergence of the arc rays achieves the magnified projecting without the aid of a lens. For this reason definition can not be exact, and although a large space can be covered approximately 30 by 24 ft. at a distance of 15 ft., distortion begins if any wider space is to be covered. The lamp is large and difficult to conceal and cannot be shot at an angle.

The G.K.P. lantern recently perfected in Vienna is a great improvement; the plate as small as the average lantern slide is mathematically distorted so that it can be thrown from any angle or height and cover the background of the largest stage. Any drawing can be reproduced with photographic accuracy and keep the exact quality of the artist's work. Schwabe and Co., of Berlin have perfected an elaborate motor-driven lamp which projects moving clouds and similar effects with remarkable realism. But such efforts are unimportant to current stage-craft except for certain traditional interpretations of operas.

The control of the colour of light is still in a primitive and experimental stage. Light is coloured by a series of gelatine slides placed over the spot-light lens. But the colour steps are a crude series of yellows (light dark and medium amber), a few pinks, and greens and three or four blues. Gelatines fade quickly. The colours are not standardized. Glass slides which obviate these disadvantages are not produced on a commercial scale except in Germany. The relation of the colour of lights to the dyes of materials and paint has not yet been worked out. The only scientific step has been a number of systems for illuminating the sky-drop by three-colour systems of light primaries. Red, blue and green being the light primaries, with a proper mixture of groups of all three, *i.e.*, by dimming one group or another, the colour on the sky can be moved through the entire range of the spectrum if the colour mediums used are spectroscopically pure. These have not yet been produced on a commercial scale. The present range of colour is only approximate. But the Schwabe or A.E.G. in Europe, the Pevear system in America are an indispensable unit in theatre equipment.

The Cyclorama.—Another necessity in the average theatre is the cyclorama as a substitute for the sky-drop, in open-air scenes, the angle of sight from each side of the house being such that a third of the audience can see past the ends of a sky-drop into the wings of the stage. A cyclorama is either a cylindrical expanse of canvas with an arc wide enough to block these sight lines, or an arched plaster dome that covers the whole stage. The drawback of the canvas cyclorama is that it usually hangs in wrinkles; the plaster dome blocks the use of the gridiron except on exceptionally large stages. Both Hazait and Linnebach have perfected a wrinkleless canvas cyclorama that unrolls in 1½ min. like an upright window shade, on an overhead track. These are driven by motor-power and leave the stage entirely free for shifting and striking of settings. But either these or the plaster dome in conjunction with a good system of light primaries, produce the necessary illusion of infinite depth of sky, the ambient of open air, and the subtle gradations of colour necessary to outdoor settings.

A gridiron with properly counterweighted lines, used if possible in conjunction with a revolving stage or sliding stages, a cyclorama, a three-colour border for lighting it, an ample array of focusing spot-lights on dimmers flexibly controlled by a large dimmer-board constitute the present day stage equipment which producers and designers must use. (*See* THEATRE: *Modern Tendencies.*)

(L. SI.)

STAGE LIGHTING

The function of coloured light in the theatre is to stimulate the imagination and excite the emotions of the audience. In this use it is parallel to the function of music. If the audience is in a receptive mood—fertile soil to receive and react to the impressions and atmosphere—there are two great mediums with which to achieve these effects: light and music.

Assuming that the director is familiar with the possibilities as well as the limitations of every piece of equipment used in stage lighting, he has to consider the colours at his disposal; the emotional values attributed to each; the relative strength of each colour; the effect obtained by their isolation, succession or combination. He may use coloured lights upon a stage as a painter uses his brush and paints. He can tell a complete story with lights. By the employment of the appropriate colours he can interpret the rise and fall of the emotional scale, using lights to emphasize or heighten the emotional climax.

Considered from the most elementary aspect, light may be said to have two primary purposes: brought upward, or brightened, it elevates, inspires and stimulates; taken down, or subdued, it creates a depressing, quieting or narcotic effect in the same proportion. With various shadings, gradations and combinations of colours, a certain mood may be produced in an audience. Each colour possesses a property which will create that mood or contribute to its creation.

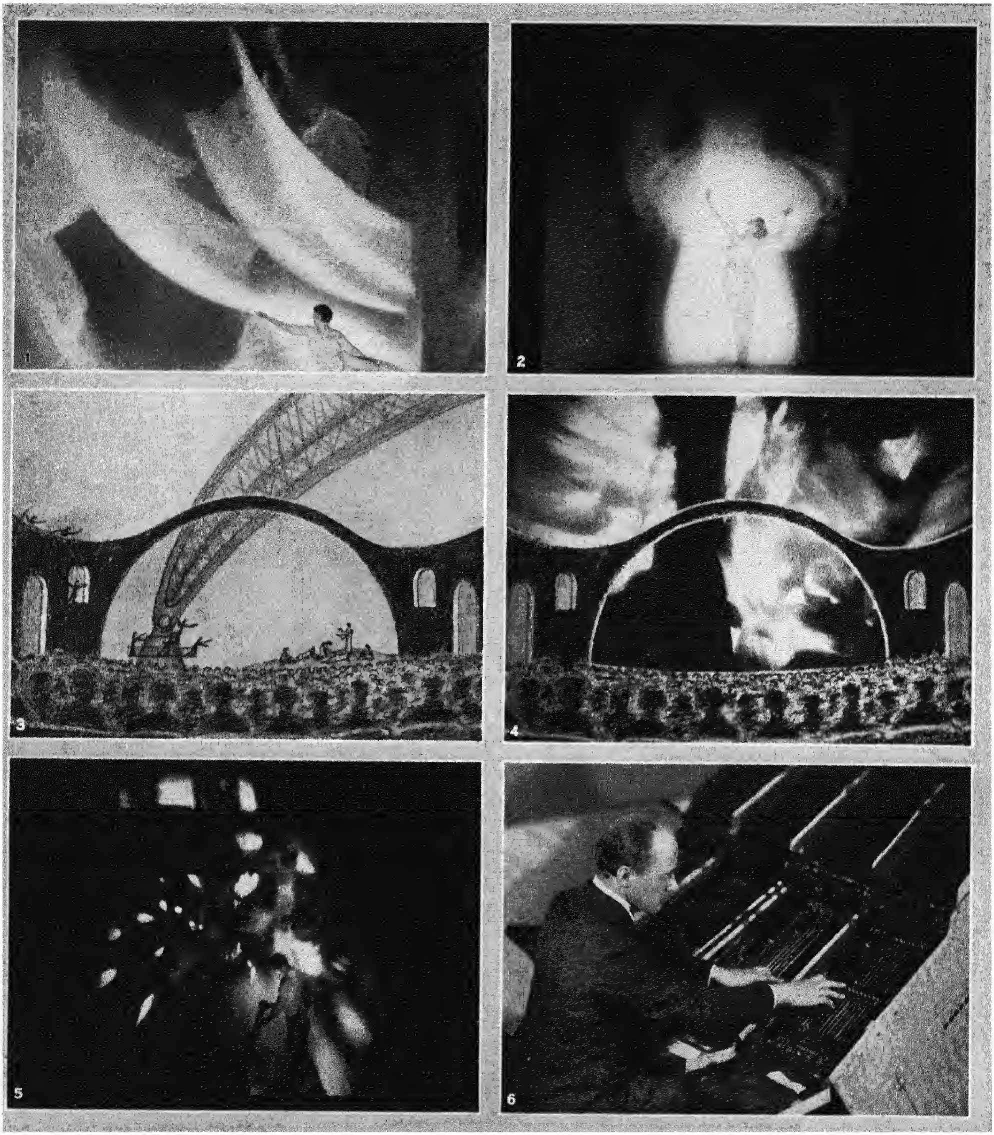
Roxy theatre switchboard, 8 ft. high nd 22 ft. long, with over 1,000 switching levers and 500 dimmers. 3. The ector room of the Roxy theatre where rector dimmers and contactor switches are placed. The rector plates run up to a capacity of 15 000 watts each, and each switchboard dimmer to 3,600 watts. 4. Spotlights placed on the bridges at each side of the stage, an effective means of creating angle lighting

STAGE DESIGN



BY COURTESY OF THE CLAVILUX LABORATORIES

COLOUR LIGHTING AS A VITAL ELEMENT IN MODERN STAGE DESIGN

1. Dancing with visual accompaniment. The dancer moves in silence with the rhythmically changing light forms as the only accompaniment
2. Changes in form, motion and colour of the luminous column, which seemingly envelops the dancer, follow the progress of the dance
3. Theatre for the use of light-settings. Screen and dome merge to form a huge surface for projected scenery. Only the base upon which the actors stand is real, the rest of the steel structure being projected from the keyboard
4. An example of the complete change in mood of stage and auditorium accomplished by the light-keyboard in a few seconds
5. Projected setting for a play. The lever which the actor grasps is actual, but the machine with its turning wheels is built up and controlled from the light-keyboard
6. The light-keyboard in the orchestra pit from which a player controls all visual possibilities by moving the small sliding keys. These, through relays, actuate the remote optical and electrical units

For example, red will excite, will create a premonition of impending danger; or it may be used to achieve a sinister effect. Amber and white added to the red will eliminate the more formidable aspects of the colour and create an effect of speed and action. Yellows and reds with a supplementary white will create a sustained mood, and serve to establish a definite atmosphere. Blue creates suspense. The audience becomes keyed to a mood It becomes interested in the succeeding action. A mixture of shades of this colour will create a subdued mood, or even depression. Purple will impart an atmosphere of majesty, of power, of magnitude. Toned amber will contribute to the effect. The use of the primary colours, red, blue and green, will create a mood of passion; of primary emotions; of strength and virility.

Thus we see how each individual colour can either definitely express a mood or be used in conjunction with another or other colours to achieve a particular mood. The intensity, proportion and quality of the colours may be modified to suit the finer gradations of the mood.

An audience cannot be thrust into the atmosphere of a particular colour, or transferred from one mood to another too abruptly. The speed or tempo must be judiciously timed to correspond with the character of the mood. Otherwise the ultimate purpose of the lighting is apt to be defeated. For this purpose, the dimmers on the switchboard, which bring up or take off the lights at the required rate of speed, demonstrate their usefulness.

The relation of coloured light to music follows the same general principles of emotional interpretation It is altogether possible to take a musical composition and interpret it by means of light, by establishing an accompanying atmosphere; to interpret the variety of moods; to mark the changes in tempo, quality and volume; to heighten or emphasize the climaxes. The analysis of colour as indicated above will serve as a guide to the interpretation of the emotional qualities of the music. A brief specific application of the theory will explain this.

The orchestra has tuned up and is ready to start the overture. It is necessary to secure the attention of the audience; to concentrate its eyes and ears on the orchestra The mechanical equipment is used to accomplish this end. The major illumination is to be thrown on the orchestra. The house lights are brought down. The musical composition to be played provides the atmospheric theme, so to speak, of the lighting. With the spotlights in the ceiling or dome of the auditorium we may throw the desired light or colours on the orchestra itself. The other lights in the ceiling may be selected in colours necessary to establish the opening character of the music. Behind the orchestra is the stage curtain, an ideal background for the light interpretation of the music. A combination of spotlights or colours may be used for this background.

By means of this picture of light, the attention of the audience is focused on the orchestra, and a suitable atmosphere is created for the music. As the composition progresses the colours may be modified, added to, changed, or intensified in accordance with the tempo, the spirit, the volume of the music. We co-ordinate the colour scale with the changing music until we reach the climax. With the approach of the finale and the marshalling of all the musical forces, the lights expand accordingly If the subdued nature of the composition requires it, the lights are likewise diminished. The closing chords find both the music and the lights finishing in perfect co-ordination

The stage picture, which is often a visual interpretation of the music, provides further means of establishing and co-ordinating the mood of the audience. Just as a composition has a definite theme or character, so the corresponding lighting of the music must have a theme. Once having determined the light theme, so to speak, it should be followed throughout the sequence to sustain that particular mood. The light that is visible to the audience is reflected light, and its purpose is to simulate reality. Thus, it is necessary to achieve, or approach as nearly as possible, a natural lighting, or a lighting that is consistent with the character of the subject or scene, and an effort should be made to emphasize the natural colours of each particular subject or scene, which provides a guide for the kind of lighting.

Costumes, materials, natural settings, may also supply the keynote for the lighting, and may be accentuated or subdued to fit the particular needs of the director.

It is often undesirable to create a specific light theme. The music or subject may not be indicative of any particular atmosphere or mood. In that case, a certain freedom in the application of colours and light may be applied.

In projecting lights, there is also the quality to be considered. Light may be hard or soft, and the resultant effects naturally are dependent on this important factor of quality. By straining the light through a filter, a diffused quality is produced, which is very effective in the establishment of atmosphere It is also important to retain the neutral character of the background or auditorium The lighting of this background must not conflict nor detract from the stage picture or music picture to be created. The maximum utilization of the different types of lighting equipment will be of further assistance in the creation of moods and atmosphere. Many different types of equipment constitute the lighting tools used in the modern theatre, but they can be condensed into two general classes: (1) general lighting, (2) localized lighting.

Modern Lighting Equipment.—The general lighting equipment consists of footlights, border lights and strip lights. Localized lighting equipment includes bunch or flood lights, incandescent spotlights and carbon arc spotlights. The localized group can further be divided into fixed units and portable units.

Lighting units placed in the foremost part of the stage may be used to illuminate the stage curtains and drapes as a musical setting, or to furnish general illumination in the foreground of the stage. Another set of units at the back of the stage is generally used for the lighting of the cyclorama or backdrop

General illumination, furnished on the stage from overhead, is the function of border lights. The stage is divided into entrances, and over each entrance, spanning the width of the stage and about 7 ft. apart, these border lights are suspended and so arranged that they can be raised and lowered at will High wattage lamps are placed in individual reflectors and are divided into colour groups, wired similarly to the footlights. Colour screens of glass or gelatine are used in border lights

Bunch or flood lights are made in many forms, and are used to light a given area to a higher intensity, or to flood painted scenery with a diffused, an unmodified or a coloured light Some flood lights are made so that they can be suspended The spotlight may be used to focus the attention of the observer to any particular performer or group, or to any one part of the scene There are innumerable points in the theatre where these spotlights can be placed, not only on the stage but out in the auditorium as well. This, however, is a very dangerous form of lighting, and must be applied with great discretion.

Bridges spanning the whole width of the stage are suspended at various places, and are mounted with a number of incandescent and arc spotlights. From them shafts of light may be directed to parts of the stage that require particular illumination Bridges are also suspended on each side of the stage, extending from the proscenium arch toward the rear wall They are built on two levels and are equipped with a number of bunch lights, incandescent spotlights and arc spotlights. The proscenium spotlights, which are nearest the proscenium arch, can also be supported on these bridges.

The unique, the grotesque, or stylized mood may be obtained by lighting at angles Lights may be focused from any direction on the desired object. The effect is generally interesting and unconventional.

It must not be forgotten, however, that the function of light in the theatre is to stimulate the imagination. In visionary lighting—the realistic appearance of dreams, apparitions and similar creative pictures—the imaginative thought is transposed to actual vision. Ceiling and side-lights are manipulated to create the illusion and the reality—food for the audience's imagination.

There are other mechanical devices to create the illusion—the simulation of various natural phenomena—rain, waterfalls, ripples, snow, etc. It is also possible to give the illusion of motion and depth to a scene. All are created by the manipulation of lights and colours. Modern equipment has made rapid strides in the

development of stage lighting, both from the mechanical and artistic standpoint, and there is every indication that in the near future it will take a much more prominent part in stage and musical interpretation than ever before.

The beauty and magnitude of this branch of the interpretative art lies in the fact that there are no limitations—no specific rules for the director to follow. He may use his ingenuity and his imagination to the full extent. It is a field where the pioneer and experimenter will reap his reward in the beauty of his creation. VISUAL ACCOMPANIMENT IN LIGHT

With the new use of light as an independent medium for aesthetic expression through form, motion and colour and the consequent beginning of an art of light (*see* COLOUR MUSIC), a promising field is opening up to artists and experimenters whose work in the new medium will, without a doubt, deeply affect the older art forms, particularly music and the arts of the theatre.

Visual Accompaniment to Music.—From Castel (1688–1757) up to the present day a considerable number of experimenters have attempted to assign a permanent colour to each step in the musical scale, but the results in actual performance have been without scientific or aesthetic justification, partly because the claim that a physical correspondence exists between sound and light vibrations has been permanently disproved by the physicist, and partly because only formless colours were employed and the absence of form and motion, the two most important factors in all visual experience, proved too great a handicap.

The only reasonable solution seems to be the complete liberation of the visual artist to compose, in form, motion and colour, a visual accompaniment to an already written musical composition and of the musician to compose similarly in melody, harmony and rhythm a musical setting to a silent visual composition with all the freedom he now has in setting a poem to music.

One of the first attempts in this direction was demonstrated by Leopold Stokowski and the Philadelphia Orchestra and Thomas Wilfred and his clavilux (*q.v.*) in Carnegie Hall, New York in Jan. 1926. For each of the four movements of Rimsky-Korsakov's "Scheherazade" Wilfred had composed a mobile visual setting which he played on a large white screen erected between the orchestra and the auditorium. Each musical motif had a corresponding mobile form and colour motif and these were blended and interwoven as the music was played. It was here demonstrated that an aural crescendo can effectively be accompanied by a visual diminuendo and also that the so-called cool colours (blue, turquoise and green) introduced in definite forms in certain rapid motion progressions, can well be used with an aural climax which invariably would have suggested "red" had only formless colour been employed. Form and motion alone have also been used in mobile white, grey and black accompaniments to music.

Visual Accompaniment to the Drama.—The art of light also opens up fascinating possibilities in the use of mobile light-settings of abstract, symbolic or even realistic nature which will fold themselves around the action of a play, opera, pantomime or dance as closely as music around a poem—so delicately blended and changed that the spectator, while aware of the unusual emphasis it would give to every scene, would seldom be conscious of the lighting itself.

But before such possibilities can be touched upon it will be necessary to revise the entire lighting system of the theatre. Even the most elaborate of the present day equipments are still manipulated by the electricians from large cumbersome switchboards, generally so placed in a corner of the stage that the several operators are unable to see the results produced. This switchboard should be replaced by a light-keyboard placed in the orchestra pit or in a modified prompter's box under the front part of the stage from which the light-artist can control all visual possibilities by the sweep of a hand over tiny low voltage keys. Furthermore, a standardization of lighting units and keyboards must be arrived at in order to permit the playing of a written light-score in any theatre without the necessity of transporting the heavy and delicate equipment as is now the practice.

Having the manuscript of the play before him and using the white cyclorama or backdrop as a painter's canvas the scenic artist at the light-console can then proceed to illuminate the actors and the necessary material units, at the same time building up, from special projectors, mobile visual settings in apparent space surrounding the action and recording it all in a suitable notation below the lines of the play. Settings projected in light have been used for many years, generally painted in colour upon glass or mica disks which were then rotated in the focal plane of a powerful stereopticon, but only on rare occasions have these been executed by the scenic designer as an integral part of the setting. They have mostly consisted of detached "effects" such as drifting clouds, water ripple, etc., superimposed upon already painted drops, and the results have lacked co-ordination and depth.

Adolphe Appia, the first important pioneer in stage lighting, writes in his *Die Musik und die Inscenierung* (1899) about the forest scene in "Siegfried": "We must no longer try to create the illusion of a forest, but instead the illusion of a man in the atmosphere of a forest. When the forest trees, stirred by the breeze, attract the attention of Siegfried, we, the spectators, should see Siegfried bathed in the moving light and shadows and not the movement of rags of canvas agitated by stage tricks."

With the invention of the clavilux the projection and control of three-dimensional form in motion has become possible and this instrument was used in the production of Ibsen's "The Vikings" at the Goodman theatre, Chicago, in March 1928. Each of the four acts began and ended in complete darkness and out of this forms and figures were lifted only as they were meant to occupy the attention of the spectator. The second act, a nocturnal banquet of vikings in a Norse hall, was lit entirely from a battery of instruments in the central fireplace, and mobile firelight, slightly stylized, followed the action, constantly bringing out areas of importance while subduing all else, increasing and decreasing in intensity and tempo and retarding only once into a static glow to intensify a moment of suspense. The light conditions changed so constantly during the entire act that the player was unable to lift his hands from the light-keyboard for a single moment. The ride of the dead warriors to Valhalla, generally obtained in opera by moving lantern slides, was here done as an abstract essence of blackness galloping toward light amid flashes of steel and blood.

Thus lighting, having assumed equal importance with music in the theatre, will need a new type of creative artist whose main task will be the fusion of the movements of actors and groups with the space surrounding them in such a way that the two come to form a mobile, at all times perfect, frame around the spoken word. The lighting of static settings and the more or less independent "flooding" and "spotting" of the actors will give way to the one difficult problem: *the aesthetic treatment with light of mobile form in space.*

The New Stage.—It is probable that such progress will greatly simplify the mechanical requirements of the stage of to-day, at the same time permitting such freedom as the gradual change from one scene or act to the next without a break or a single mechanical operation. The new stage in its simplest form would then merely consist of a raised platform in front of a large white surface. No proscenium or curtain would be required as the proper use of light would frame each scene and darkness mark the beginning and end of each chapter of the play, the conventional division into acts and scenes no longer being necessary. Such a stage has been evolved by the American designer, Norman Bel Geddes.

It will be well for those who are to build the theatres of the future to reflect over Appia's prophetic words, uttered in the closing years of the last century: "An object or an actor takes on a plastic quality only through the light that strikes it, and the

plasticity can only be of artistic value when the light is artistically handled." (*See* also LIGHTING AND ARTIFICIAL ILLUMINATION: *Lighting in Practice.*) (T. Wi.)

STAGGER PLAN. The great congestion of transit facilities in some of the larger cities of the United States, due to a uniformity of opening and closing hours, has led to the adoption of a so-called stagger plan. The acuteness of the problem in the city of New York is mainly due to the large number of persons involved, to the fact that business areas are highly concentrated as the result of tall buildings and to the fact that travel is confined largely to two directions, owing to the shape and geographical location of the island which forms the centre of New York's business activity. The department of health, feeling that the congestion of the transit facilities constituted a menace to health, conducted a survey to determine the feasibility of "staggering" or varying the opening and closing hours of firms employing large numbers of persons. As the result of this survey, a plan was determined upon and a considerable number of organizations voluntarily agreed to shift their opening and closing hours in conformity with the recommendations of the health department. Some of the larger companies found it desirable to divide their employees into groups, one group arriving at 8.30, another at 8 45, another at 9, another at 9 15 and another at 9 30. Each of these groups leaves at correspondingly different times in the afternoon The groups are chosen in such a manner as to be co-ordinate with the flow of work in the organization. In addition to relieving congestion on the transit lines, this also tends to relieve congestion in the halls and elevators of the company's building. The movement was in 1928 still in the embryonic stage. (O G S)

STAHL, FRIEDRICH JULIUS (1802–1861), German ecclesiastical lawyer and politician, was born at Munich on Jan. 16, 1802, of Jewish parentage At the age of nineteen he entered the Lutheran church. He was professor of law at Würzburg, and of ecclesiastical law and polity at Berlin. Stahl early fell under the influence of Schelling, and at the latter's insistence, began in 1827 his great work: *Die Philosophie des Rechts nach geschichtlicher Ansicht* (an historical view of the philosophy of law), in which he bases all law and political science upon Christian revelation, denies rationalistic doctrines, and, as a deduction from this principle, maintains that a state church must be strictly confessional. This position he further elucidated in his *Der christliche Staat und sein Verhältniss zum Deismus und Judenthum* (The Christian State and its relation to Deism and Judaism). As synodal councillor Stahl made use of his influence to weaken the Evangelical Union (*i e.,* that compromise between the Calvinist and Lutheran doctrines which is the essence of the Prussian Evangelical Church) and to strengthen the influence of the Lutheran Church (Cf. *Die Lutherische Kirche und die Union,* 1859) Frederick William IV. supported Stahl in his ecclesiastical policy, and the Prussian Evangelical Church would probably have been dissolved had not the regency of Prince William (afterwards the emperor William I.) supervened in 1858. Stahl retired into private life and died at Brückenau on Aug. 10, 1861.

STAHL, GEORG ERNST (1660–1734), German chemist and physician, was born on Oct. 21, 1660, at Anspach Having graduated in medicine at Jena in 1683, he became court physician to the duke of Weimar in 1687 From 1694 to 1716 he held the chair of medicine at Halle, and was then appointed physician to the king of Prussia in Berlin, where he died on May 14, 1734 In chemistry he is chiefly known in connection with his doctrine of phlogiston (*see* CHEMISTRY, *History of*), the essentials of which, however, he owed to J J Becher; and he also propounded a view of fermentation which in some respects resembles that supported by Liebig a century and a half later.

STÅHLBERG, KAARLO JUHO (1865–), Finnish statesman, was born on Jan. 28, 1865. At the beginning of his public career, he held alternately university and administrative posts until he became a member of the Diet in 1904 and of the Finnish Government in 1905. He resigned in 1907 and in the following year was appointed a professor of administrative law. At the outbreak of the World War, the government was Finnish in name only, being composed entirely of Russian officials Ståhlberg was then president of the Diet and he had to act as the chief public representative of Finnish opinion He firmly withstood the increasingly oppressive tendencies of the Imperial Russian Government. After the Russian revolution of 1917 Finland became an independent republic, and in 1919 Ståhlberg was elected to the presidency and as the candidate of the Progressive and Socialist parties he had to fight the unconcealed hostility and distrust of the conservative parties. He pursued, nevertheless, a conciliatory and mitigating policy, and when the time of the next presidential election approached, the country almost unanimously desired him to accept re-election. He refused, however, and retired on the expiration of his presidency.

STAINED GLASS, a term that is generally understood to refer only to glass windows that have been coloured by such methods as the fusion of metallic oxides into the glass, the burning of pigment into the surface of white glass, or the joining of white with coloured pieces of glass

ORIGINS

The origin of stained glass is obscure. It probably came from the Near East, the home of the glass industry, and mosaic windows of glass set in plaster work, which we know from the 17th century in Egypt and elsewhere, are probably of great antiquity But it is not likely that the art goes farther back than the 9th century; it is doubtful if before that time glass was made in a sufficient variety of colours to suggest and produce coloured designs. The art would most naturally spread first to Italy, and Venice may have been a centre as early as the 10th century. An Italian panel in the Victoria and Albert Museum, tentatively ascribed to the 13th or 14th century, is fully Italian and Romanesque in style and suggests a native tradition. Actually the earliest reference to stained glass in the accepted sense of the term (that is, windows not merely coloured, but pictorial also) is in a manuscript which records that Adalbéron, bishop of Rheims from 969 to 988, rebuilt the cathedral and redecorated it with windows representing various stories (Richer, vol. ii., lib. 3) An earlier reference, in a 9th century life of St. Ludger, certainly relates to coloured windows, but it is not clear that they were pictorial. Mâle gives, as the earliest mention of leading, a reference to the *Miracles of Saint Benoit* where it is related that in the last years of the 10th century the church of Fleury-sur-Loire was set on fire and it was feared that the leads of the windows would be melted. Which are the earliest windows extant is a matter of dispute, but the evidence, both literary and stylistic, seems to favour certain figures of prophets in Augsburg cathedral, which may date from the middle of the 11th century

TECHNIQUE

A stained-glass window is a translucent mosaic held together by lead; that is the simplest conception of its technique Actually other considerations come into play in the design and execution of a window. The lead is not merely a connecting medium, but in all good design plays a part of its own; it outlines the main constituents of the design, giving definition and rhythm to the masses of colour From the account given by Theophilus, we can derive a very accurate notion of the technique as practised when the art first came to its perfection in the 12th century. The general scheme for the glazing of a church was, of course, the care of the clerics, and we may assume that the artists among them, the illuminators, would prepare the first drawings One such series of drawings, the Guthlac Roll, is preserved in the British Museum (Harley Roll, Y 6) But the actual cartoon for the glass was drawn on one end of a whitewashed board supported on trestles The vacant space at the other end was used for laying out the glass and for the general business of glazing The cartoon was marked to indicate the various colours, and the next step was to shape a piece of glass to the outline required by the design. This was done, firstly and roughly, with a hot iron and then more carefully with a tool known as the "grozing iron," a flat piece of iron with a notch at one end, rather like a modern spanner. This must have been a slow and laborious process, but the grozing iron seems to have continued in use until about 1500,

when the modern method of diamond cutting began to be employed. The next step, in a fully developed stained-glass window, was to paint the glass with details which the bare design of glass could not give. At first the use of paint was confined to an opaque brown (grisaille, *q.v.*), used, not as colour, but as a means of outlining the design in further detail, reinforcing the effect of the leads. This pigment consisted of powdered glass mixed with a metallic oxide (probably iron), to which was added sufficient gum to make the mixture adhere. If "high lights" were desired, the whole surface of the particular piece of glass was covered with a thin coating of this paint and the lines scratched through with a pointed stick. Shading effects were produced by stippling with a brush. The glass, having been painted, was next fired in the kiln, to fuse the enamels to the glass. In mediaeval times the glass was fired in a pan, which was filled to the top with alternate layers of glass and whiting. When the glass was fused sufficiently, it was brought out and cooled and then rearranged on the glazing table. The next step was the leading. This was (and still is) done by means of strips of lead, in section like the letter H, but with a thicker cross-bar to represent the "core" of the lead; the upright strokes represent the "tapes." At first the leads were cast, but in the 17th century the lead vice was introduced. This is a kind of mangle, with two toothed wheels like coins with milled edges, between which a strip of lead is squeezed, the soft metal emerging in the form already described. Sometimes the wheels had the glazier's name engraved on them, which thus became impressed on the lead as it passed through the machine, and these names are occasionally found on old leading. When the leads, cut to the required length and shape, had been inserted between the pieces of grozed glass, they were next soldered together at the points of junction, and cement or putty was rubbed into the crevices between glass and lead. The window was then ready to move into place, where it was fixed by means of copper wires soldered to the leads and attached to iron saddle-bars let into the masonry. Larger windows were made in smaller units and these units fitted into an iron framework or "armature" which itself often formed a geometric design contributing to the general effect of the window.

From the 12th to the 15th century the technique of stained glass remained practically unchanged, though one minor innovation had a great effect on the character of design. This was the invention, early in the 14th century, of a yellow stain derived from a solution of silver. It formed a very thin film on the glass and was therefore very transparent; on clear glass it varied in tone from pale lemon yellow to deep orange; but it could also be applied to blue glass to produce a brilliant green. Its effect on design was far-reaching and will be noticed when we come to the history of the craft. In the 16th century the technique of glass-painting became more scientific; the glass itself was thinner and smoother and more transparent; two layers of different colours could be put together to produce a third colour; if these layers were fused together, one layer could be ground away or "abraded" (and by a later process "eaten" away by fluoric acid) to give delicate effects beyond the reach of a leaded mosaic. Finally, towards the middle of the 16th century, the art of painting in enamel on glass appeared, perhaps as a result of economic causes which made a scarcity of pot-metal. Hitherto glass had been coloured throughout its substance and was known as "pot-metal," though to obtain sufficient translucency in a dark colour like ruby the glass was "flashed," that is to say, clear glass whilst still pliant was dipped into molten coloured glass, and so received a translucent film of the desired colour. But now ground glass was mixed with various metallic oxides (copper for green, cobalt for blue, manganese for purple, and so on) and the design was then painted on to a clear sheet of glass and fused on. For some time this technique was continued with the old technique of leaded pot-metal; but in the 17th and 18th centuries the old technique disappeared, and the art of stained glass was virtually dead.

HISTORY

Eleventh and Twelfth Centuries.—The windows at Augsburg, ascribed by Fischer to the middle of the 11th century, have already been mentioned. To the end of the 11th century belongs a window at Le Mans (France) painted with the Ascension. For the 12th century we have in England a figure from a Tree of Jesse in the minster at York, and at Canterbury there is a magnificent series representing the genealogy of Christ which may be dated about 1180. At Chartres there are more important and extensive examples—in the west window is a Tree of Jesse design which is undoubtedly the best surviving stained glass of this century; also the beautiful figure of the Virgin and Child known as La Belle Verrière. Other considerable specimens of 12th century glass exist at Angers, Saint Denis, Châlons-sur-Marne, Bourges, Strasbourg, Poitiers and Le Champ (Isère). The earliest of these windows, such as those at Augsburg and Chartres, are strongly Romanesque in character. The windows at Canterbury come at the end of the Romanesque tradition. They still preserve the monumentality so characteristic of Romanesque design, but the figures are far removed from the rigorously schematic treatment of the Augsburg prophets; there is the first flush of humanism in their bold features. There is a sense of movement in their limbs; a sense of vigour in the formal draperies. The colouring of this Canterbury glass is still typical of the 12th century; the bare flesh is cut in pink glass, whilst the rest of the design is a quiet harmony of blues, pale green, white, brown and yellow, arranged in fairly broad masses with no effort towards "jewel-like" quality. The architectural settings are rudimentary, in most cases representing a simple column on each side of the figure, with an arch spanning the head.

It is probable that most of the early windows were of the single-figure, monumental character of the Augsburg and Canterbury examples. But about the middle of the 12th century a new type of window came into being which consisted, instead of a single representative figure, of a medallion (or several medallions) painted with pictorial subjects, such as incidents from the life of Christ, or from the life of some saint. This change was accompanied by various subsidiary developments. The necessity of telling a story in a series of medallions led to the decorative arrangement of these medallions within an "armature" or iron framework which was itself a subject for pattern, and very beautiful designs were evolved, showing a skilful counterplay of circles, lozenges, quatrefoils and squares, with their appropriate borders and interspaces. This development in its turn necessitated larger windows and this necessity had a profound effect on the development of Gothic architecture itself. A third development was in the actual colour of the glass. The pictorial treatment called for a more detailed and more varied play of colour, and the technical resources of the glass-maker were equal to this demand. The result was that kaleidoscopic or jewel-like glow of colours with which stained glass is always popularly associated. It is in glass of the early 13th century that this property is supremely evident.

Thirteenth Century.—With these early 13th century medallions we first become fully conscious of the part played by the actual painting in stained glass. It is true that the earlier figures had a broad effective scheme of drawing, but with the 13th century medallions a fine dramatic sense of line was developed and continued in force throughout the century. And with the sense of line came that superb sense of dramatic composition illustrated in so many of the medallions of this period at Canterbury, Lincoln, Chartres, Sens, Bourges, Le Mans, Rouen, Cologne, Marburg and Klosterneuburg (near Vienna). The highly stylicized motives of the decorative borders of the 12th century were no longer in keeping with this dramatic mode, and as the century advances we accordingly get a naturalizing of these motives. The formal acanthus leaves of classical inspiration give place to more natural plant motives, to scrolls of oak and vine; these coil with a more organic and vigorous movement, until eventually, in the 14th century, the artists begin to copy directly from their own observation—from the ivy and the wild strawberry.

Towards the last quarter of the 13th century, a greyer mood seems to have descended on our glass-painters. It may be that they were required to give more light in the churches, or that the supply of ruby glass, always somewhat precarious, gave out. Whatever the reason, there developed in the latter part of the

ENGLISH STAINED GLASS

"The Patriarch Jared." 12th century window in the south transept of Canterbury Cathedral. As in much of the mediaeval glass in England, the bare flesh is cut in pink glass, while the rest of the design is a harmony of blues, pale green, white, brown and yellow, arranged in fairly broad masses

13th and early 14th centuries the technique generally known as *grisaille* painting. It implies the use of large areas of clear quarries painted in black or brown enamel with simple and unobtrusive patterns of foliage. Grisaille work at this period is of two kinds: it may consist of geometrical patterns of quarries, often outlined in coloured bands, on which are painted designs of foliage, often in imitation of a trellised plant, or it may be used in combination with subject medallions. The best instance of this latter method is perhaps seen in the windows of the Chapter House at York, which, though now much decayed and obscured, are supreme examples of grisaille work.

These characteristics of 13th century stained glass are general wherever the main stream of Gothic art (*q.v.*) flowed. Distinctions of nationality need not, and indeed cannot, be made. In point of time the medallion windows at Canterbury perhaps come first; then, closest in time and style, come the similar windows at Sens; Chartres comes next and is very impressive in its quantity and scale; at Bourges and Rouen there is glass very similar to that of Chartres; the glass at Lincoln and Beverley in England must be placed somewhere before the middle of the century. But back again in France we find a more distinctive school developing in Paris during the second half of the century, in connection with the building of the Sainte Chapelle and the extension of Notre Dame. The distinguishing feature of this latter style was the general use of a background of trellis-work in blue and red glass, which, in the mass, has a rather unpleasant purple effect. This style scarcely penetrated to England, though an example may be seen in the east window of the south transept of Christ Church, Oxford.

Fourteenth Century.—Midway in the 14th century comes the Black Death, and this catastrophe marks the end of the pure Gothic tradition, in this as in all other arts. Its most marked effect was perhaps reflected in the break-up of the inter-community of Christian art. No doubt other forces, economic or political, were operative too; but the disorganization caused by the Black Death among artists and craftsmen all over Europe resulted in the formation of more limited and more local schools. Onward from 1350 the styles of England, France, Austria and Germany diverge more and more from each other. And within all these countries the local differentiations between various centres are often very marked. The disorganization not only affected traditions, but even more so technique. It seems that the ability to manufacture some of the brilliantly coloured kinds of glass was lost at this time, never fully to be recovered until the 19th century. There was also a Franciscan ban on pictorial windows, which no doubt had some influence in this direction, during the 14th century. But the glass-painters were not slow to react to the new situation; the invention of yellow stain early in the century had provided them with one new resource; and the growing taste for line design, as witnessed in the grisaille glass already mentioned, led to the full exploitation of clear white glass. When once the use of white glass had been forced on the glass-painters, its aesthetic value was appreciated. It may be also that the resultant effect on the lighting of the churches was appreciated, and that the glass-painters began consciously to aim at a clearer effect. Architectural developments kept pace with, and even aided, this changing colour-scale. The windows grew higher and wider, the tracery more intricate, demanding of the glass-painter an effect that was not too heavy for the expanse to be filled, or too clumsy for its delicacy.

Further developments were due not so much to economic factors as to a change in spirit. The 14th century saw the full emergence of that movement towards humanism which had found its protagonist early in the 13th century in St. Francis of Assisi. The tendency towards naturalism which we have already seen creeping into the decorative motives of stained glass was a far wider phenomenon, and involved all art and literature. The new spirit of Franciscan naturalism only manifested itself in plastic art, by slow degrees, but it culminated in the Renaissance. It involved a transformation of Christian iconography, and the glass-painter, along with other artists, now deserted the fixed types of early Gothic art for the living types before him. Subjects are now given a contemporary setting; for his figures, his costumes and his architecture the painter looked around him and found models before his eyes. A playful freedom of line gradually developed; as the brush-stroke grew lighter, it grew easier. The features are rendered with more grace and verve; there is almost an excess of curve and curl in eyes and lips and locks. An individualization of the features begins to creep in; we begin to feel the presence of real people, friends and contemporaries of the glass-painter, no longer abstracted, no longer idealized. The folds of the garments lose their angular restlessness and sweep and sway in graceful curves. We get, too, the entry of fashion. The garments in the 12th and 13th centuries are formal and of classical derivation, except in so far as they are ecclesiastical or military. They continue to be somewhat non-committal during the first half of the 14th century, but with the growth of naturalistic treatment and the revival of figure-subjects we get the unmistakable evidences of contemporary fashions. The representation of costume then becomes a matter of course, and is of great assistance in the precise dating of stained glass.

But the most typical and expressive development of ornament is seen in the canopy. This form of architectural ornament no doubt originated in the 12th century, when an architectural unit —generally an arch—was introduced to indicate a building or interior scene. This simple unit became more elaborate during the 13th century, but remained essentially illustrative in intention. Then we get as an early characteristic of the 14th century, the elaboration of this detail into purely ornamental features. The architecture is given the value of pure decoration. At first this is rendered in one dimension, and slender pillars and fretted pinnacles, interchanged in colour, form a simple and effective setting for the figures within the framework. But as the architecture itself becomes more elaborate, its representation in the glass develops. By the end of the 14th century we find an elaborate use of perspective. In the 15th century the spirit of play breaks out even here, and the niches are peopled with angels and coy minstrels. As the century advances the canopies grow more complex, though more representational.

Fifteenth Century.—With this development of the architectural features of stained glass ornament is perhaps bound up a curious retrogression during the 15th century—the abandonment of natural plant motives for stylicized diapers. Artists forsook the carefully observed ivy, oak and vine, and introduced instead such dreary motives as that usually described as the "seaweed pattern"—an elongated, shapelessly indented leaf, generally painted in reserve on a blue or ruby glass, and seemingly kept as "stock" to be used whenever the design required an indeterminate background. It was a step towards that still more slipshod expedient—the stencilled diaper background of the 16th century. The borders, which had always been an integral part of stained glass design, develop in conformity with the general trend. But their aesthetic function becomes less obvious and they gradually lose decorative value. In the 12th century the border had been the essential framework of the design, enclosing within its definite pattern the otherwise unconfined design. In the 13th century the border existed as a foil for the sequence of separate designs. Then, in the 14th century, when the subject-panel became isolated from its background, the border became a purely decorative feature, contributing a separate unit to the general aesthetic effect; in the 12th century the border framed the design—in the 14th it edged the frame of stonework, its naturalistic form suiting this purpose admirably. Then in the 15th century, with its strange efflorescence of canopy work, the border tended to lose all aesthetic justification; it existed merely as a strip dividing the design from the stonework, and providing, as it were, a transition from one to the other. In this rôle it naturally tended to become more formal in character. Already in the 14th century the typical border of creeping foliage had been varied with alternations of devices such as crowns, chalices, heraldic badges, grotesque animals, small figures of angels, etc.; an exceptional example is to be seen in the famous Bellfounders' window in the north aisle of the nave, York minster, where the border consists of bells (outer lights) and musical monkeys (centre

light). The 15th century saw some recovery of the sense of colour. Coloured glass of a variety of colours, but too even and flat in tone to be quite satisfactory, became available on the Continent and was largely imported into England. Already in 1408 the east window at York minster, made by John Thornton of Coventry, is full of a new vitality and gaiety. The covenants for the execution of the glass in the Beauchamp Chapel, Warwick, which are dated 1447, specifically provide for glazing the windows "with Glasse beyond the Seas, and with no Glasse of England; and that in the finest wise, with the best, cleanest and strongest glasse of beyond the Sea that may be had in England." This window was carried out by John Prudde, one of the greatest of English glass-painters, and the result is versatile in the extreme, the colours, jewelled and counterchanged to the utmost limits of ingenuity, blazing with the greatest richness imaginable.

In Germany also, the development was in consonance with the richness and complexity of late Gothic art in general, and here the development may be particularly associated with the name of Hans Wild, whose principal works date from about 1470 to 1480. His most famous window is in the cathedral at Ulm, and shows great boldness and original fantasy in the use of foliage motives. The window becomes a luxuriant trelliswork of flowering plants and pinnacles in the depths of which the human figures tend almost to disappear.

One characteristic of this period is the development of heraldry in glass. We have practically no knowledge or records of the use of heraldry in stained-glass windows previous to the 14th century, though there are three 13th century shields in the apse windows of Westminster Abbey which serve to indicate an early use of heraldic glass. We know from records that these shields were originally placed in the aisle windows, which were of grisaille. But the particular circumstances which brought heraldic glass into general use are hardly consistent with the spirit of early Gothic art. One of the characteristics of the 14th century is the introduction of the personal element into the windows. Donors began to desire their portraits within the design of their window; memorials to the immediate dead began to assume a representational form. At first no attempt at faithful portrayal could be made; the mode and technique of glass-painting at that time forbade it. The shield of arms had therefore the very definite use of identification. But it was soon realized that heraldry had an aesthetic value of its own, and its use multiplied. Glass proved to be especially suitable to the rendering of the formal patterns of the shields, and the brilliancy doubly attractive in this personal emblem. The ground of the shield, which was usually filled in with a diaper pattern, gave the glass-painter an opportunity to exercise his skill in brushwork and his fertility in the invention of decorative motives. The technique of scratching a design with a point through a dense ground of colour, always a pleasant technique in glass-painting, was encouraged by this development. The glass-painter kept pace with the herald, and did not hesitate to attempt the utmost elaboration of curved shield and exuberant mantling. With the Renaissance heraldic glass took on a more restrained appearance—at least, in England, where the common use of the garter and the wreath tended to confine the design within sober limits. Elsewhere, especially in Switzerland, heraldic glass became, during the course of the 15th and 16th centuries, the most typical use of glass-painting.

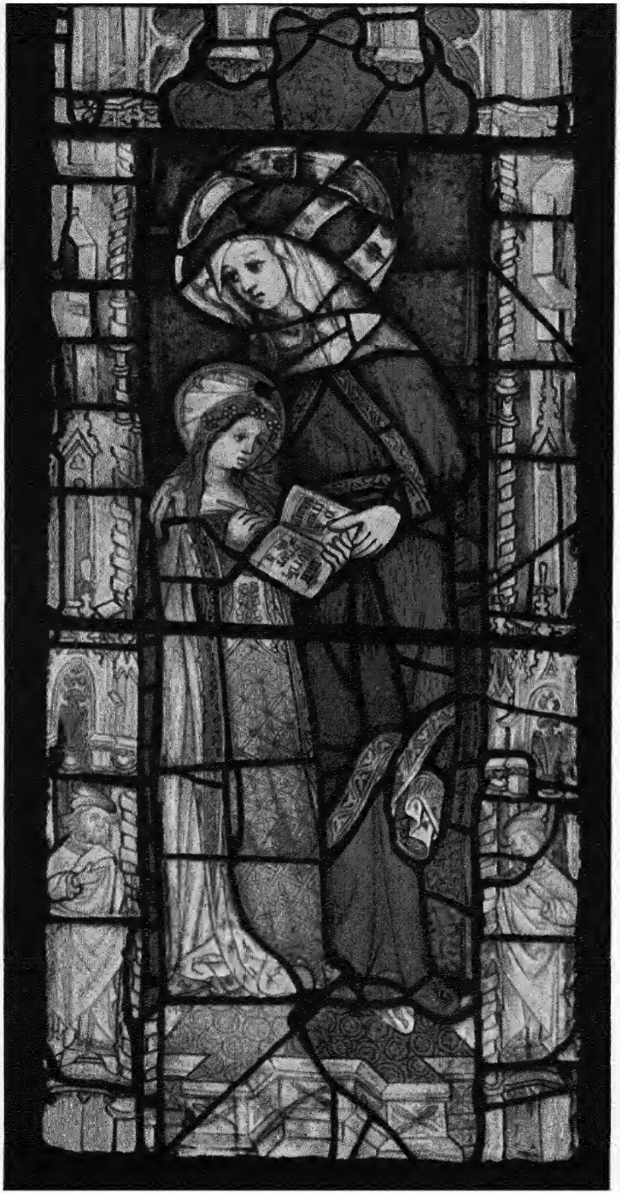
The 15th century saw a great growth and intensification of the individualism we have already noted as arising in the 14th century. Such a development naturally gave rise to the dominance of artists of unusual talent, and to the formation of schools dependent on such artists. A distinct style became established as a local tradition and sometimes persisted over two or three generations. Such schools were formed all over Europe, and particularly in the great ecclesiastical cities. In England, for example, definite schools can be associated with York, Coventry, Canterbury, Winchester, Oxford, Gloucester, Wells, Lincoln, Norwich and Westminster.

The different styles are not always easy to distinguish, and the "schools" are rather in the nature of empirical groupings based on the density of distribution.

Towards the end of the 15th century England suffered a general invasion of foreign artists and craftsmen, a growing influx that reached its culmination early in the next century with the arrival of Torrigiano and Holbein. At this time, in the Netherlands, the art of stained glass had reached a development which, in accomplishment and modernity, was far ahead of the insular style in vogue among English glass-painters. The wool and cloth trades flourished in spite of the wars. The new merchants, earnest Lollards as they were, were eager to turn their wealth to some good purpose, and thus they made the 15th century an age of church building and charitable foundations. And these merchants, moreover, were men of some culture, whose business had brought them into contact with foreign luxuries—particularly those of the Netherlands. When, therefore, they required glass for the beautifully furnished churches which they began to construct in various parts of the country, they demanded glass in keeping with their luxurious tastes, and for this they turned to the men from the Netherlands. In answer to the demand these men came across and, in accordance with the regulations, established themselves within a recognized sanctuary such as the liberty of St. Thomas in Southwark, and assumed English names. As time went on, they became a menace to the existence of the London Company or Gild of Glaziers, and a continual series of disputes between the Gild and the foreigners marks the beginning of the 16th century. But the proper tradition of glass-painting was entirely lost. In the middle ages stained glass thrived as an art subordinate to, or in community with, architecture. With the Renaissance, and the shifting of the dominant emphasis of artistic effort from architecture to painting, the glass-painter found himself in a dilemma. He had to adapt his art to the new conditions, or suffer from the general neglect of arts subordinate to architecture. He attempted to save himself by adopting the aesthetics of painting, and the history of stained glass henceforth is the history of this false step and of all the disastrous consequences.

Sixteenth and Seventeenth Centuries.—But whilst this false aesthetic was developing, there grew up in France and the Netherlands a full-blooded Renaissance style of glass-painting which makes the first half of the 16th century a distinctive epoch in the history of the art. It is a development of the pictorial treatment of the windows on the largest possible scale; the window is regarded as one large canvas; the intersecting mullions are ignored. On this canvas the coloured glass is spread in generous masses and heightened by all the resources of line and shade. The windows gleam with everything that is rich and ornate in colour, design and subject. The glass is thin, but this fault is counteracted by the breadth of the treatment. The Netherlandish type is well represented in England by the work of imported artists, of whom Barnard Flower is the most important. This artist came from the Netherlands, probably encouraged by Henry VII., who made him king's glazier in 1505. Flower executed the whole of the windows for Henry VII.'s chapel at Westminster, and was entrusted with the contract for King's College chapel, Cambridge, but died before he had completed more than four of the windows. It is probable that among the work which may be attributed to Flower are the windows of Fairford church in Gloucestershire, perhaps the most complete unit of stained glass remaining intact in England. King's College chapel, begun by Flower after designs probably by the Flemish artist, Dirick Vellert, was completed by a mixed company of English and Flemish glaziers.

In France, Rouen was the great centre of glass-painting, and that city still offers an incomparable display of the glass of this period, though many other towns, such as Evreux, Châlons-sur-Marne, Dreux, Beauvais, Auch, Troyes and Montmorency, are famous for their windows. In the Netherlands, the most important windows of this period are found in Antwerp, Hoogstraten, Brussels, Liége and Amsterdam, whilst the windows at Gouda, painted by the brothers Dirk and Waiter Crabeth and their pupils towards the end of the 16th century, are of extraordinary range and completeness. In Germany important schools existed at Strasbourg, Augsburg, Munich, Freiburg-im-Breisgau, Nurem-



ENGLISH STAINED GLASS

"St. Anne Teaching the Virgin." From the east window of All Saints church, York, dated about 1440. The colouring is simple though rich in quality, a characteristic of English glass of this period. St. Anne wears a ruby cloak and bonnet and a blue gown. The Virgin's dress is white, ornamented with a pale yellow pattern, and the background of figures and canopy is blue covered with a diaper. All other parts are white with some yellow stain

berg, and above all at Cologne, the general character of all of which was not essentially different from that of the dominant Flemish or French type. In Italy the period is mainly associated with the name of Guglielmo de Marcillat (1467–1529, sometimes erroneously called William of Marseilles). Windows known to have been made by him exist at Arezzo and Rome, and a very typical example from the cathedral of Cortona, dated 1516, is in the Victoria and Albert Museum. At Florence, where there are also important earlier windows in the cathedral which are said to have been designed by Ghiberti and Donatello, other windows in the style of Marcillat may be seen in the church of Santa Croce. The building of the cathedral at Milan caused an important school of glass-painting to develop there, and the work of Cristoforo de Mottios and Nicolo da Varallo carried out during the second half of the 15th century is of great beauty. The Milan school continued in full activity during the 16th and 17th centuries. In Spain, especially at Seville, León and Avila, magnificent windows of this period exist, but they are in all cases the work of Flemish glass-painters.

In the 17th century we find the highest level of glass-painting in Switzerland, though actually that level had been surpassed in its own country during the 16th century, when Holbein and Burgkmair were leading designers of the panels typical of that country. But the real significance of Switzerland in the history of glass-painting is that there alone was evolved an appropriate technique of enamel-painting. For various reasons of a social kind, glass-painting in that country had acquired a more domestic character; it actually became part of the furniture of the people, and a panel for the window of a room was as natural, and even more usual, than a picture for the wall. Glass-paintings thus became intimate and portable—a kind of *Kleinmalerei* comparable to the development of *Kleinplastik* in sculpture Within the limits of this littleness, the art of enamelling glass developed an appropriate technique It was, indeed, the technique of painting—of translucent painting—but then the Swiss panel *was* in all essentials a painting. To the same category belong the roundels painted in grisaille which were produced in large quantities during the first half of the 16th century In these types of glass-painting the specific problems of distance and architectural harmony did not enter into the question; everything was made for nearness and intimacy. And on this scale stained glass was inappropriate, ungainly and without effect

The same observations might be made of the Dutch and Flemish glass-paintings of the 16th and 17th centuries, which illustrate the enamel technique in both its good and bad aspects, and it was through these, rather than the Swiss, that the new style penetrated to England. Abraham and Bernard van Linge (who flourished about 1620–40 and painted many windows in Oxford and elsewhere) were the chief of these immigrants, but they were ably imitated by native artists such as Henry Gyles of York (1645–1709), the Price and the Peckitt families of the same city, and by artists like Francis Eginton (1737–1805) and James Pearson (d. 1805), who carried the art right on to the threshold of the 19th century. At their best, the achievements of the glass-painters in this *genre* have a miniature delicacy and a perfection of means beyond reproach But it must be realized that we have entered on a new art, with its own aesthetic, and we must beware of any confusions of judgment in this respect. The unfortunate truth is that in England (and elsewhere in Europe) it was the glass-painters who were guilty of confusion. Social custom never called upon them for a domestic art comparable with Swiss glass-painting, but nevertheless they attempted to apply the methods of the domestic glass-painters (but without their technical skill) to the quite different needs of ecclesiastical buildings. The result was generally ludicrous, and always inappropriate. The crowning example of this misalliance of two inconsistent arts is to be found in the window designed by Sir Joshua Reynolds for New College chapel, Oxford, which was actually carried out by a china-painter.

The art of glass-painting in England during the 17th and 18th centuries does not offer sufficient material for any comparative criticism or positive judgment. We see nothing but scattered individuals, each expressing his own wayward fancy, displaying some ingenuity, supplying some passing need, but achieving nothing of significance.

Eighteenth and Nineteenth Centuries.—The Gothic revival that came as an offspring of the Romantic movement of the late 18th and early 19th centuries was not without its effect on the art of stained glass The styles and methods of the early Gothic period were reconstructed, but devoid of all inner reason or inspiring sentiment. The art thus reduced to sterile formulas was easily commercialized, and factories for the manufacture of windows, any size, any subject and colours to taste, sprang up all over Europe, but especially in Germany. From this state of things the Pre-Raphaelites and William Morris (*qq.v.*), largely inspired by Ruskin, revolted, and whatever faults we may impute to them, we must nevertheless acknowledge that they made a feeling for design once again a vital force in the social life of England—and, indeed, eventually of Europe We cannot enter here into the general character of Morris's achievements, but the basic fact upon which all his ideals rested was an intense aesthetic appreciation of mediaeval art As much, perhaps, can be said of the initiators of the Gothic revival, though we may suspect that as an aspect of romanticism their enthusiasm sprang from a sense of the remoteness, the strangeness, and the mysterious gloom of this earlier art rather than from any real understanding of its rational basis or religious significance. But Morris had a more logical appreciation of the Gothic, and his attitude was as free from insincerity as it was devoid of any desire to imitate. He realized that without the spirit, the form could not exist, and his real greatness and overwhelming importance in the history of modern craftsmanship springs entirely from the fact that he attempted to evolve a style and invent a technique appropriate to the expressions of his age. Burne-Jones designed his first cartoons for stained glass as early as 1857, and the St. Frideswide window in Christ church, Oxford, dates from 1859. These early
windows were carried out by Messrs Powell of the Whitefri
Glasshouse, but from 1861 Burne-Jones worked exclusively
Morris. Stained glass was included in the first exhibition

perhaps the finest of all (1887), and (perhaps the most important in London) the windows at Holy Trinity, Sloane street. What is reputed to be one of the finest examples of their work (1882) is a window at Biarritz in France, representing the marriage at Cana In addition to all the work designed for churches, and confined in the main to Biblical subjects, Burne-Jones and Morris made a good deal of stained glass for domestic or secular purposes. In their choice of subjects for this profane glass, they perhaps unduly confined themselves to the romantic and literary

8. "Merchant in his Warehouse." An example of Flemish stained glass of about 1530

predilections of their circle; but here again we cannot criticize their stained glass without entering into a discussion of their whole point of view. It is perhaps sufficient to say that it lacked the immediacy and the reality which we are entitled to expect from any contemporary expression of ideals.

The principles which William Morris established and followed give us an adequate criterion for the criticism of modern stained glass. It is sad to confess how little these principles have been followed in England itself. There is no longer any vital contact between the glass-painters and the significant artists of the day. And in all directions there is a relapse into a servile and lifeless imitation of mediaeval mannerisms, due to a natural disregard for those self-sacrificing ordinances which Morris observed. It seems that only the complete filling of every window in every old church will ever terminate this atrocious vandalism. There might be some satisfaction in the prospect if it were certain that that would put a stop to what is known in the trade as "period work"; but these *pastiches* of the art of other epochs find their way into practically every new church that is built, and the only hope of any reform would seem to lie in the final triumph of those principles for which William Morris stood. For these principles are not altogether dead; they have merely migrated, and on the Continent, especially in Germany, there is a school of glass-painting which is not only modern in intention, but is inspired by all that is vital and significant in modern art.

Like the stained glass of William Morris, this modern continental stained glass is both religious and secular. The work of Jan Thorn-Prikker and of Karl Schmidt-Rottluff has given to the symbols and images of Christianity a new intensity and realism for which there is no parallel this side of the Renaissance; and the abstract designs in which these glass-painters have experimented seem to open up infinite possibilities for this art of pure colour and light These artists work under the direction of Gottfried Heinersdorff for the Berlin firm of Puhl and Wagner In France, interesting experimental work is being done, for example, by MM. Mauméjean of Paris and Hendaye. Stained glass, which dominates all other arts in this matter of colour, would seem to be peculiarly fitted for those experiments in abstract design and harmony which have been distinctive of a certain phase of modern art. The difficulty in all contemporary glass-painting of a non-ecclesiastical kind, is not so much to extend the possibilities of the art in the direction of design and actuality, but rather to find a function for the art itself. For that we must look, with whatever faith we can summon, to those manifestations of civic and commercial enterprise for which our age is distinguished At Hagen, in Germany, the railway station has fine modern glass by Jan Thorn-Prikker; in Paris, the offices of a newspaper, *L'Intransigeant,* have windows with appropriate designs by Henri Navarre executed in leaded glass by Gaetan Jeannin. But these are isolated instances of what seems to be the only chance of a revival of the art commensurate with its possibilities There is nothing impossible in such a revival; the technical and material resources of the art are greater than they have ever been. All that is lacking is the desire; and to foster this we cannot do better than instil a wider consciousness of the unique and unrivalled beauties of the art as it has existed in the past. STAINES, a town in Middlesex, England. Pop. of urban district (1921) 7,326. A British village was situated at the Thames on the main road from London, and the crossing was one of the earliest bridged. A grant of oaks from Windsor forest for the repair of the bridge is recorded in 1262. The existing bridge, from the designs of George Rennie, was opened in 1831, after three bridges had failed in the previous forty years The name of Staines appears in the Domesday Survey, and is attributed to a stone marking an early limit of the City of London.

STAINLESS STEEL is a term used in a broad sense, particularly in America, to cover all "rustless steels" (*q v.*) or iron alloys designed to resist atmospheric corrosion, attack by organic solutions, hot or cold acids or chemicals, or scaling at elevated temperatures. In the restricted sense the term applies as a trade name to cutlery steels containing not more than 0·70% carbon and from 9 to 16% of chromium patented in 1916 by the English metallurgist Brearley. Chromium is the principal alloying element in most stainless metals (in the broad sense used above). Stainless or rustless iron contains less than 0 10% carbon and usually from 12 to 18% chromium, the balance being iron. It is inherently stainless to atmospheric corrosion, resists most acids and chemicals fairly well, and can be fabricated and worked cold like mild steel. Most of the possible iron-carbon-chromium compounds up to 3% carbon and 60% chromium have been patented, in addition to the Brearley patent noted above, and many of them containing more than 20% chromium, either in the form of forgings or castings, are non-scaling, *i.e*, will withstand oxidation at 1,100° C for weeks Such are very useful for furnace parts or pots to withstand flame. High chromium steels containing considerable nickel, for instance 17% chromium and 8% nickel, are non-rusting and are austenitic (*q.v*) in structure, very tough, may be hardened by cold work, and are being widely adopted by the chemical industry for processing equipment. Addition of silicon improves the resistance to scaling of this and plain chromium steels (gas engine valves, for instance, contain 8% chromium and 3% silicon). Other alloying elements are also used for special purposes. Superior resistance to hot or cold hydrochloric acid (until recently unobtainable by any but the noble metals) is given by an alloy of 20% iron, 20% molybdenum and 60% nickel. While the entire field of iron-carbon-chromium-nickel-silicon alloys is so big that the surface has barely been scratched, to say nothing of possible additions of tungsten, molybdenum, cobalt, copper, manganese, and aluminium, enough is known of the properties of various stainless alloys so that small pieces or large equipment which will corrode or scale no faster than 0 02 in per year can now be furnished for nearly all commercial liquids or industrial atmospheres. (E E. T.)

STAIR, JAMES DALRYMPLE, 1st VISCOUNT (1619–1695), Scottish lawyer and statesman, was born in May 1619, at Drummurchie in Ayrshire. After seven years as regent of the University of Glasgow he resigned, going to Edinburgh, where he was admitted to the bar on Feb 17, 1648 In 1649 he was appointed secretary to the unsuccessful commission sent to The Hague to treat with Charles II. by the parliament of Scotland, and was sent in the following year to Breda, where the failure of Montrose's expedition forced Charles to change his attitude and to return to Scotland as the covenanted king Stair met him on his landing in Aberdeenshire He refused in 1654 to take the oath of allegiance to the Commonwealth. Three years later (1657), Stair was appointed a commissioner of justice in Scotland, on the recommendation of Monk. After the Restoration he was received with favour by Charles, knighted, and made a judge in the court of session. He refused to take the declaration that the National Covenant and the Solemn League and Covenant were unlawful oaths, and, forestalling deposition, he resigned The king, however, summoned him to London, and allowed him to take the declaration under an implied reservation. In 1669 a family calam-

OLD WORLD STAIRCASES

1. The Scala Regia in the Vatican palace, designed by Bernini and built between 1663–66. Skillful use of exaggerated perspective by the progressive shortening of the columns makes it one of the most impressive of all monumental staircases. 2. The main staircase of the Bavarian State library, designed by Friedrich von Gaertner in the middle of the 19th century, has extreme simplicity as its key note. The contrast of plain wall and colonnade above gives an effective touch. 3. The gorgeous staircase of the Paris Opera, by Charles Garnier, 1861–74. 4. The spiral stairs leading to the jube or choir loft, in the church of St. Etienne du Mont, at Paris, 1600–05, by Biard, reveal the rich and delicate charm so characteristic of the French early Renaissance. 5. The terrace stairs of the temple of Confucius at Peking have the characteristic Chinese marble balustrades and in the centre a flat ramp, lavishly carved with dragon shapes, to form a spirit way by which beneficent spirits could enter. 6. One of the picturesque and simple stairs in the famous gardens of the Villa d'Este connecting the many levels. 7. The horseshoe staircase in the palace at Fontainebleau, 1634, by J. du Cerceau, noteworthy for the daring Baroque curves of its plan and famous as the place where Napoleon took leave of his troops before going to Elba. 8. The staircase, of flamboyant Gothic, built in the transept of Rouen cathedral, 1477–79, to allow direct entrance to the chapter library

RENAISSANCE AND MODERN STAIRCASES

1. Staircase by John Russell Pope in the Sloane house in New York, a characteristic modern interpretation of late Georgian delicacy and detail
2. The staircase of the third quarter of the 18th century, in the Moffatt-Yard-Ladd house in Portsmouth, N.H., characterized by the panels, bracketed ends and lavishly turned balusters, so typical of the developed American colonial
3. The famous stairs of the Petit Trianon at Versailles, though built by Gabriel in 1766 under Louis XV., show a simple delicacy and a use of straight lines characteristic of the style known as Louis XVI.
4. Much more typical of Louis XV. work is the lavish and monumental stairs of the Hôtel de Ville at Nancy, France, designed by E. Here, with iron work by Lamour
5. Modern freedom in design, the effort to combine many materials and to contrast straight and curved lines, characterize a stair designed by Patou in a Paris shop (La petite Jeannette)
6. The circular, concrete staircase in the Martel house in Paris, designed by R. Mallet-Stevens, an austere simplification of the more extreme types of modernism
7. In his Paris house, the same architect, Mallet-Stevens, combines concrete stairs with a railing of aluminium whose narrow aluminium supports, set at varying angles, catch varying reflections

Greece and Rome.—In classical Greece, interior staircases were common but unimportant; they were placed in out of the way corners, and often built of wood. In Rome, a new treatments for staircases became necessary. Many of the apartment houses indicated on the marble plan of Rome (*c.* A.D. 205), now in the Palazzo dei Conservatori at Rome, seem to have had stair towers built in the centre of a courtyard. The Colosseum (*q.v.*) at Rome (completed A.D. 80) has elaborate and practical entrance and exit stairs, by which the crowds could be readily handled. These, in general, are supported by sloping vaults and roofed by others. Similar staircases were common in the theatres.

Byzantine and Romanesque.—Merely inclined planes lead up within enormous buttresses at the ends of the narthex of S. Sophia (532) at Constantinople, so giving access to the galleries. In S. George at Salonica (late 5th century), a spiral staircase surrounds an open well. In the early Romanesque there is a growing use of the spiral staircase. To this development the great thickness of Romanesque walls and buttresses was particularly congenial, as it allowed the staircases to be built in solid masonry. Not only was the open circular well used, but the solid newel, in which each step had cut upon it a cylindrical form to act as part of the newel. This type of spiral staircase is still in use.

Gothic.—The Gothic spiral staircase was cut with the utmost cleverness. We have the radial stone cut in two levels, so that the ascent was twice as fast as by the ordinary method, thus allowing the radius to be remarkably decreased. Such circular staircases as lead up in the traceried turrets of the spire of Strasbourg cathedral in Alsace (1435) are miracles of daring design and delicate execution. The late Gothic period also produced a great number of beautiful interior staircases, like the "Stair of the Library" in Rouen cathedral (1477–79), which show that the possibilities of the staircase with straight runs were at last being realized. Of rich interior spiral staircases, the early 16th century staircase leading to the organ in S. Maclou, in Rouen, and the contemporary staircase to the jube (*q.v.*), or rood loft, of S. Étienne du Mont in Paris (in which a certain amount of Renaissance feeling is present) are noteworthy. In the larger houses the lack of communicating passages led to many staircases. Thus in the house of Jacques Coeur at Bourges (*c.* 1450), there are eight separate spiral staircases, whose exterior treatment, in rich, traceried towers, furnishes a great deal of the picturesqueness and varied beauty of such a building.

Renaissance.—During the Renaissance, despite such *tours de force* as Vignola's spiral stair in the palace at Caprarola (*c.* 1550), the general practice was to have important staircases run up in a straight flight, sometimes varied by landings, and sometimes with changes in direction between walls often crowned with a slanting vault. The most perfect developments of this type were made chiefly during the Baroque period. The magnificence of the huge interior flights of the Genoese palaces (*e.g.*, the "University," 1623, by Bianco) is famous. The Scala Regia is particularly remarkable in the artificial exaggeration of its perspective, through the gradual diminution of width and height as the steps ascend. In France the spiral staircase added by Francis I. to the château at Blois (1515–24) and the double circular staircase of the château of Chambord (begun 1519) are remarkable. The early Renaissance, however, produced its most remarkable results in the richly ornamented wooden staircases of Tudor and Jacobean houses. The usual arrangement was to have the staircase divided into comparatively short flights, at right angles to each other, around a central open well; the heavy newels at the corners were finished with urn-like finials at the top and carved drops at the bottom, the railing consisted of a large rail supported either by miniature arcades or square balusters, whose mouldings were often sloped to follow the stairs, and the whole was covered with intricate surface ornament of strap work. The staircase at Hatfield house (1611) is typical. The early Renaissance staircases of Spanish palaces are in most cases placed in one corner of the courtyard and run up between walls to a landing with a return flight that opens out onto the upper floor gallery. The walls, and sometimes even the treads and rises, are often cased in brilliant faience tiles. Even in staircases of more Italian type, with balusters, the richness of wall surface remains, as in the staircase of the hospital of S. Cruz at Toledo (1504–14), by E. de Egas. The climax of Spanish Renaissance monumental stair design is reached in the "Escalera Dorada" at Burgos cathedral (1519), by D. de Siloe, with its exquisite metal railing.

The developed classicism combined with the Baroque of the later 16th century to give a new trend to staircase design throughout Europe. Thus in France a gorgeous series of staircases was produced, of which the "Escalier des Princes" of Versailles is typical. The reaction to the lightness and gaiety of the Louis XV. period (*see* LOUIS STYLES) led to the development of many gracious and inviting house staircases of the type known as self-supporting, full of sweeping curves and with railings frequently of metal. In the Louis XVI. period the new, popular classicism restrained the exuberance of the earlier staircases but retained their graciousness and lightness; of these, one of the loveliest is that of the Petit Trianon at Versailles (1766), by Gabriel, with a beautiful iron railing. Meanwhile, the classic trend had expressed itself in England by the substitution of open string for closed string stairs, that is with the balusters coming down to the top of each tread, rather than being supported on a slanting member, or string, which received the ends of the treads. This at once made for a more interesting treatment at the ends of the steps, and led, eventually, to the development of the bracketed step end, in which scrolls and leafage of great richness were carved under the end of each riser. Moreover, the fact that English stairs were largely of wood inspired the design of turned balusters and newels of great variety. During the last half of the 18th century, a growing trend toward lightness and delicacy of design led to the substitution of plain, tapered shafts in place of elaborate balusters, and the use of stairs rising in continuing curves instead of straight flights and landings. The same development took place during the 18th century in the colonial work of North America. Thus certain of the earliest houses, like the Capen house at Topsfield, Mass. (1683), have closed strings and heavy newels of Jacobean type, while the Lee mansion at Marblehead, Mass. (1768), has a magnificent open string staircase, whose steps have panelled and scrolled ends, and whose twisted balusters are as rich as any contemporary work in England. The curved staircase of the Valentine museum at Richmond, Va. (1812), is typical of the later delicacy.

Modern.—During the middle and the third quarter of the 19th century, staircase design reached its lowest ebb, not only in England and France, but throughout Europe, except in the case of those monumental and official buildings on the Continent whose design never fell a victim to the current taste. Closed strings again became the fashion and balusters and newels of gargantuan proportions and bulbous and meaningless elaboration. Yet one of the most gorgeous and effective staircases in the world dates from this period, that of the Paris Opéra (1861–74), by Charles Garnier.

Two elements have vastly affected modern staircase design, steel and reinforced concrete. The use of steel has led to simple plans of straight runs and railings delicate and straightforward in design, with newels usually accented, as in the Jacobean wooden stairs. Reinforced concrete, on the other hand, is a material so flexible that the most daring curves and fantastic sweeps become structurally sound. Probably the most brilliant example of this modern type of staircase design is in the new portion of the Galeries Lafayette at Paris (1926), by F. Chanat, a conception of dizzying lightness, with modernist iron railings.

STRUCTURAL DESIGN

Stone and Marble Staircases.—Modern stone and marble staircases are of two main types. In the first the actual exposed treads and rises form, themselves, the structural elements. In the other type the treads and rises are supported upon a separate structural base which may consist of a masonry vault, a steel framework or a reinforced concrete slab. In the first class, in which the steps themselves are structural, the staircase is usually built into a wall at one side. Each step rests for a small distance upon the step below and is built into the wall for a distance sufficient to make the weight of the wall above prevent it from turning.

The undersides of the steps, where exposed, are frequently cut to form an inclined surface, following the slope of the stairs, and may be decorated with panelling or carved or other ornament. This type of stair can be used both for straight and curved runs, and is particularly applicable to monumental entrance halls, where the stair, in a triple run with two landings, or in a continuous, curved sweep, fills a recess opposite the door. In such staircases the railing is usually of metal with the uprights securely dowelled into the ends of the steps. Stairs somewhat similar can be built with the ends of the steps built into the walls on both sides, where a monumental run rises between two walls

Wooden Staircases.—These can be divided into two classes, closed and open string stairs. In both the essential support is given by rough timbers called carriages, which follow the slope of the stairs and are cut roughly to the shape of the under side of the steps. In the case of closed string staircases both sides of the staircase are finished by a sloping, straight-sided plank, approximately an inch and a half thick, on the inner faces of which grooves are cut, whose upper and outer faces exactly fit the top and side of the tread and riser; the under and inner sides are, however, sloped, so that wedges may be driven in to force the tread and riser boards into position and hold them with perfect rigidity. Similar wedges are driven in between the rough carriages and the under sides of treads and risers. To give additional strength, the treads and risers are, themselves, rebated together, so that a small, projecting strip of the tread fits into a groove in the bottom of the riser, and a similar strip on the top of the riser fits into a groove on the bottom of the tread The projecting portion of the tread is moulded and an additional small cover mould placed below to cover the joint.

In the open string staircase the strings at the end are cut to the shape of the steps, and the vertical cuts are usually mitred at 45°, so that the ends of the risers, also mitred, may form with them an invisible joint. In the ends of the treads dove-tailed sockets are left to receive the dove-tailed ends of the balusters; a moulding, exactly similar to the nosing, is then applied across the end of the step, and covers the bottom of the balusters. At times, bracketed and carved pieces are mitred at the ends of the risers and applied over the face of the string. It is this type of staircase that was the rule during the Georgian period in England and in the developed American colonial and early republic work. Where an open string stair is built against a wall, it is usually finished at the wall end by a closed or housed string, similar to that described, forming a base-board for the wall.

The structural strength for a wooden staircase is usually furnished by framing a heavy member, called a header, at the top and bottom of every run; to these headers the rough carriages are spiked, and the newels, if they exist, firmly fastened. The newels themselves are designed to receive the finished stair strings, and also the finished string member that is occasionally used at the edges of a floor in the stair-well opening. In staircases similar to those of the early 19th century in England and America, in which newels did not exist, except at the bottom, and in which stair rails and balusters were of the most extreme attenuation, and the whole frequently laid out with complex curves, strength was achieved by the most exquisite workmanship, whereby the careful framing of every part made the finished staircase an independently rigid structure. Frequently the curved plan itself furnished a certain amount of lateral rigidity. In modern staircases of this type additional strength is obtained by inserting iron or steel bands into the hand-rail; occasional balusters may be of steel, well fastened to the string.

Steel Staircases.—These have become almost universal in modern fireproof buildings of all types, except where unusual monumental effect is desired, and the design of steel staircases is largely standardized. They consist of a steel string on each side, which takes the form of a plate or channel of sufficient rigidity to carry the weight.

Iron spiral staircases are usually formed of cast iron members, each of which forms a tread and riser, and has at its inner end, a collar arranged to slip over a vertical pipe or cylindrical bar forming the central newel. Such spiral staircases are rigid independently of any wall, and are frequently used in open spaces, such as those existing in power houses, gymnasiums and the like. Reinforced concrete, sometimes finished as artificial stone, is used for stairs and permits of infinite variety of form.

Moving Staircases.—In many places where continuous transit between floors is necessary, as in large shops, underground railway stations and the like, moving stairs, sometimes known as escalators, are much used. These are of two types. In one, an endless belt carries on its surface links or blocks of sufficient roughness to act as treads. This endless band, at top and bottom, rotates around wheels or pulleys, motor-driven. At the bend the band disappears through the floor into a slot armed with steel arms, so designed as to occur one in each groove between the raised portions of the treads. Another continuous band on each side, geared to the same speed, serves as a hand-rail. The other type has a similar mechanical basis, but the belt, instead of carrying directly upon its upper surface blocks to form the treads, is designed to motivate actual continuous horizontal treads with risers radially shaped, so that at top and bottom the treads slide up on the risers into a continuous moving plane. Moving handrails are furnished as in the other type, and in addition, a moving band angularly across the top and bottom, to remove automatically any dropped objects. Moving stairs of the second type are always entered and left at the side, those of the other type directly at top and bottom.

Legal Regulation.—As stairs form one of the most necessary methods of exit from a building, their design has formed one of the most important portions of the building legislation of modern municipalities, especially in the case of public, commercial, industrial and educational buildings. Although there is much variation in the detailed requirements of different cities, the methods of regulation are almost the same and state: (1) where fireproof stairs are required; (2) the number of staircases; (3) size; (4) design. Thus, in addition to the universal requirements for structural solidity, the attempt is generally made to furnish at least two stair exits to any large, enclosed, upper floor area; and where fire risk and the danger of panic are unusually great, as in the case of theatres, to demand sufficient stairs to allow the building to be emptied in a very short time, without disorder. Widths of stairs are frequently determined in accordance with the number of people using them. In New York, for instance, each staircase must be designed to contain all the people of the floor area it serves, on the basis of one person to each 21 in. of width and each one and one half treads. Design is controlled by specifying the relationships of tread and riser, the distance apart and size of landings, whether or not curved stairs are allowed, etc., and often, because of the smoke danger, requiring exit stairs to be enclosed in a fireproof tower, with fireproof, self-closing doors at all entrances.

STALACTITES are pendent masses formed where water containing mineral solutions drops very slowly from an elevation. (Gr. σταλακτός, from σταλάσσειν, to drip.) They are seen, for example, beneath bridges, arches and old buildings where water percolating through the joints of the masonry has dissolved very small quantities of the lime present in the cement and mortar between the stones. On exposure to the air part of the water evaporates and the solution of calcium carbonate becomes supersaturated; a deposit of this substance ensues and as the drop continues to fall from the same spot a small column of white calcite very slowly grows downwards in a vertical direction from the roof. In the same way stalactites of ice (icicles) are produced in frosty weather as the water dropping from eaves of buildings, elevations, branches of trees, etc., very gradually, freezes. Other minerals often occur in stalactitic growths; thus we find in mines and in the cavities of mineral veins stalactites of limonite, opal, chalcedony and gibbsite. These are never of great size,

usually not more than 2 or 3in. in length, and probably the method of origin is exactly the same as that of the larger and more common stalactites of ice and calcite.

The conditions essential to the perfect development of stalactites appear to be (1) a very slow trickle of water from a fissure; (2) regular evaporation; (3) absence of disturbance, such as currents of air. Hence, ice stalactites form most readily on calm cold nights, and stalactites of ice or calcite are seen in greatest perfection in the interior of caves.

In limestone caves stalactites form in abundance as glimmering white columns covered with a thin film of water. The great caves, such as those of Adelsberg (in Styria), Jenolan (Australia), the Mammoth Cave (Kentucky), the Causses district in France, and the grottoes of Belgium, are divided into chambers which are richly festooned with stalactites, and fanciful names are given to various groups according to their similarity to different objects, natural or artificial. Ice caves of considerable size occur in the Arctic and Antarctic regions, and are draped with ice stalactites often wonderfully like those of limestone caves.

Where the water drops upon the floor of one of these caves evaporation still goes on and if the air be perfectly still the drop will always land on the same place and a pillar of deposit, called a stalagmite, will rise vertically, till in course of time it meets and joins with the stalactite above. As the stalactites thicken, they assume tapering forms with irregular surfaces. Large stalactites may be 3 or 4ft. thick, but in that case they are usually due to coalescence of adjacent ones. Single stalactites 2ft. in diameter are not rare. From data obtained by measurement of the rate of growth at the present day it has been estimated that as much as 200,000 years may have elapsed since certain thick stalactites began to grow. Caves are of great antiquity but there is, of course, no certainty that the conditions have remained uniform. Sir Archibald Geikie records that stalactites 1½in. in diameter had formed beneath a bridge in Edinburgh which was 100 years old; in caves, however, the rate of formation is rarely so great as this. Inscriptions on stalactites in the Adelsberg cave after 30 years had been covered with a scarcely perceptible film of new deposit. In one of the Moravian caves a stalactite, about as thick as a goose quill, was broken across in 1880, and in 1891 it had grown 3 or 4cm.; from careful observations it has been calculated that one of these stalactites, 7ft. long, may have been formed in 4,000 years. The stalagmitic crust on the floor of caves is usually mixed with blocks which have fallen from the roof, sand, mud and gravel carried in by floods, and the bones of animals and men which have inhabited the cave if it had an accessible entrance.

Stalactites also occur in the interior of the lava caves found in Hawaii, Samoa, etc. Often the upper surface of a lava flow has cooled to form a crust, while the interior is still perfectly fluid, and it sometimes happens that the liquid basalt has made its escape, leaving great cavities below the hollow roof of the lava. The interior of these caves is covered with a black shining film of glassy basalt, and black stalactites of lava hang downwards. Their surface is sometimes changed to brown or red by the action of the acid vapours which filled the cave after the lava retired. These stalactites are tubular, with bluntly rounded ends, and probably their mode of growth is somewhat analogous to that of icicles.

STALACTITE WORK, in architecture, one of the most general characteristics of all of the Mohammedan styles, consisting of a series of little niches, bracketed out one above the other, or of projecting prismatic forms in rows and tiers, connected at their upper ends by miniature arches. Its infinite varieties may be classified into three groups, the first consisting of those basically niche-shaped, in which the concave curve is the most important feature; the second group includes those in which the vertical edges between the niches are the most important feature, being set at all sorts of angles and having generally prismatic forms; the last group consists of elaborately intersecting, miniature arches. The first two groups occur commonly in Syrian, Moorish and Turkish work and in their simpler forms, in Persia; the last group is typically Persian and is found also in Mogul work in India.

Stalactites are of comparatively late development in Muslim art, the earliest buildings in Syria, Egypt and north Africa showing no traces of them. They seem to appear suddenly all over the Muslim world toward the beginning of the 12th century. Thus simple forms are found in the mosque at Ani in Armenia. built between 1072–1110, and they are common in Algiers and Sicily during the course of the century, as in the gate at Chella (1118–84), and in the building known as La Ziza at Palermo (1154). In Egypt the stalactite appears in panels flanking the main entrance of the El Akmar mosque at Cairo (1125–50). They reached their highest development in the 14th and 15th centuries, becoming the normal decoration for the heads of door niches and the bracketing under cornices and minaret galleries. The richest examples of the prismatic type are to be found in Moorish work in Spain, especially in the intricate wood and plaster ornament of such palaces as the 14th and 15th century Alhambra in Granada and the 14th century Alcazar at Seville. In Turkey, a peculiar type of faceted crystal shape is found and the form became the most common capital decoration.

STALIN, JOSEPH VISSARIONOVITCH (DJUGASHVILLI), general-secretary of the Russian Communist Party, was born in 1879, son of a Georgian peasant shoemaker. Young Joseph secured an education through being selected for a course at a Russian religious seminary. However, he was expelled for "unreliability." At 17 he joined a Social Democratic group and agitated among the workers of Georgia.

For organising demonstrations in Batoum in 1902 he was imprisoned, and in 1903 was exiled to Eastern Siberia for three years. In Jan. 1904 he escaped and returned to his political activities, frequently changing his pseudonym. He evaded arrest until 1908, when he was again exiled to Vologda province for three years. He escaped once more in 1909, returning to Baku and renewing his activities, but was speedily arrested and sent to Solvichegodsk for six years. Inside a year he escaped to St. Petersburg, but was arrested a third time after a few months and sent back to Vologda province for a further three years. He escaped in Dec. 1911, was again exiled in April 1912, but was once more in St. Petersburg (Leningrad) in September.

In March 1913 he was arrested and exiled to Turukhansk in Northern Siberia, where he remained until Feb. 1917. He was responsible for the Bolshevik campaign for the State Duma in 1913, directing the Bolshevik group in that Duma from outside, and in 1912–13 acting as one of the editors of the Bolshevik journals "Sviezda" (Star) and "Pravda" (Truth). He belonged to the central committee, and in the Soviet Government he became commissar for nationalities. Stalin fought against Yudenitch, Denikin and the Polish army, in 1919 and 1920 he was commissar for workers' and peasants' inspection, and from 1920 to 1923 was a member of the revolutionary military council. As general secretary of the central committee of the Russian Communist party, after Lenin's death he became the most powerful figure in the U.S.S.R., and held his position when his policy was assailed by other Communist leaders, securing the exile of Trotzky and other opponents.

His *Leninism* was translated (1928) into English.

STALIN, a town in the Ukrainian S.S.R. Pop. (1926) 105,739. In 1870 a British subject named Hughes received a concession from the Russian government to manufacture iron rails. His company started operations on the site of the present Stalin, formerly known as Hughesovka (Yuzovka). British, French and Belgian capital was freely invested in the development of the industry from 1880 up to 1914. The close conjunction of the Donetz coalfield to iron and manganese deposits made the industry very profitable. Following the 1917 revolution the industry was depressed, but from 1924 onwards progress has been rapid and the population of Stalin was doubled between 1923–6.

STALINGRAD, a province of Russia, lying on both banks of the lower Volga. Area 85,167 sq. kilometres. Pop. (1926) 1,406,927. It is a low-lying area, and the banks of the Volga for some distance on either side of the river are below sea-level. The soils on the left bank of the Volga river are salt steppe; on the right, as far as the Don river, they are light brown and

grey steppe, with salt efflorescences, while west of the Don is a fertile black-earth region. The climate is continental and the rainfall scanty and variable from year to year. The province lies in an area subject to terrible recurrent famines due to failure of rainfall, and rapid desiccation has been in progress for some time. In years of sufficient rainfall, the harvest is fairly good. The chief crops are summer wheat and winter rye; millet, sunflower seed, barley, oats and potatoes are grown in less quantity and vineyards are profitable in the south Maize cultivation is steadily increasing. Irrigation is the only hope for the district Experimental stations are working at Stalingrad and at Tingutin.

The most favourable region is the alluvial strip near the Volga and Akhtuba rivers, which is particularly wide near the town of Stalingrad. Here the temperature remains above freezing point for nine months in the year and the combination of alluvial soil, warmth and moisture makes grain, fruit and vegetable growing very profitable. Poplar trees attain a remarkable growth in ten years, and fruit trees bear for five years in succession. The nearness of the oil wells facilitates the use of internal combustion motors for irrigation purposes, and cheap and convenient routes for export are available The drawback is the frequent change in direction of the main watercourses and their connecting channels, which may convert a fertile garden into a waste of river mud, or even wash it entirely away. Dikes are being built to lessen this danger. Sheep, cattle, pigs and horses are bred, and in 1926 had made rapid progress towards restoration to pre-War level. The 1921 famine, particularly disastrous in this region, following on the civil war centring round the town of Stalingrad, had reduced their numbers catastrophically. There is also some camel breeding in the district Stalingrad is becoming a centre for timber but apart from Stalingrad (*q.v.*) there are no industrial areas in the province. The chief peasant occupations supplementing agriculture are fishing, flour-milling, oil-pressing, tanning, leather, fur-dressing, textiles and felt making and the making of pottery and household and farm implements. Lake Elton, one of the most productive sources of salt in Russia, is situated in the trans-Volga part of the province, but has no rail connection. The Don approaches the Volga very closely near Stalingrad, and the Soviet Government in 1928 embarked on a scheme to construct a canal linking the two rivers. The canal should be open for navigation by 1935.

The region was occupied in the 5th century by the Finno-Turkic Bulgars, who were in the 10th century driven northward by the Khazars, a closely related tribe. Later the region formed a part of the empire of the Tatar Golden Horde, one section of which was incorporated in the khanate of Astrakhan. The Russians in 1557 conquered Astrakhan and in 1589 erected the fort of Tsaritsyn on the site of the present town of Stalingrad, but the real absorption of the region into Russia involved a century of struggle with the nomads of the Volga during which there were perpetual Nogai, Kalmuck and Kirghiz raids on the Russian settlements. In the reign of Catherine II, the Russian peasants, the Cossacks and the dissatisfied native tribes rebelled under the leadership of Pugachev (1773–75) and fighting was fierce in the region between Kazan and Stalingrad. After the 1917 revolution, there was much disorder in the region, and considerable opposition to the Bolshevists, which was, however, finally overcome.

STALINGRAD (formerly Tsaritsyn), a town of Russia, the administrative centre of the province. Its position at the point where the Volga most nearly approaches the Don gave it great importance as a transhipment centre and after the construction of the railway links with the Don at Kalach and with the railway systems of Moscow and Leningrad, its growth was rapid. The town manufactures metal goods and machinery, has a naphtha-refining factory, 20 sawmills, a chemical factory, a brewery, a confectionery industry and mineral oil works. A tractor factory with an output of 10,000 tractors per annum was under construction in 1928 There are municipal electricity, water, tram and bus services. Pop. (1926) 143,243; (1897) 55,186.

A fort was erected here in 1589, after the fall of Astrakhan, to prevent the raiding of settlers by Kalmucks, Kirghiz and Circassians, often joined by Cossacks and runaway serfs The town took part in the rising in favour of the false Demetrius, and was captured by Stenka Razin in 1670. In 1773–75 it took a part in the rebellion of Pugachev. After the revolution of 1917, Stalin held the town and it was renamed in his honour.

STALL, literally a place where one may stand, and so applied to a separate division in a stable, shed, etc., in which a single horse, cow or other domestic animal may be kept, to a separate booth, bench or table in a market or other building, or in the street, on which goods are exposed for sale and in England to the higher-priced seats on the ground floor of a theatre. In cathedrals, monastic churches and the larger parish churches the stalls are fixed seats enclosed at the back and separated at the sides by high projecting arms, and placed in one or more rows on the north and south sides of the choir or chancel In a cathedral the canons and prebendaries have each a stall assigned to them In the chapels of the various knightly orders the stalls are assigned to the members of the order, thus, in St. George's Chapel, Windsor, are the stalls of the Knights of the Garter, in Henry VII.'s chapel in Westminster abbey are those of the Knights of the Bath, adorned with the stall plates emblazoned with the arms of the knight occupying the stall, above which is suspended his banner.

Architecturally considered, the stalls of a cathedral or church are a marked feature of the interior adornment They are richly carved, and are frequently surmounted by canopies of tabernacle work. The seats generally can be folded back so as to allow the occupant to stand upright or kneel, beneath the seat, especially in monastic churches, is fixed a small bracket, a *miserere* (*q v.*), which affords a slight rest for the person while standing. Among beautiful specimens of carved stalls may be mentioned the Early Decorated stalls in Winchester cathedral (1296); the Early Perpendicular ones in Lincoln minster (*c.* 1370); the early 15th-century canopies in Norwich cathedral (15th century), and the towering corner-stalls with their ornate carving filled with figures, in Amiens cathedral (1508–20).

STALLBAUM, JOHANN GOTTFRIED (1793–1861). German classical scholar, was born at Zaasch, near Delitzsch in Saxony on Sept. 25, 1793, and died at Leipzig, where he was rector of the Thomasschule, on Jan. 24, 1861. His reputation rests upon his work on Plato, of which he published two complete editions

See C. H Lipsius in the *Osterprogramm of the Thomasschule* (1861); R. Hoche in *Allgemeine deutsche Biographie*, vol xxxv.

STALYBRIDGE, municipal borough, Cheshire, England. It stands on the river Tame, in a hilly district. Pop. (1921), 25,216. The whole district is very densely populated. Stalybridge is one of the oldest cotton towns, the first cotton mill having been erected in 1776.

STAMBOLISKY, ALEXANDER (1879–1923), Bulgarian statesman, was born at Slavovitsa, in southern Bulgaria, Sept. 1, 1879, the son of a peasant landowner. After studying at the village school and later in the neighbouring town, he attended the agricultural college of Halle in Germany. On returning to Bulgaria, aged 18, he took up journalism, and in 1902 became editor of the organ of the newly-formed Agrarian League. Six years later he was elected to the Sobranye, where he led the Agrarian party.

He now began to organise the peasant masses, who form 80% of the total population of Bulgaria, into agricultural associations. In 1911, when the Grand Sobranye met at Trnovo to amend the Constitution, his first conflict with King Ferdinand occurred. After the treaty of Bucharest (1913) Stambolisky and the Agrarians were unmerciful in their criticisms of Ferdinand's policy, though deterred from extreme measures by the fear of external complications. Stambolisky's opposition to Ferdinand came to a head in 1915 during the negotiations that preceded Bulgaria's entry into the World War. Stambolisky strongly backed the Entente in spite of the King's anger, pressure from the Government and the growing influence of the Central Powers. Summoned before the King, Stambolisky threatened him with personal violence if he should fight against the Allies, reminding him that he had a crown to lose. Ferdinand ordered his arrest. He was tried by court-martial and condemned to penal servitude for life.

In Sept 1918, when the resistance of the Bulgarian troops

began to slacken, Ferdinand released Stambolisky, who left for the Macedonian front. He returned at the head of the insurrectionary troops and their arrival at Sofia resulted in Ferdinand's abdication and flight. A partisan of the new ruler, King Boris, Stambolisky became a member of the Cabinet in Jan. 1919 and Prime Minister in Oct.; as head of the Government he went to Paris and signed the Treaty of Neuilly in the same year. In Feb. 1920 he dissolved the Sobranye, and the following month was returned to power at the head of a homogeneous Agrarian majority. From 1920 to 1923, the Agrarians under Stambolisky ruled Bulgaria with a rod of iron. They had the Radoslavov Cabinet, which had brought Bulgaria into the World War, condemned to death by popular vote. Stambolisky also carried measures based on the interest of the peasants (*see* BULGARIA), and declared: "Sofia, that Sodom, that Gomorrah, may disappear. . . . I shall not weep for her." Through his influence post-War Bulgaria loyally carried out the terms of the Peace Treaty, won the esteem of the Allies, and secured a reduction of reparations. Stambolisky also made persistent efforts to improve Bulgaria's relations with Yugoslavia, with which country he concluded an agreement at Niš (1922). His ultimate ideal was probably some kind of federal South Slav State, embracing Bulgaria.

The overthrow of the Government by a military faction on June 9, 1923, was caused partly by dissatisfaction with Stambolisky's domestic policy and partly by the influence of the Macedonian party. The change of régime took place in one night, the Agrarian Ministers being arrested in their homes. Stambolisky, pursued by an armed detachment to his native village of Slavovitsa, escaped and fled across the mountains, hoping to reach the frontier. After being followed by soldiers for three days, he was eventually surrounded and shot on June 12. A formidable personality, attractive in many ways, and made of finer clay than the average Balkan statesman, Stambolisky has been called a modern Rienzi. Tall and broad, his demeanour was fierce and his movements ungainly; his rough-hewn face was crowned by a mass of black hair; he impressed everyone with his strength and the sincerity of his advocacy of a "Green International," to unite the peasants of all countries. Stambolisky published *Authority, Anarchy and Democracy;* and *What a Politician ought to be.*

STAMBOLOV, STEFAN (1854–1895), Bulgarian statesman, was born on Jan. 31, 1854, at Trnovo, the ancient Bulgarian capital, where his father kept a small inn. Under Turkish rule it was impossible to obtain a liberal education in Bulgaria, and young Stambolov, after attending the communal school in his native town, was apprenticed to a tailor. During the politico-religious agitation which preceded the establishment of the Bulgarian exarchate in 1870, a number of Bulgarian youths were sent to Russia to be educated at the expense of the Imperial government; among them was Stambolov, who was entered at the seminary of Odessa in order to prepare for the priesthood. He was expelled for his association with Nihilists, and, making his way to Rumania, he entered into close relations with the Bulgarian revolutionary committees at Bucharest, Giurgevo and Galatz. In 1875, though only twenty years of age, he led an insurrectionary movement at Nova Zagora in Bulgaria, and in the following year organized another rising at Orekhovitza. In the autumn of 1876 he took part as a volunteer in the Serbian campaign against Turkey, and subsequently joined the Bulgarian irregular contingent with the Russian army in the war of 1877–78. After the signature of the Berlin Treaty in 1878 Stambolov settled at Trnovo, where he set up as a lawyer, and was soon elected deputy for his native town in the Sobranye, of which he became president in 1884. The revolution of Philippopolis, which brought about the union of Bulgaria with eastern Rumelia, took place on Sept. 18, 1885, and it was largely owing to Stambolov's advice that Prince Alexander decided to identify himself with the movement. War with Serbia followed, and Stambolov served as an ordinary soldier in the Bulgarian army.

After the abduction of Prince Alexander (*q.v.*) (Aug. 21, 1886) Stambolov, who was then at Trnovo, established a loyal government at Trnovo, issued a manifesto to the nation, nominated his brother-in-law, General Mutkurov, commander-in-chief of the army, and invited the prince to return to Bulgaria. These measures resulted in the downfall of the provisional government set up by the Russophil party at Sofia. On the abdication of Prince Alexander (Sept. 8) Stambolov became head of a council of regency, with Mutkurov and Karavelov as his colleagues; the latter, however, soon made way for Jivkov, a friend and fellow townsman of the first regent. Stambolov frustrated the mission of General Kaulbars, whom the Tsar despatched as special commissioner to Bulgaria; suppressed a rising organized by Nabokov, a Russian officer, at Burgas; quelled military revolts at Silistria and Rustchuk; held elections for the Grand Sobranye, despite the interdict of Russia, and eventually secured the election of Prince Ferdinand of Coburg to the vacant throne (July 7, 1887). Under the newly-elected ruler he became prime minister and minister of the interior, and continued in office for nearly seven years.

The aim of his foreign policy was to obtain the recognition of Prince Ferdinand, and to win the support of the Triple Alliance and Great Britain against Russian interference in Bulgaria. He gained the confidence of the Sultan, and obtained concessions for the Bulgarian episcopate in Macedonia (*see* MACEDONIA). With the assistance of Austria-Hungary and Great Britain he negotiated large foreign loans which enabled him to develop the military strength of Bulgaria. He was still the despot. Major Panitza, after a conspiracy, was shot at Sofia in 1890; four political opponents were hanged at Sofia in the following year, and Karavelov was sentenced to five years' imprisonment.

His mood was emphasized by the assassination of his colleague, Beltchev, in 1891, and of Dr. Vlkovitch, the Bulgarian representative at Constantinople, in 1892, and eventually proved intolerable to Prince Ferdinand, who made him resign in May 1894.

He was now exposed to the vengeance of his enemies. On July 15, 1895, he was attacked and barbarously mutilated by a band of Macedonian assassins in the streets of Sofia, and succumbed to his injuries three days later. His funeral was interrupted by disgraceful riots, and an effort was made to perpetrate an outrage on his remains. No attempt was made to arrest his murderers; two persons, however, arraigned for the crime in 1896, were subjected to almost nominal penalties. (J. D. B.; X.)

STAMFORD, a town of Lincolnshire, partly in Northamptonshire. Pop. (1921) 9,882. It formerly possessed 14 parish churches, but now has only six. There are some remains of the 7th century Benedictine monastery of St. Leonard's and a west gate of the Carmelite monastery (1291). To the south of Stamford, in Northamptonshire, is Burghley house, the seat of the marquis of Exeter, a fine quadrangular mansion dating from 1587, containing a noteworthy art collection.

Apart from the tradition preserved by Henry of Huntingdon that the Saxons here defeated the Picts and Scots in 449, Stamford (*Staunford*) is a place of great antiquity. The Danes built a fort here on the north bank of the Welland, round which a town existed when in 922 King Edward fortified the opposite side of the stream. It passed again into Danish hands and was one of the five boroughs recaptured by Edmund Aetheling in 941. The priory of St. Leonard was a cell of Durham, and a charter of Edgar dated 972 mentions a market and a mint. In the reign of Edward the Confessor Stamford was a royal borough governed by 12 lawmen. The Norman castle, built before 1086, was thrice besieged by Henry II., but only yielded in 1153. Henry III. gave the town a charter in 1256.

Stamford was known for its monastic schools, and in 1333 was chosen as the headquarters of the students who seceded from Oxford, and an Early Decorated gateway remains of Brasenose Hall. The attempt to establish a regular university was prohibited by royal authority. The defeat of the Yorkists here was followed by the decay of the castle in the reign of Richard III., and the history of the place later centred round the family of Cecil.

See E. C. Mackenzie-Walcott, *Memorials of Stamford, past and present* (1867); J. Drakard, *The History of Stamford in the County of Lincoln, comprising its ancient progressive and modern state* (1822); C. Nevinson, *History of Stamford* (1879); *Victoria County History: Lincoln.*

STAMFORD, a city of Connecticut, U.S.A., on the Boston Post road. Pop. (1920), 35,096 (30% foreign-born white); 1928 local estimate, 44,000. The city lies around a broad bay (2 m.

across at the entrance and 1½ m. wide), from which two tidal inlets extend. The city still has the charm of a New England village. It is a residential suburb, with 90 trains daily to and from New York. It is also an important industrial centre. The town of Stamford (known for the first year by the Indian name of Rippowam) was settled in 1641 by 29 persons who seceded from the Wethersfield church and came under the New Haven jurisdiction. In 1662 it submitted to Connecticut. The borough was incorporated in 1830 and became a city in 1894.

STAMITZ, JOHANN WENZL ANTON (1717–1757), the eldest and most important of a family of Bohemian musicians famous in the 18th century. He was born at Deutschbrod on June 19, 1717. He was a solo violinist at the coronation of the emperor Charles VII. (1742), and in 1745 the elector took him to Mannheim as director of the chamber of music. Stamitz and his successors are known as the Mannheim school. Although Phillip Emanuel Bach in Berlin and the young school in Vienna were arriving at similar results, it seems certain that Stamitz was the real pioneer, who not only demonstrated the dramatic value of the "working-out" section of the first movement of a sonata or symphony, but, by incorporating the minuet, definitely established the four-movement form. In addition he demanded of the orchestra a greater independence from the different instruments, singling out the much neglected viola. He died at Mannheim on March 30, 1757. His works include 27 concertos, sonatas and solos for violin; several sets of symphonies, and harpsichord music. Johann's brother Anton Thaddaeus Stamitz (1721–1768) was a 'cellist at Mannheim.

Much confusion has arisen between Johann and his eldest son Carl Stamitz (1746–1801), who sometimes used the name Johann, while the father was frequently called Johann Carl or Carl Johann. He produced an opera, *Der verliebte Vormund,* at Frankfurt and another, *Dardanus,* in St. Petersburg. He died at Jena in 1801. His more elaborated 70 symphonies are chiefly written for larger orchestras than his father's.

An introduction with details of the family, by Hugo Riemann, is included, together with a thematic catalogue of 45 symphonies and 10 orchestral trios, in Series III. i. of *Denkmäler deutscher Tonkunst in Bayern,* and other compositions of Johann and Carl are found in Series VII. i, XV. and XVI. of the same work *See* also Grove, *Dictionary of Music and Musicians;* Riemann, *Lexikon;* Eitner, *Quellen-Lexikon;* R Sondheimer, *Die formale Entwicklung der vorklassischen Sinfonie* (*Allgem Musikztg.* Jan. 1922); P. Bekker, *Musikgeschichte* (1926) p. 126 *et seq.*

STAMMERING or Stuttering, a spasmodic affection of the organs of speech in which the articulation of words is suddenly checked and a pause ensues, often followed by a repetition in rapid sequence of the particular sound at which the stoppage occurred. There are many grades, from a slight inability to pronounce with ease certain letters or syllables, to a condition in which the muscles, not only of the tongue and throat and face, but even of those of respiration are involved in spasm.

In normal speech exquisite co-ordination of muscular movement is necessary in larynx, cheeks, tongue, lips, involving also complicated nervous actions. It is when the co-ordination is not effected with sufficient precision that stammering results. Stammering rarely shows itself before the age of four or five years, and often it develops in a child in a feeble state of health.

Stammerers, as a rule, find the explosive consonants *b, p, d, t, k* and hard *g* the most difficult to articulate, but many also are unable easily to deal with the more continuous consonants, such as *v, f, th, s, z, sh, m, n, y,* and in severe cases even the vowels may cause a certain amount of spasm. Usually the defect is not observed in whispering or singing

The condition named *aphthongia* totally prevents speech, and may, at intervals, come on when the person attempts to speak; it is only temporary, and is usually caused by nervous excitement.

Stuttering may, it seems, be overcome in some cases by instruction in reading and speaking slowly and deliberately, carefully pronouncing each syllable When feeling the tendency to stammer, the speaker should pause, and then by a strong voluntary effort attempt to pronounce the word. He should also be taught how to regulate respiration during speech, so that he may not fail from want of breath. In some cases aid may be obtained by raising the voice towards the close of the sentence. Sounds or combinations of sounds that present special difficulties should be carefully studied, and the defect may be largely overcome by a series of graduated exercises in reading. Intoning is often useful. Some maintain that benefit from such education is often merely temporary. In any case the psychical basis of stammering calls for the most pronounced attention in treatment. In very severe cases, where the seizures affect other muscles than those of articulation, medical treatment is necessary.

STAMP, SIR JOSIAH CHARLES (1880–), British economist, was born in London on June 21, 1880. Educated at the University of London, he entered the civil service (inland revenue department) in 1896, and became assistant secretary to the board in 1916. In 1919 he resigned from the service to join Nobel Industries Ltd, of which he was a director and secretary until he accepted the new post of president of the executive of the London, Midland and Scottish railway in 1925. Stamp sat on the royal commission on income tax (1919); on the finance arbitration committee for Northern Ireland (1923–24); on the committee on taxation and national debt (1924); on the Dawes Committee on German currency and finance (1924); on the court of enquiry into the coal industry (1925); and on the Paris committee of enquiry into the reparations question of 1929. He held many academic honours, and was created G B E. in 1914. He is the author of many books, e.g, *Wealth and Taxable Capacity* (1922, 2nd ed. 1923).

STAMP DUTY, a tax imposed in Great Britain on written documents which are evidence of legal rights involved.

The payment of the tax is denoted by a stamp which is impressed on or affixed to the document.

The Stamp Act of 1891 is still the principal act governing stamp duties But new duties and increases have been authorized by successive Finance Acts The revenue from the duty for the year ending March 31 amounted to £27,000,000.

In some cases, moreover, parties have no discretion to dispense with written evidence. For example, contracts for insurance (marine, life or general accident) must be expressed in the form of a stamped policy and failure to do this not only vitiates the contract but renders the parties liable to fines

The sanction of the act is expressed in very wide terms. Except in criminal proceedings, an instrument executed in Great Britain, or relating, wherever executed, to any matter or thing done or to be done in Great Britain, is not to be given in evidence or to be available for any purpose whatsoever, and it is the duty of all judicial officers before whom an instrument is tendered in evidence to take notice of the absence or insufficiency of duty. Further, any person whose duty it is to enrol or record an instrument liable to duty is liable to a fine if he enrols or records an instrument insufficiently stamped. On the other hand, the stamp does not add to or warrant its legality, it merely makes it possible for the legality to be examined

Classification of Duties.—Dutiable instruments may be classified broadly as follows.—

1. Instruments evidencing the creation of contractual rights—bills of exchange, bills of lading, charter parties, contracts of insurance, bonds and innominate contracts
2. Instruments evidencing the transfer of property (real or personal) or the creation of rights in property—conveyances of realty, assignments of personalty, mortgages, leases, transfers of stocks and shares and bearer securities.
3. Instruments evidencing the grant of privileges—grants of dignities and honours (patents of peerage, etc.), admissions to learned professions, licences to practise as solicitors, notaries, etc.

For the year ended March 31, 1927, the yield of duty under the principal heads of charge was as follows.—

	£
Conveyances of land and property other than stocks and shares at £1 per cent.	6,000,000
Transfers of stocks and shares at £1 per cent.	6,000,000
Companies' share capital duty at £1 per cent.	3,500,000
Cheques at 2d.	3,250,000
Receipts at 2d.	2,250,000
Marine Insurance Policies and Bills of Lading	600,000

STAMPINGS, DROP: *see* Pressed Metals.

STAMPS: *see* Post and Postal Service and Philately.

STANCIOFF, DIMITRI (1864-), Bulgarian diplomatist, was born at Sistov, Bulgaria, in May 1864, and studied at the Theresianum College, Vienna. In 1887 he entered the Foreign Office, Sofia, and was a member of the delegation entrusted with electing Ferdinand, in due course becoming head of the new King's political Cabinet. Afterwards he was successively Bulgarian representative at Bucharest, Vienna and St. Petersburg. He became Minister of Foreign Affairs in 1906 and was for a time Prime Minister after the murder of Petkoff. In 1908 he resigned and became Minister in Paris, where he remained until 1915 when he was sent to Rome. He was made a member of the Bulgarian Delegation to the Paris Peace Conference, and in 1920 was appointed Bulgaria's representative to the Court of St. James. Stancioff was Bulgaria's chief delegate to the first international Peace Conference in 1899 and was a permanent member of the International Court of Arbitration.

STANDARD. For the various meanings of this word *see* Weights and Measures; Physical Units, Units and Dimensions, Standards Department; Electricity and Time, Standard.

STANDARD, BATTLE OF THE, a name given to the battle of Aug. 22, 1138, near Northallerton, in which the Scottish army, largely composed of wild and undisciplined Highlanders and Galloway Picts under King David, was defeated by the English levies of Yorkshire and the north Midlands. The latter formed a single deep line of dismounted men in front of a chariot carrying the consecrated banners of St. Peter of York, St. John of Beverley, St. Wilfred of Ripon and St. Cuthbert of Durham. King David planned to use his nucleus of knights and archers to lead the way and open a gap in the English line, but the fierce pride of the clansmen compelled him to give them precedence. Their headlong onset was repulsed. Left isolated except for his bodyguard of knights, King David retired from the field.

See C. Oman, *Art of War in the Middle Ages*, vol. i. 390–396 (1924).

STANDARDIZATION, means setting up standards by which extent, quantity, quality, value, performance and service may be gauged. Instances are the mile, the hour, the pound, the bushel, and the dollar.

Many individual manufacturers have standardized their products to gain the advantages and economies of mass or volume production. Several of these manufacturers maintain standards departments in their organizations to supervise design and production with the view to effecting maximum interchangeability between parts entering into the finished product, by securing consistent uniformity in their size and other essential characteristics. The standards established by one company are sometimes, though not always, of interest to another company.

Standardization offers many advantages to manufacturers, distributors and consumers. "(1) Standardization stabilizes production and employment, since it makes it safe for the manufacturer to accumulate stock during periods of slack orders, which he cannot safely do with an unstandardized product. (2) It reduces selling cost. Possibilities of reduced costs are generally even greater in distribution than in production. (3) It enables buyer and seller to speak the same language and makes it possible to compel competitive sellers to do likewise. (4) In thus putting tenders on an easily comparable basis it promotes fairness in competition, both in domestic and in foreign trade. (5) It lowers unit costs to the public by making mass production possible, as has been so strikingly shown in the standardization of incandescent lamps and automobiles. (6) By simplifying the carrying of stocks, it makes deliveries quicker and prices lower. (7) It decreases litigation and other factors tending to disorganize industry, the burden of which ultimately falls upon the public. (8) It eliminates indecision both in production and utilization—a prolific cause of inefficiency and waste. (9) By concentrating on fewer lines, it enables more thought and energy to be put into designs, so that they will be more efficient and economical. (10) By bringing out the need of new facts in order to determine what is best and to secure agreement on moot questions, it acts as a powerful stimulus to research and development, and it is thus in decided contrast to crystallization resulting from fixity of mental attitude. (11) It is one of the principal means of getting the results of research and development into actual use in the industries. (12) It helps to eliminate practices which are merely the results of accident or tradition and which impede development. (13) By concentration on essentials and the consequent suppression of confusing elements intended merely for sales effect, it helps to base competition squarely upon efficiency in production and distribution and upon intrinsic merit of product. (14) Standardization is increasingly important for the maintenance and development of foreign trade. (15) The efficiency of competing countries, increasing through national standardization programmes, is likely to stiffen competition between those countries. (16) Joint effort in bringing about standardization within and between industries almost invariably leads to better understanding and to beneficial co-operation along other lines—a step toward the integration of industries" (*Mechanical Engineering*, Aug. 1926).

Practically every major American industry has co-operated with its allied or related industries in standardizing products or commodities of mutual interest. This group movement is one of the outstanding post-War developments in America.

The American Engineering Standards Committee.—In order to make standardization on a national scale possible, a clearing house or co-ordinating agency has been established to bring about systematic participation by, and co-operation of, the many organizations and associations individually working on the general problem. This agency is the American Engineering Standards committee, a federation of 33 national organizations, including nine major engineering societies, 18 national industrial associations and six departments of the Federal Government.

Government Co-operation in Standardization.—The United States Government is interested in industrial standardization in two ways: first, as a purchaser, in the specifications for materials and apparatus, and secondly, through its service and research bureaux, in innumerable standardization questions. Thirty-three branches of the United States Government are officially represented on sectional committees of the American Engineering Standards committee. The bureau of standards of the Department of Commerce is acting as sole or joint sponsor for 13 projects; the bureau of mines, Department of Commerce, for seven; the forest service, Department of Agriculture, for two; and the public health service, Treasury Department, for one. In addition, the bureau of standards, for example, is officially co-operating through representatives on sectional committees on 69 projects. One or more branches of the Federal Government is participating in this way in practically all the work of the American Engineering Standards committee. The Department of Labour designates representatives on all sectional committees dealing with safety codes, and is publishing approved codes as Government documents. The State Governments are actively participating in the work, chiefly through national organizations of State commissions, the most active being the International Association of Industrial Accident Boards and Commissions and the Association of governmental labour officials. The highway and traffic commissions (which co-operate through the American Association of State Highway Officials and the regional conferences of motor-traffic administrators) and the railway and utility commissions also participate in this work.

The bureau of standards of the Department of Commerce is a national agency for standardization and industrial research. Because they carry Government approval, the standards developed in the course of bureau research often tend to become those demanded by intelligent buyers throughout the country. For example the Government specifications for cement and the tests therewith have become the commercially accepted standard. Again, the Government buys about $1,000,000 worth of electric lamps annually on specifications. The acceptance is based on bureau of standards' tests, which have become the standard of the country.

The Federal specifications board was organized under the bureau of the budget in 1921. It is composed of representatives of each of the purchasing units of the U.S. Government, the chairman of the board being the director of the bureau of standards,

ex officio. Its purpose is to unify Government specifications and to bring them into line with the best commercial practice.

The Bureau of Standards at Washington has been reorganized to include commercial standards as well as research and testing. As to commercial standards, its service is mainly promotional in character It helps to work out such standards and adds periodical audits of adherence, also co-operating with the United States bureau of foreign and domestic commerce in applying the standards to foreign commerce.

The American Marine Standards committee was organized primarily to promote simplification of practice and economy in the construction, operation and maintenance of ships and ports facilities. The underlying authority is vested in a membership enrolled from the marine and allied industries. In 1928 its field was confined to three divisions: hull details, engineering (machinery) details, and ship operation details and supplies. Progress of similar work abroad is closely observed by exchange of publications with foreign bodies

Standardization for Design, Construction and Tests.—For the purpose of bringing to the user the best obtainable opinion on the merits of appliances, devices, machines and materials in respect to life, fire and collision hazards, and theft and accident prevention, the Underwriters' Laboratories (Inc.) was established and is maintained by the National Board of Fire Underwriters. The laboratories are conducted for service and not for profit.

One of the most widely circulated codes of the laboratories is its code for electrical appliances, which consists of standards for design and construction, and tests of devices and materials for use in electrical circuits for light, heat and power, and for the forms of supervision of such products marketed under inspection and listing by the Underwriters' Laboratories. The code is in looseleaf form to facilitate revisions. The following standards are included and may be also obtained as separate pamphlets: armoured cables and cords; cabinets and cut-out boxes, cartridge-enclosed fuses; cut-out bases; electric ranges; electric signs; fixture wires; flexible cords, flexible non-metallic tubing; ground clamps; heater cords; knife switches; panel board; renewable cartridge-enclosed switches; rigid conduits, rubber-covered wires and cables, snap switches; soldering lugs. Additional standards are constantly under consideration and in preparation. Lists of inspected electrical appliances which have been examined and tested and found to comply with the standards of the laboratories are published semi-annually.

Standardization in Building and Housing.—The work on building and housing seeks to promote a wider application of the best standards for building materials and design to the $6,000,000,000 or more of new construction carried out each year. In this way it helps to widen the practical usefulness of the laboratory and field research work of the bureau of standards and of other scientific bodies, and to secure a more general adherence to approved specifications and simplified practice programmes for elimination of excess dimensional varieties.

The advisory building code committee has been most active and influential in this field. More than $3,000,000,000 worth of construction work is carried out each year under the conditions prescribed by local building codes, and each of the committee's reports gives concise recommendations suitable for inclusion in such codes

Standardization of building codes took a prominent position in the public mind as a result of the activities of the United States Senate committee on reconstruction and production appointed in 1920. Salient facts brought out by this committee were that there was a wide diversity in building-code requirements; that this proceeded from unscientific methods in preparing codes, and that large savings appeared to be possible through more uniform requirements These were facts already well known to many architects and builders, but their significance was thrown into relief by the twin evils of inadequate housing and stagnant building.

Practical attack of the problem was commenced in 1921 through the appointment by Secretary Hoover of a committee of seven architects and engineers of high professional standing to undertake thorough and impartial studies. The country needed homes. The local code requirements for such construction appeared to be in a chaotic state. No careful investigation had been made up to this time. Accordingly a subcommittee on plumbing was appointed by Secretary Hoover and this outlined a series of tests to be carried out at the bureau. These tests were continued over a period of more than two years and the principles deduced from them were incorporated in the subcommittee's report, *Recommended Minimum Requirements for Plumbing in Dwellings and Similar Buildings,* published in 1924 The report contains a recommended code and a complete report of the experiments at the bureau of standards.

Purchasing and Standardizing Agencies.—General purchasing agencies have been established in a number of cities.

Among the municipalities, New York city has formulated and utilized the greatest number of purchase specifications, more than 1,600 specifications for 42 different classes of commodities having been prepared for this purpose. Practically all of the work of standardization is done in the department of purchase Recommendations for standards are forwarded to the board of estimate and apportionment, which consists of the mayor, the controller, the president of the board of aldermen, and the five borough presidents. Standards adopted by this board are compulsory on all city departments

In every one of the 48 States, standards for materials used in the construction and maintenance of roads and bridges have been established by the State highway commissioners Much of the activity in this line of standardization can be attributed to the aid given to the States by the Federal Government for the building of the main highways of the country

Pan-American Conference on Standardization.—The first Pan-American conference was held at Lima, Peru, from Dec 23, 1924, to Jan. 6, 1925. The general purpose of the Lima conference was to prepare the ground for co-operation in standardization between the republics of the Western Hemisphere and to facilitate international commerce through standardization work No attempt was made to undertake any technical work at the first meeting, but co-operative relations were established and means were provided for continuing study for future work. The conference was attended by representatives from 13 countries —Brazil, Costa Rica, Cuba, Guatemala, Haiti, Mexico, Nicaragua, Panama, Paraguay, Peru, United States, Uruguay and Venezuela. It was the general opinion that standardization can be used by the Latin Americans in three ways: first in expediting and making more efficient their own industrial development; secondly in improving the effectiveness of their buying in foreign countries; and thirdly in the development of better methods for producing and marketing their own raw products The formal resolutions of the conference, as an official body, recommended that there be a convention between the American States, providing for co-operation in standardization matters; the establishment in each country of one or more organizations dealing with standardization matters, either governmental or industrial or mixed, as each may deem best; the use for the present of the Inter-American High Commission as the channel of communication; and the gradual compilation of a technical vocabulary in Spanish, Portuguese, English and French.

The second Pan-American standardization conference was held at Washington, May 9 to 12, 1927. Seventeen of the American republics were represented at this meeting, the programme of which was confined to standards for use in the inter-American trade in coffee, cocoa, fruits, hides, certain oil-seeds and wool. The formal recommendations concerned the organization and development of the standardization work in the several countries; the establishment of appropriate agencies to fight plagues and pests affecting animal and vegetable production; the early acceptance of wool type sample standards; and the immediate development of uniform specifications for agricultural products and raw materials important in inter-American trade.

The following are among the recommendations in the report of the Hoover committee: Products should be standardized so far as is consistent with progressive development of manufacturing. Materials should be standardized to the fewest practicable kinds, sizes and grades. At least the details of equipment, including ma-

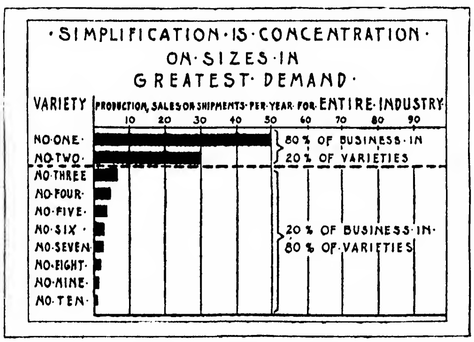
chines and tools, should be standardized so as to permit of the widest interchangeability and maximum usefulness consistent with improvements in design and invention. Performance standards should be developed as a valuable aid to planning and production control. Under the week-work system such standards are the basis of a just measurement of the individual worker's performance and of the adjustment of his wage rate to his capacity. Under the piece-rate system they are the basis of just rates. Without standardization of appliances, conditions, work content and method, no valid performance standard can be maintained. By constantly comparing actual performance with the standards and promptly investigating the causes of departure from standard, the manufacturer can quickly detect adverse conditions as they creep in, and can rectify them. (R. M. H.)

SIMPLIFIED PRACTICE OR SIMPLIFICATION

Another branch of standardization is the commercial elimination of unnecessary variety in sizes, dimensions, grades or qualities of common commodities. Its chief purpose is to reduce the economic waste resulting from the production and distribution of too many varieties of the same general class of goods. The wastes of over-diversification are unduly large inventories, increased cost to carry them, slower turnover, idle investment, heavy obsolescence and decreased profits. Advantages gained through simplification, by the manufacturer are decreased production costs and selling expenses, smaller inventories, faster turnover and consequently improved profits. Distributors likewise are enabled, through simplification, to reduce their inventories to the lines that sell well and thus to secure speedier turnover and better profits. Consumers benefit from simplification through lower prices, improvements in quality of product and in the service of supply.

Analyses of many different lines of products have shown to the U.S. department of commerce that usually 80% of the year's total business in any line of products is done in 20% of the varieties in which that line is offered. The remaining 80%, producing only 20% of the year's business, usually provides a fertile field for simplification.

During the World War, the United States organized its war industries board which, among other responsibilities, was charged with the restriction of production of non-essential goods, in order to divert to war purposes the material and labour represented in those goods. The conservation division of the board applied sim-



plification to more than 300 commodity lines with enormous savings to industry. (*See* B. M. Baruch, *American Industry in the War,* U.S. Government Printing Office, 1922.) After the war, many of the industries which had participated in the Government's programme and had benefited by simplification, wishing to continue this waste-elimination programme, turned to the U.S. Chamber of Commerce. (*See* WAR CONTROL OF INDUSTRY.)

Early in 1921, Herbert Hoover, then president of the American Engineering council (the executive body of the Federated American Engineering Societies), organized a committee of 17 well-known industrial and management engineers to make a survey of waste in industry. The committee studied six major industries and found wastes ranging from 29% in the metal trades to 64% in the manufacture of men's ready-made clothing. Avoidable waste, according to the committee's evaluation, amounted to 41% in boot and shoe manufacture, 49% in the textile, 53% in the building and 58% in the printing industry. Among the outstanding causes for waste in these fields was the unnecessarily great variety in sizes, etc. The committee therefore suggested that the Federal Government call together representatives of trade associations in inter-dependent industries and form committees to effect simplifications in their commodities. (See *Waste in Industry,* McGraw-Hill Book Co., 1922.)

When Hoover became secretary of commerce he was requested by many business leaders to assist industries to apply simplification. Accordingly, he organized the division of simplified practice. In Nov. 1921, varieties of vitrified paving-brick were reduced from 66 to 11, which constituted the bulk of the output.

A general conference of brick producers, highway engineers, and officials agreed thereafter to concentrate on the 11 most popular sizes. In March 1922, a second conference reduced the number to 7; in Jan. 1928, only 5 varieties were listed. (See *Trade Association Activities,* Domestic Commerce series no. 20, U.S. department of commerce, 1927.) Meantime, simplification through group co-operation has been applied to 80 other commodities, with elimination of superfluous variety ranging from 25% in some instances to 99% in others, as shown in part in the following tables:—

Simplified Practice Applied to Construction Materials

Commodity	Varieties		
	Formerly	Now	Reduction
			%
Paving bricks	66	5	94
Asphalt	102	10	90
Steel reinforcing bars	40	11	72½
Metal lath	125	24	81
Woven wire fence	552	69	87
Asbestos millboard	10	5	50
Eave trough and conductor pipe	21	16	24
Concrete building units	115	24	80
Sand lime brick	14	3	78½
Roofing slate	98	48	51
Average reduction	..	..	71

Simplified Practice Applied to General Supplies and Furnishings for Homes, Hotels, Hospitals, Clubs, etc.

Commodity	Varieties		Reduction
	Formerly	Now	
			%
Bedsteads, springs and mattresses	78	4	95
Bed blankets	78	12	85
Sterling silver flatware	190	62	67
Tinware, galvanized japanned	1,154	873	24
Milk bottles	49	9	82
Milk bottle caps	29	1	96
Hotel china-ware	700	160	77
Restaurant china-ware	668	177	73
Dining car china-ware	700	113	84
Hospital beds	67	4	94
Steel lockers	65	17	74
Average reduction	..	..	76½

One manufacturer of electrical apparatus eliminated 49% of the items in his stocks. An important Western road reduced its stores, releasing $18,000,000 of otherwise idle investment.

A shoe manufacturer making 3 grades of shoes in 2,500 styles cut his varieties to one grade of 100 styles, thereby reducing his production cost 31%, direct overhead 28%, inventories 26% and cost to consumer 27%. This enabled him to increase his turnover 50%; women's shoes 22%; and men's 80%.

Simplification, now widely recognized in America, is also being

studied, and to some extent applied, by business interests in other countries. Many economists regard the increasing application of simplification as a significant factor in the advancing standard of living, since the savings it yields are passed on to the ultimate consumer in higher wages and lower prices.

FROM THE POINT OF VIEW OF THE CONSUMER

Let us agree at once and frankly with the social critics that standardized behaviour patterns, moving-picture plots, syndicated editorials, slavery to advertised styles, political speeches, educational rolling mills, are an unmitigated evil, but when it comes to the kind and the quality of the goods which the public buys, we enter a different, more limited field, and one where standards of workmanship have a definite and valuable place Women should not wear identical frocks; but no aesthetic values are lost if a woman has standards to guide her in respect to the durability, the fullness of measurement, the fastness of dyes, the silk content of materials. Standards often improve a product because, due to stability of demand, the product can be built with more specialized and more precise tools, and with more research behind it, than is the case with small quantities and excessive varieties For nicety of workmanship and exact adaptation to its function, the present-day lamp bulb, vacuum-tube or fine watch has no counterpart in handicraft industry The U S Chamber of Commerce has estimated that one-quarter of all industrial effort in America is wasted because of irrelevant over-diversification of styles, types and sizes. This refers to the labour of approximately 5,000,000 people, and a full 25% in the cost of living. (S CH; F. J. S)

STANDARD OF LIVING. The term "Standard of Living" has two distinct meanings. As used by the leading economists from Ricardo to the present day, it has a strictly technical meaning It also has a loose, general and semi-popular meaning In the strictly technical sense it means the scale of living which the average individual of any given group considers preferable to marriage, or which he must be sure of maintaining before he will marry and undertake the support of a family. In the loose and general sense it means merely the list of things which the average individual of any given class happens to be consuming at a given time and place. In the technical sense, it is a dynamic factor in determining the density of population, the labour supply, the rate of wages, and the possibility of future improvement of economic conditions. In the general sense it is merely a description of the way people are actually living in a given time and place. It is useful in determining what income is necessary in order to support a family according to a standard of living which the estimator deems necessary or satisfactory

In the strictly technical sense, a man who will marry and beget children without any regard whatsoever to his ability to provide for the needs of wife and children, has, literally, no standard of living at all. It is safe to say that the only creatures who thus thoughtlessly mate and breed are those which, like plants and animals, lack the capacity for thinking of the future. A standard of living, in this technical sense, is something which goes with intelligence and foresight

Similarly, those who will marry and undertake the support of families as soon as they feel able to provide the bare necessaries of life are said to have a low standard of living Conversely, those who will not marry until they are reasonably certain of being able to afford a great many luxuries as well as all the necessaries and decencies of life, are said to have a high standard of living. Thus a standard of living is always relative and consists of the number of desirable things which the individual considers more desirable than the domestic satisfactions which come with marriage. A high standard of living may result either from a weakening of sex and domesticity or from a strengthening of the desire for other things, while a low standard may result either from exaggerated sexual and domestic desires or from weakened desires for other things

It is obvious, to begin with, that standards of living, as thus technically conceived, have a profound influence upon the economic well being of nations and of classes within a nation. If the standard of living of every individual of a group, either territorial or occupational, is high, it insures the group against over-population. If, for example, no one would marry and undertake the support of a family until he was reasonably certain of being able to educate his children, to house them comfortably, and provide them with a motor car, it is reasonably certain that no children would be legitimately born except in families which could afford these things. Besides, such a country, in the absence of immigration, would never have any more people than could afford these things Disasters and bankruptcies might reduce some to want, but normally there would be no want. On the other hand, if every one would marry and undertake the support of children as soon as he was able to provide a bare physical subsistence, it is certain that a great many children would be born in families which could only afford bare physical subsistence. In other words, wide spread poverty would be the normal state of large masses of people.

In the above characterization we have coupled both sex and domesticity as factors in a low standard of living. In a rather strict and narrow sense however, it is a relatively strong sexual desire rather than a high development of domesticity which characterizes a low standard of living A highly developed domesticity would lead an intelligent person to desire not merely children, but the welfare of his future children. This would lead to some postponement of marriage until one could provide for their welfare

The items which go to make up a high standard of living include other things than material articles of consumption. Those who will not marry until, as suggested above, they are reasonably certain of being able to educate their children, have a high standard of living. Such a desire to safeguard the welfare of their future children has the same effect on marriage rates and marriage ages as the desire for beefsteak and race track tickets Even a high degree of thrift may be a mark of a high standard of living. He who will not marry until he can afford a sizeable insurance policy or bank account may be called a thrifty individual, but he also has a high standard of living. In such a case the desire for an insurance policy or a bank account has the same effect on the postponement of marriage as the desire for a motor car or an eight-room house and must be accounted as a part of a high standard of living Certain it is that if no one would marry until he had an insurance policy or a bank account, no children would be legitimately born except in families which, at one time at least, had insurance policies or bank accounts. There would generally be no poverty except as the result of unforeseen disasters which dissipated savings and cut off incomes out of which savings were made.

It is well to remember that this balancing of sex against other desires is conditioned upon an economic system which imposes parental responsibility. If one did not have to pay the expenses of his own family, no other desires would have to be sacrificed when the procreative desires were gratified

Different nations, and different classes within each nation may have different standards of living in the strict as well as in the general sense of the term There are, however, no statistics available which throw any very direct light on these differences in the stricter sense. Some indirect light is thrown on the subject by an exceedingly valuable study by Baber and Ross on "Changes in the Size of American Families in One Generation" (University of Wisconsin Studies in the Social Sciences and History, No. 10. Madison, 1924). Tables are included which show that farmers and laborers tend to marry earlier than business and professional men; other tables show that on the average, more children are born of early than of late marriages.

Family budgets as evidences of the spending habits of people with different incomes, were the first records to be studied statistically with a view to determining standards of living. The most famous of these is that of Dr. Ernst Engel. The following table summarizes the general results of that study.

Items of expenditure	Percentage of expenditure of family income		
	$225–$300	$450–$600	$700–$1,000
Subsistence	62·0 } 95·0	55·0 } 90·0	50·0 } 85·0
Clothing	16·0	18·0	18·0
Lodging	12·0	12·0	12·0
Heat and light	5·0	5·0	5·0
Education, public worship, etc.	2·0 } 5·0	3·5 } 10·0	5·5 } 15·0
Legal protection	1·0	2·0	3·0
Care of health	1·0	2·0	3·0
Comfort and recreation	1·0	2·5	3·5
	100·0	100·0	100·0

From Ernst Engel, ***Prussian Statistical Bureau Report No. 1857,*** p. 145, Table I.

The only striking thing about this table is that it shows that as incomes increase the percentage spent for the basic necessaries decreases while the percentage spent for education, health, comfort, etc., increases.

A fairly clear idea of the comparative standard of living of different countries and at different times may be gained from a study of the relative cost of living. Changes in the cost of living in Great Britain from 1915 to 1926 have been calculated by the Ministry of Labour. The following table is a condensation of their findings:

*Index Numbers of the Cost of Living in Great Britain Calculated by the Ministry of Labour**
July, 1914 = 100

Date	Food	Housing	Clothing	Fuel and light	Other items	Total cost of living
1915	132	100	125	125	105	125
1916	161	100	160	135	120	145–150
1917	204	100	205	140–145	140	180
1918	210	102	320	175–180	180	200–205
1919	209	106	360	185–190	195	205–210
1920	258	115–120	425	230	220	252
1921	220	145	290	260	210	219
1922	180	153	240	190	195	184
1923	162	147	220	180–185	185	169
1924	162	147	225	185	180	170
1925	167	147	230	180	180	173
1926	161	150	220	195	180	170

*The figures are for July of each year.

A comparison of the changes in the cost of living in different countries is contained in the following table. These, together with the statistics of wages, furnish the best information available as to the standards of living of wage workers in those countries:

*Cost of Living in Different Countries, *1914–1926*
1914 = 100

Year	Germany	Canada	France	United Kingdom	United States	Switzerland
1914	100	100	100	100	100	100
1915	..	97	..	125	105	119
1916	..	102	..	148	118	140
1917	..	130	..	180	142	180
1918	..	146	..	210	174	229
1919	..	155	238	215	199	261
1920	..	190	341	255	200	253
1921	..	152	307	222	174	209
1922	..	146	302	181	170	158
1923	..	146	334	171	173	167
1924	116·0	143	366	171	173	166
1925	143·3	146	390	173	178	165
1926	139·8	155	..	173	..	..

*From the ***"Monthly Bulletin of Statistics, League of Nations,"*** No. II. February, 1926. Page 67.

The changes in the cost of living have been compared with the changes in money wages in order to give the trend of real wages in various countries. *Cf.* the ***International Labour Review,*** 1927, Page 107.

A somewhat more elaborate study was made in 1909 by Robert Coit Chapin in his *Standard of Living in New York City*, page 70. The following is a brief summary of his more elaborate table:

Expenditures of Families in New York City

Income group	Rent, per cent	Carfare, per cent	Fuel and light, per cent	Food, per cent	Clothing, per cent	Insurance, per cent	Health, per cent	Sundries, per cent
$ 400–$ 499	26·8	2·6	5·6	40·8	13·0	1·2	3·1	6·9
500– 599	25·9	1·8	5·9	44·4	12·4	1·3	1·9	6·4
600– 699	23·6	1·7	5·8	44·6	12·9	2·0	2·1	7·3
700– 799	21·9	1·5	5·0	45·6	13·4	2·5	1·9	8·2
800– 899	20·7	2·0	5·0	44·3	14·0	2·2	2·7	9·1
900– 999	19·0	1·5	5·1	44·7	14·6	2·6	2·6	9·9
1,000– 1,999	18·1	1·8	4·5	44·7	15·5	2·5	1·5	11·4
1,100– 1,199	16·2	1·9	3·8	45·6	14·9	2·5	3·6	11·5
1,200– 1,299	19·8	2·2	3·8	45·0	15·2	2·2	1·3	10·5
1,300– 1,399	16·8	1·1	3·6	43·6	13·7	4·9	1·1	15·2
1,500– 1,599	16·3	1·2	4·1	36·8	16·8	2·3	7·4	15·1

Numerous other studies have been made, notable among which are those of Henry Higgs, "Workingmen's Budget," *Journal of the Royal Statistical Society*, 1893; Louise Bolard More on *Wage Earner Budgets*, N.Y. 1907; Frank Hatch Streightoff on *The Standard of Living among the Industrial People of America*, Boston, 1911; William C. Beyer, Rebekah P. Davis and Myra Thwing on *Workingmen's Standard of Living in Philadelphia*, N.Y., 1919, and a symposium by various writers on *Standards of Living; a Compilation of Budgetary Studies*, published by the Bureau of Applied Economics, Washington, 1920.

On the basis of these studies of actual budgets, various estimates have been made as to the money income necessary at existing prices to enable an average family to maintain a satisfactory standard of living. Of course something depends upon what the estimator considers a satisfactory standard. One of the best of these estimates was made by Robert Coit Chapin in 1909. His estimate was that in New York City in that year $900.00[1] was necessary. Various other estimates, based on different price levels and costs of living are tabulated by Paul Douglas in his *Wages and the Family*[2]. A summary of this tabulation follows:

Total Amounts Required to Support the Standard Family of Five According to Various Budgets

Year	City	Investigator	Amount of budget	
			Subsistence plus health and decency	Comfort
1913–15	Philadelphia	Cotton and Little	$1,070	..
1917	San Francisco	Peixotto	1,476	..
1918	Philadelphia	Beyer	1,637	..
1919	Washington	U.S. Bureau of Labor Statistics	..	$2,262
1919	Lawrence, Massachusetts	Nat. Ind. Conf. Board	1,658	..
1920	Cincinnati, Ohio	Nat. Ind. Conf. Board	1,692	..
1920	Chicago, Illinois	Council of Social Agencies	1,666	2,322
1920	San Francisco, Los Angeles, and Sacramento	Blum and Peixotto	..	2,292
1921	Philadelphia, Pa.	Beyer	1,847	..
1922	Anthracite region of Pennsylvania	Nat. Ind. Conf. Board	1,322	..

It is frequently asserted that because the well-to-do classes have a low and the poor a high birth rate, the difference in wealth is

[1]Cf. *The Standard of Living Among Workingmen's Families in New York City*, p. 246.
[2]Chicago, 1925, pp. 7 and 8.

the cause of the difference in the birth rate On the mere ground of probability it would be at least as likely that the causal connection is the exact reverse, or that the difference in the birth rate is the cause of the difference in prosperity. There are some rather strong reasons for believing that, *in the same economic class,* an increase of prosperity increases rather than decreases the birth rate. If, without first raising the standard of living, in the strictly technical sense, a given economic class is provided with larger incomes, the larger incomes are used as a means of earlier marriages and larger families.

From Malthus to the present day, it has been recognized that a low standard of living among the working classes was the chief hindrance to the success of schemes of social betterment. Efforts to improve the condition of backward peoples are clearly frustrated by their enormous fecundity. During 40 years of British rule in Egypt, 1882–1922, the population doubled. This was made possible by irrigation and other economic improvements. Had the population not doubled, the lot of the masses might have been greatly improved But with a low standard of living, the increased food supply merely resulted in a greater excess of births over deaths with no great improvement in the average well being Similar results followed British rule in India, the French control of Algeria, the American occupation of the Philippines and Porto Rico. In every case, there has been a phenomenal increase in population, with no apparent change in the standard of living The net result is, as Ross so expressively states,[1] *"The white race is today serving as a midwife to the blacks and the browns"*

If the standards of living of the blacks and the browns could have been raised while the productivity of their countries was being increased, the results would have been different. Instead of merely increasing the number of people living a miserable existence, white control would have lifted those people to a higher state of comfort Similar results seem to follow from most so-called humane movements for the improvement of the condition of the lower classes of labourers within advanced countries. So long as the standard of living remains low and men will marry as soon as they are assured of sufficient income to satisfy the basic necessaries of life, any improvement in wages or employment is likely to result merely in earlier marriages and larger families with a consequent increase in the supply of labourers followed by a reduction of wages to the old level On the other hand, if the reform can start with, or be accompanied by, a rise in the standard of living, this train of evil consequences will not follow. The real question, therefore, upon which the success of most schemes of social amelioration depends, is, Can the standard of living of the mass of the labourers be raised? For the more intelligent portion of the labouring classes the raising of the standard of living is not only feasible but offers the most effective means of social amelioration For the less intelligent classes, those bordering on feeblemindnesses, some more drastic method will have to be employed to prevent the overstocking of the labour market. (T N. C.)

STANDARD OIL COMPANIES, American petroleum corporations which were formerly a single group operating throughout the world under the ownership of Standard Oil Company of New Jersey In 1911 the United States Supreme Court ordered the dissolution of this company under provisions of the Sherman Anti-Trust Act and shares of 33 subsidiaries were distributed to stockholders of the company Since that time there has been a gradually decreasing community of interest among the different units, and the ownership of the shares, originally in the same hands as the shares of the Standard Oil Company of New Jersey, has become widely diversified In 1929 the largest interest in Standard Oil Company (N J) stock controlled but 11% of its shares, and this interest had disposed of all of its holdings in some of the other units There was no officer or director holding a place in the management of two or more of the companies and each company has pursued an independent career Many of the companies formerly aligned are engaged in spirited competition, one with the other Notably, Atlantic Refining Company has gone into direct competition with Standard Oil Company of New York and Standard Oil Company of New Jersey, in the fields formerly reserved to those units. Standard Oil Company of New Jersey has recently entered the State of Pennsylvania, formerly occupied exclusively by Atlantic Refining, and is engaged in building up its own retail distributing organization in that State. Standard Oil of Indiana is in active competition both for production and retail business with several of its former associates. The Vacuum Oil Company is competing for lubricating oil business against all the other companies. The largest of the former members of the Standard Oil group now does but a very small percentage of the total business of the country.

Some of the principal Standard Oil Companies are Standard Oil Company (N J), Standard Oil Company (Indiana), Standard Oil Company of New York, Standard Oil Company of California, Standard Oil Company of Ohio, Vacuum Oil Company, Atlantic Refining Company, Prairie Oil and Gas Company. The first named is the largest of the former units, with assets of approximately $1,500,000,000. Its business is about half domestic and half foreign, the domestic business being done chiefly in the middle Atlantic States, which are best served by its seaboard refineries. This is now exclusively a holding company which owns numerous subsidiary companies that produce, transport, refine and market petroleum and its products. Prominent among these subsidiaries are Standard Oil Company of New Jersey, Standard Oil Company of Louisiana, and Standard Oil Company of Pennsylvania, all 100% owned The holding company has a majority interest in Humble Oil and Refining Company, Beacon Oil Company, Creole Petroleum Corporation, Imperial Oil Ltd , and various other operating companies. It is a large operator of tankers, having the greatest private tonnage under the American flag.

Standard Oil Company of Indiana operates directly in eleven States in the middle west and through subsidiaries in many other areas where it competes with former units of the trust It has total assets in excess of $500,000,000. Standard Oil Company of California is an important producing, refining and marketing company which is chiefly operating on the Pacific coast. It too operates a large number of tankers.

STANDARD PRICE: *see* PRICE MAINTENANCE.

STANDARDS, NATIONAL BUREAU OF. This United States body was established by act of Congress on March 3, 1901, and has for its functions the development, construction, custody and maintenance of reference and working standards, and their intercomparison, improvement and application in science, engineering, industry and commerce. The bureau is a part of the Department of Commerce Its services are available without charge to the national and State Governments, and under certain conditions, tests and investigations are conducted for the public. In the case of tests for other than the national and State Governments, fees are charged which are paid in to the U.S. Treasury The original staff of the bureau of standards numbered 14 persons. In 1928 there were about 850, of whom two-thirds were technically trained. The plant comprised 14 permanent buildings on a site of 43 ac in the north-west suburbs of Washington.

The bureau serves as a clearing house for scientific and technical information and to this end co-operates with similar institutions abroad and with the research laboratories of American industries. Large industrial groups send representatives to work in the bureau's laboratories on problems of mutual interest, the results of which are published for the public benefit. The laboratory equipment is unusually complete and includes several small-scale manufacturing plants in which mill processes can be studied.

Scope.—The bureau's work falls into two major classes, the first comprising scientific and technical research and testing, and the second the establishment of commercial standards. Each of these major groups includes several divisions which in turn are made up of sections, the section being the working unit dealing with some specific class of problems. The research and testing group consists of the following divisions: electricity, weights and measures, heat and power, optics, chemistry, mechanics and sound, organic and fibrous materials, metallurgy and ceramics. The commercial standards group is composed of the follow-

ing units: simplified practice, building and housing, specifications, commercial standards; and members of the staff co-operating with such organizations as the Federal Specifications Board and the American Marine Standards committee. In addition to these two groups there are divisions concerned with the administrative work of the central office, the operation of the bureau's plant and the construction of apparatus.

Achievements.—Through conferences held during the past 23 years, practical uniformity in weights and measures has been secured throughout the country. In this connection it should be remembered that the Bureau of Standards has no police power.

Many contributions have been made to the art of radio communication, particularly as regards the fundamental data underlying the propagation of radio waves, and the measurement and control of frequency. Recently a new type of radio beacon has been developed by which aircraft are guided in fog and by which the pilot can tell when he is following the desired course.

Contributions have been made to the art of manufacturing railroad rails, car wheels, boiler plate and other metallurgical products. A means for greatly retarding the corrosion of duralumin, the light alloy used in the construction of aircraft, has been developed, and the plating of metals with chromium has been made a commercial success.

The bureau constructed the first altitude laboratory in the world for testing aircraft engines under flight conditions. In this laboratory the low air pressure and temperatures existing at high altitudes can be duplicated and the performance of the engine determined. The results obtained in this laboratory were of the greatest value in assisting in the design of aeroplane engines during the World War.

The bureau's polarimetry section has made many fundamental discoveries in the field of carbohydrates. A commercial method was developed for the production of corn-sugar (dextrose) and this is now a most important industry. Similar work is now in progress on levulose (sugar obtained from a weed, the Jerusalem artichoke) and experiments will soon be possible on a commercial scale. Revolutionary developments are expected to follow as the sugar has many advantages over cane-sugar for certain uses.

In 1914 experiments were started on the making of optical glass, and in three years the bureau was able to turn out good grades of glass in all the usual varieties. This work has been continued and recently there was cast at the bureau the largest disc of optical glass ever made in this country, 70 in. in diameter and 11 in. thick. This will be used as the mirror of the reflecting telescope at Perkins observatory, Ohio Wesleyan university.

On the experimental paper-mill, a paper on which to print American currency has been developed which shows a strength of 40% greater than the paper formerly used. In co-operation with the Iowa State College experiments are in progress on the manufacture of wall board from corn stalks, and on recovering other valuable products from waste material of the farms.

At the last meeting of the International Conference on Weights and Measures at Paris, in 1927, the bureau was largely responsible for the adoption of a uniform international temperature scale, and for the tentative adoption of a value of the international metre in terms of the wave length of light.

The publications of the bureau can be purchased from the superintendent of documents, Government printing office, Washington, D.C. (*See* STANDARDIZATION.) (G. K. B.)

STANDARDS DEPARTMENT. A department of the English Board of Trade, having the custody of the imperial standards of weights and measures. As far back as can be traced, these were in charge of the chamberlains of the exchequer. This office was abolished in 1826, but the custody of the standards remained attached to an officer in the exchequer (*q.v.*) until that department was abolished in 1866. Meanwhile, in pursuance of recommendations of Standard Commissions of 1841 and 1854 and a House of Commons committee of 1862, the Standards of Weights, Measures and Coinage Act, 1866, was passed. This act created a special department of the Board of Trade, called the "Standard Weights and Measures Department." The Weights and Measures Act of 1878 made the office more strictly a department of the Board of Trade.

The functions of the standards department include the custody of the imperial standards, the periodical comparison of these with their parliamentary copies and the verification and re-verification of local standards and scalebeams for local authorities and of any standards submitted by other bodies in this country or by any colonies or foreign countries. The types of apparatus accepted for verification include standard weights, measures, weighing and measuring instruments, gas-measuring standards and apparatus for determining the flash-point of petroleum. Under the Weights and Measures Act 1904, the department is charged with the duties of examining and certifying candidates nominated by local authorities for appointment as inspectors of weights and measures or inspectors of gas meters; the making of regulations with regard to the verification and stamping of weights, measures and instruments for use in trade, the tests to be applied, the limits to be allowed and the conditions under which stamps are to be cancelled; also the examination and certification of novel patterns of weighing or measuring apparatus with reference to fraud.

There are also standards departments under the charge of experienced scientists in Berlin, Leningrad, Paris, Vienna, Rome, Madrid, Washington and elsewhere. The United States Bureau of Standards is in the Department of Commerce and Labor. (*See* STANDARDS, NATIONAL BUREAU OF.)

STANDERTON, a town in South Africa on the Vaal river, here spanned by two bridges, 114 m. by rail S.E. of Johannesburg; altitude 5,022 feet. It is the chief town of a district of the same name and the centre of an agricultural and of a coal-mining region.

STANDISH, MILES or MYLES (*c.* 1584–1656), American colonist, was born about 1584 in Lancashire, England. He emigrated to New England in the "Mayflower" in 1620 with the Pilgrims, and became the military leader of the Plymouth colony. He was sent to London in 1625 on an unsuccessful mission to secure the intervention of the Council for New England in the affairs of the colony; and in 1628 was one of the eight members of the colony who pledged themselves to pay £1,800 and thus buy out the merchant adventurers who had financed the colony. In 1631 with William Brewster and others he settled at Duxbury, where he died on Oct. 3, 1656, and where on "Captain's Hill" there stands a monument to him.

Longfellow's *Courtship of Miles Standish* apparently has no basis in fact, and Lowell's *Interview with Miles Standish* misrepresents him; he was not a typical Puritan.

See William Bradford's *History of Plimouth Plantation.* Tudor Jenks's *Captain Myles Standish* (1905) and Henry Johnson's *Exploits of Myles Standish* (1897) are popular sketches.

STAND PAT, a term used in American politics, signifying the act of opposing progressive or advanced policies. It originated in the latter part of President Roosevelt's administration when certain progressive or insurgent members of the Republican Party, mostly representatives and senators in Congress, from States west of the Mississippi, called the conservative members of the party "standpatters."

STAND-PIPE is a vertical pipe coupled to a ground hydrant, to lead off water suitably for filling buckets, street-watering hose, fire-hose, watering-carts, etc. The pipe is either permanent or detachable, and the top may be of fixed or swivel type, with one or more outlets. A tall bent pipe is sometimes attached for filling watering-carts or small locomotives. A stand-post is often combined with a drinking fountain or with a lamp column. In either case space is saved and in the latter event the lamp serves as a quick indication of the spot for fire-hose application. In cold climates special construction is necessary, the valve being placed well below the ground. (*See* HYDRANT.)

STANFIELD, WILLIAM CLARKSON (1794–1867), English marine painter, was born of Irish parentage at Sunderland in 1794. As a youth he went to sea, but he practised sketching to such good effect that, on being incapacitated by an accident, he was able to paint scenery at the "Old Royalty," a sailors' theatre in Wellclose Square, London, the Coburg theatre, Lambeth, and at Drury Lane. His first easel exhibit was "Wreckers off Fort Rouge" at the British Institution in 1827, and in 1832 he was

made A R A and in 1835 R A He died on May 18, 1867 His art was influenced by his early scene painting and tends to be spectacular and dry and hard in colour; on the other hand the treatment is broad and effective.

His principal works are: "Mount St. Michael", "The Opening of London Bridge" and "Portsmouth Harbour" (1832), "The Battle of Trafalgar" (1836) for the United Service Club, "Isola Bella" (1841), "The 'Victory' bearing the Body of Nelson towed into Gibraltar" (1853) and "The Abandoned" (1856). *Stanfield's Coast Scenery* contains 40 of his works engraved in line.

STANFORD, SIR CHARLES VILLIERS (1852–1924), Irish composer, was born in Dublin on Sept. 30, 1852. After studying in London under Ernst Pauer he won (1870) a scholarship at Queen's College, Cambridge, whence he migrated to Trinity College in 1873, and succeeded J L. Hopkins as college organist, a post he held till 1892. His appointment as conductor of the Cambridge University Musical Society gave him great opportunities. In 1874 to 1877 he visited Germany each year, studying under Reinecke and Kiel. His first important composition was incidental music to Tennyson's *Queen Mary* (Lyceum, 1876). In 1881 his opera, *The Veiled Prophet,* was given at Hanover; followed by *Savonarola* (Hamburg and Covent Garden, 1884), and *The Canterbury Pilgrims* (Drury Lane, 1884). A long interval separates these from his later operas, *Shamus O'Brien*, the least pretending but most successful of all his dramatic works (Opéra Comique, 1896) and *Much Ado About Nothing* (Covent Garden, 1901).

Meanwhile he had been appointed professor of composition at the Royal College of Music in 1883; conductor of the Bach choir in 1885; professor of music in the university of Cambridge, succeeding Sir G. A Macfarren, in 1887; conductor of the Leeds Philharmonic Society, in 1897, and of the Leeds Festival from 1901 onwards. He was knighted in 1902 and died in London on March 29, 1924 His instrumental works include six symphonies, many chamber compositions, among them two string quartets; besides many songs, part-songs, madrigals, etc , and incidental music to the *Eumenides* and *Oedipus Rex* (as performed at Cambridge), as well as to Tennyson's *Becket* His last operatic work was *The Travelling Companion,* posthumously produced in 1926 His church music and editions of Irish and other songs are well known.

See his *Studies and Memories* (1908), and *Pages from an Unwritten Diary* (1914).

STANHOPE, CHARLES STANHOPE, 3RD EARL (1753–1816), English statesman and scientist, was born on Aug 3, 1753, and educated at Eton and Geneva, where he studied mathematics In politics he was democratic; he represented High Wycombe from 1780 until his accession to the peerage in 1786, giving his support (1783–84) to the administration of Pitt, whose sister, Lady Hester Pitt, he married in 1774, but when Pitt forsook his Liberal principles, Stanhope severed their political connection. He was the chairman of the "Revolution Society," which expressed its sympathy, in 1790, with the aims of the French Republicans, and in 1795 he introduced into the Lords a motion deprecating any interference with the internal affairs of France, on which point he was in a "minority of one." He thereupon retired from politics for five years He spent much money on experiments in science and philosophy His inventions include the printing press and the lens which bear his name, a monochord for tuning musical instruments, and two calculating machines He projected a canal through Devonshire, and took the levels himself. His writings include *Principles of Electricity* (1779), a reply to Burke's *Reflections on the French Revolution* (1790); and an *Essay* on the rights of juries (1792). The lean and awkward figure of Lord Stanhope figured in a host of caricatures. His first wife died in 1780, and in 1781 he married Louisa, daughter and heiress of the Hon. Henry Grenville, who survived him, and died in 1829 Lady Hester Stanhope (*q v.*) and Lady Lucy Rachael Stanhope, who eloped with the family apothecary and was never reconciled with her father, were daughters by his first wife. Lord Stanhope died at Chevening, Kent, on Dec 15, 1816.

See G. P Gooch, *Life of Charles, 3rd Earl Stanhope* (1914).

STANHOPE, LADY HESTER LUCY (1776–1839), the eldest child of the 3rd Earl Stanhope by his first wife, Lady Hester Pitt, was born on March 12, 1776, and lived at her father's seat of Chevening in Kent until early in 1800, when his excitable and wayward disposition drove her to her grandmother's house at Burton Pynsent. In 1803 she became the chief of the household of her uncle, William Pitt. Although her wit and beauty cheered his declining days, her satire created enemies. Lady Hester Stanhope possessed great business talents, and when Pitt was out of office she acted as his private secretary. On his death she was granted a pension of £1,200 a year, dating from Jan 30, 1806. On Pitt's death she lived in Montagu Square, London, but in 1810, she left England for ever. After many wanderings she settled among the Druses on Mt. Lebanon, and from the lonely villa of Djoun, 8 m. from Sidon, she wielded an almost absolute authority over the surrounding districts, maintained by her commanding character and by the belief that she possessed the gift of divination. Ibrahim Pasha, when about to invade Syria in 1832, solicited her neutrality. She died on June 23, 1839. Her disappointments and her dictatorship intensified a temper naturally imperious. In appearance as in voice she resembled her grandfather, the first Lord Chatham.

Some years after her death there appeared three volumes of *Memoirs of the Lady Hester Stanhope as related by herself in Conversations with her Physician* (Dr Meryon, 1845), and these were followed in the succeeding year by three volumes of *Travels of Lady Hester Stanhope, forming the Completion of her Memoirs narrated by her Physician.* They presented a lively picture of this strange woman's life and character, and contained many anecdotes of Pitt and his colleagues in political life for a quarter of a century before his death *See* also Mrs. Charles Roundell, *Lady Hester Stanhope* (1910); the Duchess of Cleveland, *Life and Letters of Lady Hester Stanhope* (1914); and F. Hamel, *Lady Hester L. Stanhope* (1913).

STANHOPE, JAMES STANHOPE, 1ST EARL (*c* 1673–1721), English statesman and soldier, the eldest son of Alexander Stanhope (d. 1707), a son of Philip Stanhope, 1st earl of Chesterfield, was educated at Eton and Trinity college, Oxford He served in Italy and Flanders as a volunteer against France, and in 1695 obtained a commission in the British army. Entering the House of Commons in 1701 he still continued his career as a soldier. In 1706 he was appointed British minister in Spain, and in 1708 commander-in-chief there He captured Port Mahon, assisted at the battles of Almenara and Saragossa in 1710, but was forced to capitulate to the French at Brihuega on Dec. 9, 1710, and was imprisoned in Spain for a year.

Returning to England in 1712 he became one of the leaders of the Whig opposition in the House of Commons, and, in 1714, he became secretary of State for the southern department, sharing with Walpole the leadership of the House. In 1716, as George I.'s foreign minister he only just failed to conclude a treaty with France. He was made first lord of the Treasury in 1717, but in 1718 returned to his former office of secretary of State. In 1717 he was created Viscount Stanhope of Mahon, and in 1718 Earl Stanhope. He helped to conclude the quadruple alliance between England, France, Austria and Holland (1718). He died in London on Feb 5, 1721, just after the collapse of the South Sea scheme, for which he was partly responsible, though he did not profit

STANHOPE, PHILIP HENRY STANHOPE, 5TH EARL (1805–1875), English historian, better known as Lord Mahon, son of the 4th earl, was born on Jan. 30, 1805, was educated at Christ Church college, Oxford, and entered parliament in 1830 His chief interest was in literature He was a trustee of the British Museum, and in 1856 proposed the foundation of the National Portrait Gallery, whose subsequent creation was due to his executors He also assisted in the establishment of the Historical Manuscripts Commission, and was president of the Society of Antiquaries from 1846 onwards. In 1855 he founded the Stanhope Essay prize at Oxford His works include. *Life of Belisarius* (1829); *History of the War of Succession in Spain* (1832); *History of England from the Peace of Utrecht to the Peace of Versailles* (1836–53); *Life of William Pitt* (1861–62); and *History of England, comprising the reign of Queen Anne until the Peace of Utrecht* (1870, new ed. 1908), the last two of which remain standard works. Stanhope had unique access to ms authorities, a clear style, and a general impartiality in criti-

cism. He died on Dec. 24, 1875, and was succeeded by his son, Arthur Philip (1838–1905).

STANIMAKA, a town of south Bulgaria, at the foot of the Rhodope mountains. Pop. (1926), 17,333. It is a very old Greek colony; its inhabitants speak a dialect containing otherwise obsolete classical terms. On the hill above the town is "Tsar Asen's tower" (*see* ASEN). This was a very strong fortress, and here Renier of Trit, the Latin Count of Philippopolis, was besieged for nine months, until relieved by Villehardouin (*q.v.*). A few miles up the valley of the Čepelare is the monastery of Bačkovo, the second in Bulgaria, with a famous library.

STANISLAUS I. [LESZCZYNSKI] (1677–1766), king of Poland; born at Lemberg in 1677, was the son of Rafael Leszczynski, palatine of Posen, and Anne Catherine Jablonowska. He married Catherine Opalinska by whom he had one daughter. In 1697, as cupbearer of Poland, he signed the confirmation of the articles of election of Augustus II. In 1703 he joined the Lithuanian Confederacy against Augustus, and in the following year Charles XII. selected him to supersede Augustus, and by bribery and intimidation secured his election (July 2, 1704). A few months later Stanislaus was forced by a sudden inroad of Augustus to seek refuge in the Swedish camp, but finally on Sept. 24, 1705, was crowned king with great splendour. Stanislaus at once concluded an alliance with Charles, and rendered him some small assistance against the tsar; but he depended entirely on the success of his ally's arms, and after Poltava (1709) the vast majority of the Poles hastened to repudiate him and make their peace with Augustus, and Leszczynski, henceforth a mere pensioner of Charles XII., retreated to Swedish Pomerania. On the restoration of Augustus, Stanislaus resigned the Polish Crown (though he retained the royal title) in exchange for the little principality of Zweibrücken, residing at Weissembourg in Lorraine.

In 1725 Louis XV. of France married Stanislaus' daughter Mary, and supported his claims to the Polish throne after the death of Augustus II. in 1733, which led to the war of the Polish Succession. On Sept. 9 1733 Stanislaus himself arrived at Warsaw, having travelled through central Europe disguised as a coachman, and on the 10th was once more elected king of Poland. Russia, however, protested, proclaimed the Saxon candidate king as Augustus III. (June 30, 1734), and in October besieged Stanislaus with his partisans in Danzig. The expected French help did not arrive until May 20, 1735, when a fleet disembarked a small force, which, however, could do little. On June 30 Danzig capitulated unconditionally after a stubborn resistance of 135 days. Stanislaus, disguised as a peasant, had contrived to escape two days before. He attempted to rally his partisans from Königsberg, and to secure fresh help from France and from Count Potocki in the Ukraine, but without avail.

In 1736 Stanislaus again abdicated the throne, but received by way of compensation the dukedom of Lorraine and Bar, which was to revert to France on his death. He settled at Lunéville, founded there the *Academia Stanislai*, and devoted himself for the rest of his life to science and philanthropy. He died in 1766 at the age of 89. Among his works may be mentioned: *Oeuvres du philosophe bienfaisant* (Paris, 1763; 1866).

See Robert Nisbet Bain, *Charles XII.* (1895); Louis Lacroix, *Les Opuscules inédites de S. L.* (Nancy, 1866); *Lettres inédites de S. L.*, ed. P. Boyé (1901); Marchioness Des Reaulx, *Le Roi Stanislas et Marie Leszczynski* (1895).

STANISLAUS II. AUGUSTUS [PONIATOWSKI] (1732–1798), king of Poland, the son of Stanislaw Poniatowski, palatine of Cracow, the friend of Charles XII. of Sweden. Through the influence of his uncles the powerful Czartoryski, he was sent to St. Petersburg in the suite of the English ambassador Hanbury Williams. Subsequently, through the influence of the Russian chancellor, Bestuzhev-Ryumin, he was accredited to the Russian court as the ambassador of Saxony. Through Williams he was introduced to the grand duchess Catherine, who was irresistibly attracted to the brilliant young nobleman, for whom she abandoned her other lovers. Poniatowski was concerned in the conspiracy to set aside the succession of the grand duke Peter and his son Paul in favour of Catherine, a conspiracy frustrated by the unexpected recovery of the empress Elizabeth and the consequent arrest of the conspirators.

Stanislaus returned to Warsaw much discredited, but nevertheless was (Sept. 7, 1764) elected king of Poland through the overwhelming influence of Catherine, and crowned on November 25 to the impotent disgust of his uncles. He was hated by the nobility, yet he tried to do his best. He inaugurated some economical reforms. After the first partition he sought to restore the power of their country, while his eloquent oration before the Diet on taking the oath on May 3, 1791, moved the deputies to tears. But when the confederation of Targowica was formed against the constitution, he was one of the first to accede to it, thus completely paralysing the action of the army which, under his younger brother Prince Joseph and Thaddeus Kosciuszko, was performing prodigies. On the outbreak of the insurrection of 1794 he was obliged to sue for his very life to Kosciuszko, and saw his effigy expunged from the coinage a year before he was obliged to abdicate his throne. The last years of his life were employed in his sumptuous prison at St. Petersburg (where he died in 1798) in writing his memoirs. He contracted a secret marriage with the countess Grabowska. He was capable of the most romantic friendships, as witness his correspondence with Mme. Geoffrin.

See Lars von Engeström, *Minnen och Anteckningar*, vol. i. (Stockholm, 1876); *Correspondance inédite de Stanislas Poniatowski avec Madame Geoffrin* (Paris, 1875); Jan Kibinski, *Recollections of the Times of Stanislaw Augustus* (Pol. Cracow, 1899); *Mémoires secrets et inédits de Stanislas Auguste* (Leipzig, 1862); *Stanislaw and Prince Joseph Poniatowski in the Light of their Private Correspondence*, in French, edited in Polish by Bronislaw Dembinski (Lemberg, 1904). Stanislaus's diaries and letters, which were for many years in the Russian foreign office, have been published in the *Vestnik Evropy* for January 1908. *See* also R. N. Bain's *The Last King of Poland and his Contemporaries* (1909).

STANISLAVSKY, stage name of Constantine Sergeevich Alexeev (1863–), Russian theatrical producer, was born in Moscow. His father was a rich mill owner and his grandmother a French actress; he studied at the imperial school of dramatic art and in 1888 began work as an actor and producer in the Society of Art and Literature and after ten years of training founded in 1898 together with the playwright V. N. Danchenko the Moscow Art Theatre. His productions were extremely varied, ranging from the historical *Czar Fedor* to the extreme naturalism of Chekhov's plays. He was also an actor of great force and subtlety, taking the leading parts in Chekhov's and Gorky's plays. Stanislavsky revolutionized the art of producing and is the acknowledged father of the modern Russian theatre.

See Stanislavsky, *My Life in Art* (Eng. trans., 1924).

STANISLAWÓW, a province of Poland. Area 7,090 sq.m. Pop. (1921) 1,349,000, of whom 69·7% are Ruthenians, 22·2% Poles and 6·8% Jews. The Ruthenians speak a different dialect from that of the Ukrainians and the Polesian groups, those in the Carpathian area maintaining their Highland customs, especially the interesting tribes of Hucules, who seem to be of Rumanian admixture. They are members of the Greek Catholic or Uniat Church. The province consists of a fertile belt drained by the tributaries of the Dniester, which forms its north-east boundary, of the Carpathian slopes and the mountains themselves, which rise in height to the east and form the lofty Czarna Hora, with dense forests of beech, fir, etc. The province produces 2,200,000 cubic metres of timber annually, the highest proportion per inhabitant of all the Polish provinces. Stanislawów is famous for its horses and dairy cattle. The salt of Kolomyja has been worked since the earliest times, forming part of the salt belt which extends all along the mountains to Cracow. Potash is found at Kalusz and Turka. The Stanislawów district also has oilfields, producing (1924) 40,495 tons. Other districts, such as Kolomyja, produce oil and there is mineral gas at Kalusz.

The mountain scenery of the province is very beautiful, particularly in the valley of the Stryj. There are a number of health resorts, such as Kosów, in Pokucie. The chief towns are Stanislawów (pop. 1921, 28,200), Stryj (27,300), Kolomyja, Kalusz, Sniatyn and Turka. Halicz (Russian *Galich*), the ancient capital of the three provinces of Stanislawów, Tarnopol and Lemberg, is a small town near the Dniester. It was the capital of a line of

Russian princes, which became extinct in 1340 when Casimir the Great occupied the principality

STANLEY (Family), derived its name from Stanley in Leek (in the Staffordshire "moorlands") Its first known ancestor is Adam de Stanley, brother of Liulf de Audley, who lived in the time of King Stephen His descendant, William de Stanley, acquired the forestership of Wirral, with an heiress, in 1284, and was ancestor of two brothers, Sir William and Sir John Stanley. The former married the heiress of Hooton in Wirral and was ancestor of the Stanleys of Hooton, whose baronetcy, created in 1661, became extinct in 1893. The younger brother, lieutenant of Ireland under Richard II. and Henry IV., obtained from the latter the Isle of Man in fee. His grandson Thomas was father of the first earl of Derby and of Sir William Stanley of Holt, whose great wealth led to his execution for treason in 1495, and also of Sir John Stanley, ancestor of the Stanleys of Alderley, who obtained a baronetcy in 1660 and a barony in 1839. The earls of Derby are noticed under Derby.

The barony of Stanley of Alderley was created in 1839 for Sir John Thomas Stanley, Bart (1766–1850), of Alderley Park. Edward John Stanley, 2nd Baron (1802–1869), entered the House of Commons in 1831 and became under-secretary to the home department in 1841, patronage secretary to the treasury from 1835 to 1841, paymaster-general in 1841, and under-secretary for foreign affairs from 1846 to 1852. In 1848, two years before he succeeded to the barony of Stanley, he was created Baron Eddisbury of Winnington He was president of the board of trade from 1855 to 1858, and postmaster-general from 1860 to 1866. His wife, Henrietta Maria (1807–1895), a daughter of Henry Augustus Dillon-Lee, 13th Viscount Dillon, was a remarkable woman Before her marriage in 1826 she had lived in Florence, and had attended the receptions of the countess of Albany, the widow of Charles Edward, the Young Pretender; and in London she had great influence in social and political circles When he was patronage secretary her husband was described by Lord Palmerston as "joint-whip with Mrs. Stanley." Later in life Lady Stanley of Alderley helped to found the Women's Liberal Unionist Association, and she was a strenuous worker for the higher education of women, helping to establish Girton College, Cambridge, the Girls' Public Day School Company, and the Medical College for Women. She died in 1895

STANLEY, ARTHUR PENRHYN (1815–1881), English divine, dean of Westminster, was born on Dec. 13, 1815, at Alderley, Cheshire, the son of Edward Stanley (1779–1849), afterwards bishop of Norwich. He was educated at Rugby under Arnold, and at Balliol college, Oxford. In 1839 he was elected fellow of University college, also taking orders. In 1840 he travelled in Greece and Italy, and for ten years he was tutor of his college In 1845 he was select preacher, and published in 1847 *Sermons and Essays on the Apostolic Age.* He was a strong advocate of toleration and used his influence to protect from formal condemnation the "Tractarian" party. In 1847 he resisted the movement set on foot at Oxford against R. D. Hampden's appointment to the bishopric of Hereford. Finally, in 1850, in an article in the *Edinburgh Review,* in defense of the "Gorham judgment" he asserted two principles which he maintained to the end of his life—first, "that the so-called supremacy of the Crown in religious matters was in reality nothing else than the supremacy of law," and, secondly, "that the Church of England by the very condition of its being, was not High or Low, but Broad, and had always included and been meant to include, opposite and contradictory opinions."

He was greatly interested in university reform and acted as secretary to the royal commission reporting in 1852. Stanley was also appointed to a canonry at Canterbury During his residence there he published his *Memoir* of his father (1851), and completed his *Commentary on the Epistles to the Corinthians* (1855). In the winter of 1852–53 he made a tour in Egypt and the Holy Land, the result of which was his well-known volume on *Sinai and Palestine* (1856). In 1857 he travelled in Russia, and collected much material for his *Lectures on the Eastern Church* (1861).

At the close of 1856 Stanley was appointed regius professor of ecclesiastical history at Oxford, a post which, with the attached canonry at Christ Church, he held till 1863. He published the first two volumes of his *History of the Jewish Church* in 1863 and 1865. In the storm which followed the publication of *Essays and Reviews* Stanley opposed the High Church Party. In 1836 he published a *Letter to the Bishop of London,* advocating a relaxation of the terms of clerical subscription to the Thirty-nine Articles and the Prayer Book. An act amending the Act of Uniformity, and carrying out in some degree Stanley's proposals, was passed in the year 1865. In 1862, Stanley accompanied the prince of Wales in Egypt and Palestine.

In 1863 he was appointed dean of Westminster. In December he married Lady Augusta Bruce, sister of Lord Elgin, then governor-general of India He wrote a third volume of his *History of the Jewish Church,* a volume on the *Church of Scotland,* another of *Addresses and Sermons* preached in America, and another on *Christian Institutions* (1881). He was constantly fighting for the interests of the poor. He gave offence by defending Bishop Colenso, although he disapproved of Colenso's views, and, still more, by his invitation to the Holy Communion of all the revisers of the translation of the Bible, including a Unitarian among other Nonconformists. He desired that the Athanasian Creed be optional instead of imperative in the Church of England In 1874 Stanley, who was much esteemed by Queen Victoria, conducted the Anglican ceremony at the marriage of the duke of Edinburgh and the grand duchess Marie. He died on July 18, 1881, and was buried in Henry VII 's chapel.

Stanley's other works include: *Life of Dr. Arnold* (1844), *Essays on Church and State* (1870); *Memorials of Westminster Abbey* (1865).

See G. G. Bradley *Recollections of A. P. Stanley* (1883); R. E Prothero and G G. Bradley, *Life and Correspondence of Dean Stanley* (2 vols., 1893).

STANLEY, SIR HENRY MORTON (1841–1904), British explorer of Africa, discoverer of the course of the Congo, was born at Denbigh, Wales, on June 10, 1841, of a family named Rowlands or Rollant John Rowlands, by which name Stanley was baptized, was brought up first by his maternal grandfather, and after his death was boarded out by his mother's brothers at half a crown a week. In 1847 he was taken to the St Asaph Union workhouse, where the schoolmaster, James Francis (who eventually died in a madhouse), was a tyrant of the Squeers type, and in May 1856, Rowlands, after giving Francis a thrashing, ran away from school His paternal grandfather having refused to help him, he became a pupil teacher at Brynford, where his cousin was master. But within a year he was sent to Liverpool, where he lived in poverty with an uncle, and after working at various trades, he sailed as a cabin boy to New Orleans, where he landed in 1859 There he obtained a situation through the good offices of Henry Morton Stanley, who subsequently adopted the lad as his son, but died without making provision for him.

When the Civil War broke out in 1861 Stanley enlisted in the Confederate army; he was captured at the battle of Shiloh (April 1862), and after two months' imprisonment at Camp Douglas, Chicago, he obtained release by enrolling in the Federal artillery In less than a month he was discharged as unfit. In November 1862 he returned to Liverpool "very poor, in bad health and in shabby clothes," and made his way to Denbigh, but was turned away from his mother's door. For a livelihood he took to the sea—was wrecked off Barcelona—and in August 1864 enlisted in the United States navy. After the war he crossed the plains to Salt Lake City, Denver, and other parts, and became a vivid descriptive writer.

Thus began a series of adventures in search of "copy," which led him through Asia Minor, Tiflis and Tibet. In 1860 Stanley revisited Denbigh and St. Asaph, returning thence to America, where he joined General Hancock's expedition against the Red Indians, acting as correspondent for the *Missouri Democrat* and other papers. His reports induced the *New York Herald* to send him to accompany the British expedition of 1867–68 against the emperor Theodore of Abyssinia. Succeeding in sending through the first news of the fall of Magdala, Stanley received a roving commission from the proprietor of the *Herald,* James Gordon Bennett. He went to Crete and Spain, but in 1869 was recalled to Paris by Mr. Gordon Bennett, jun.

Convinced that David Livingstone was alive Bennett commissioned Stanley to go in search of him. But he cumbered Stanley with a large number of commissions in Egypt, Syria and Persia before the quest for Livingstone could be begun. Eventually he sailed from Bombay for Africa, reaching Zanzibar on Jan 6, 1871.

The journey to the interior was begun on March 21; on Nov. 10, having overcome innumerable difficulties, Stanley arrived at Ujiji, where he found Livingstone. With Livingstone Stanley navigated the northern shores of Tanganyika, settled the question as to whether the Rusizi was an effluent or an affluent—a point then much debated in connection with the hydrography of the Nile basin, and regained Zanzibar on May 7, 1872. His story, made public in a picturesque narrative, *How I Found Livingstone* (1872), was received in London with some incredulity; but the journals of Livingstone, which he brought home, silenced the critics, and from Queen Victoria Stanley received a gold snuff-box set with brilliants and her thanks for his services.

A series of public lectures in England and America followed. In 1873, as war correspondent of the *Herald*, he accompanied Wolseley's expedition to Ashanti, which he described, together with his Abyssinian experiences, in a volume entitled *Coomassie and Magdala: Two British Campaigns* (London, 1874). On reaching the island of St. Vincent from Ashanti in 1874 he first heard that Livingstone was dead.

Second African Journey.—Stanley now desired to return to Africa to determine geographical problems left unsolved by the deaths of Livingstone and Speke, and the discovery by Sir Samuel Baker of Albert Nyanza, a lake then reputed to extend illimitably in a southerly direction. A fund was raised by Lord Burnham, Gordon Bennett and others for an Anglo-American expedition under Stanley's command. This expedition lasted from October 1874 to August 1877 and accomplished more than any other single exploring expedition in Africa. Politically the journey led to the foundation of the Congo State and to the partition of the hitherto unappropriated regions of Africa between the states of western Europe. Stanley started from the east coast and reached the ocean again at the mouth of the Congo, having demonstrated the identity of that river with Livingstone's Lualaba by navigating its course from Nyangwe—the point at which both Livingstone and Lovett Cameron had turned aside.

Of the three white men who accompanied him all died during the journey; Stanley himself was prematurely aged. The discovery of the course of the Congo, though the greatest, was but one of many geographical problems solved during this memorable expedition. The part played by the Kagera in the Nile system, the unity and approximate area of Victoria Nyanza, the true length and area of Tanganyika and the whereabouts of its outlet, and the discovery of a new lake, Dweru, which at the time Stanley believed to be a branch of Albert Nyanza, are some of the other discoveries made by Stanley at this time. The story of the expedition was given at length in *Through the Dark Continent* (London, 1878). Stanley's letters from Uganda and his call for missionaries to go to the court of Mtesa met with an immediate response and proved the first step in bringing the region of the Nile sources under the protection of Great Britain. Commercially the discovery of a navigable waterway penetrating the heart of Africa, was of paramount importance, a fact which was grasped by Leopold II., king of the Belgians, who sent commissioners to intercept Stanley at Marseilles, when he was on his way back to England, with proposals to return to the Congo, proposals which Stanley, much needing rest, put aside for the time. In November, 1878, Stanley went to Brussels and entered into the schemes of the Belgian king.

Congo Free State.—A *Comité d'études du Haut Congo* was formed and Stanley was entrusted with the leadership of the new expedition. Stanley reached the Congo in August 1879, and the work he accomplished there in the ensuing five years enabled the comité, which had meantime changed its name to that of *Association internationale du Congo*, to obtain the recognition of America and Europe to its transformation into an independent state ("The Congo Free State") under the sovereignty of King Leopold. Stanley described his labours in *The Congo and the Founding of its Free State* (London, 1885). For the political aspects of the question *see* AFRICA (§ 5) and CONGO FREE STATE. He was restricted by the enterprise of the French traveller de Brazza, who, reaching Stanley Pool by a more northern route, placed the neighbouring districts on the north bank of the Congo under French protection (1880). Stanley returned to Europe in the middle of 1884 and attended the Berlin Conference of 1884-1885, which dealt with African affairs, acting as technical adviser of the American plenipotentiaries.

Third African Journey.—Stanley now became interested in the schemes of Mr. (afterwards Sir) William Mackinnon for establishing a British protectorate in East Equatorial Africa, and it was believed that this object could be furthered at the same time that relief was afforded to Emin Pasha (*q.v.*), governor of the Equatorial Province of Egypt, who had been isolated by the Mahdist rising of 1881–1885. Stanley agreed to conduct an expedition, nominally in the service of the khedive of Egypt, for the relief of Emin. He decided to go by way of Zanzibar and the Congo State. He left Europe in January 1887 and at Zanzibar entered into an agreement with Tippoo Tib, the chief of the Congo Arabs, appointing him governor of Stanley Falls station on behalf of the Congo State, and making another arrangement with him to supply carriers for the expedition. On June 15, Yambuya, on the lower Aruwimi, was reached, and here Stanley left his rearguard under command of Major E. M. Barttelot and Mr. J. S. Jameson. On the 28th Stanley and the advance-guard started for Albert Nyanza, "and until Dec. 5, for 160 days, we marched through the forest, bush and jungle, without ever having seen a bit of greensward of the size of a cottage chamber floor. Nothing but miles and miles, endless miles of forest." Starvation, fever, the hostility of the tribes, were daily incidents of this terrible march, during which Stanley lost nearly 50% of his men. On Dec. 13, Albert Nyanza was reached, and after some delay communication was opened with Emin, who came down the lake from the Nile in a steamer. Disquieted by the non-arrival of his rearguard, Stanley retraced his steps, and on Aug. 17, 1888, a short distance above Yambuya, found that Tippoo Tib had broken faith, that Barttelot had been murdered, that Jameson (who soon afterwards died of fever) was absent at Stanley Falls, and that only one European, William Bonny, was left in the camp.

Collecting those who survived of the rearguard Stanley for the third time traversed the primeval forest, and in January 1889 all that was left of the expedition was assembled at Albert Nyanza. Of 646 men with whom he entered the Congo, but 246 remained. In April the return journey to Zanzibar by way of Uganda was begun, Emin reluctantly accompanying Stanley. On this homeward journey Stanley discovered Ruwenzori (the Mountains of the Moon), traced the course of the Semliki River, discovered Albert Edward Nyanza and the great south-western gulf of Victoria Nyanza. During his stay in the Congo forests he had also obtained much information concerning the pygmy tribes. As to the political results of the expedition, Stanley's proposals to Emin to hold the Equatorial Province for the Congo State or to move nearer Victoria Nyanza and enter the service of Mackinnon's British East Africa Company had not been accepted, but he concluded agreements with various chiefs in the lake regions in favour of Great Britain, agreements which were handed over to the East Africa Company. Zanzibar was reached on Dec. 6, 1889, and the expedition was at an end. *In Darkest Africa*, was published (in six languages) in 1890.

Returning to England, Stanley was received with much honour, and received many distinctions. There was, nevertheless, bitter controversy over the fate of the rearguard of the expedition. On July 12, 1890, he married Miss Dorothy Tennant, second daughter of Mr. Charles Tennant, sometime M.P. for St. Albans. Later in the year he visited the United States, and in 1891–1892 went to Australia and New Zealand on lecturing tours. On his return he was renaturalized as a British subject, and after an unsuccessful attempt in 1892, he was elected member of parliament in 1895. He did not seek re-election in 1900. In 1895 Stanley published *My Early Travels and Adventures in America and Asia*, in

which he retold the story of his experiences with the Red Indians and of his eastern journey of 1869–1870. In 1897 Stanley paid his last visit to Africa. He went to the Cape as the guest of the British South Africa Company, spoke at the opening of the railway from the Cape to Bulawayo, visited the Victoria Falls of the Zambezi and had an interview with President Kruger, of whom he gives a characteristic pen-picture. One result of this journey was *Through South Africa* (1898), the last of his published works. In 1899 in recognition of his services in Africa he was made a K C B The last few years of his life were spent mainly in retirement on a small estate he had purchased, Furze Hill, near Pirbright. He died at his London residence in Richmond Terrace, Whitehall, on May 10, 1904, and was buried at Pirbright. The monolith over his grave bears the inscription. "Henry Morton Stanley 1841–1904" with his African name "Bula Matari" and the one word "Africa."

In geographical discoveries Stanley accomplished more than any other explorer of Africa Notwithstanding his frequent conflicts with Arabs and negroes, he possessed in extraordinary degree the power of managing native races; he was absolutely fearless and ever ready to sacrifice either himself or others to achieve his object. His books differ widely from the ordinary books of travel. Stanley had a gift of dramatic narrative, and his power of portraiture was remarkable. Curiously, the least successful of his works was the only one which he cast in the form of fiction, *My Kalulu, Prince, King and Slave. My Dark Companions and their Strange Stories* (1893) is a valuable contribution to folklore.

The Autobiography of Sir Henry Morton Stanley, ed. by his wife, Dorothy Stanley, appeared in 1909. *Henry M Stanley, the Story of his Life* . . . (London, n d [1872]), by C. Rowlands, contains, notwithstanding many inaccuracies, valuable information concerning his family and early career. The following books may also be consulted: Mrs J. S. Jameson, *Story of the Rear Column of the Emin Pasha Relief Expedition* (1890); W. G. Barttelot, *The Life of Edmund Musgrave Barttelot* . . . (1890); H. Brode, *Tippoo Tib, the Story of his Career in Central Africa* (1907). (F. R. C.)

STANLEY, THOMAS (1625–1678), English poet and philosopher, son of Sir Thomas Stanley of Cumberlow, in Herts, was born in 1625. His mother, Mary Hammond, was the cousin of Richard Lovelace, and Stanley was educated in company with the son of Edward Fairfax, the translator of Tasso. He studied both at Cambridge and Oxford, and travelled widely in Europe. Stanley was the friend and companion, and at need the helper, of many poets, and was himself both a writer and a translator of verse. His *Poems* appeared in 1647; his *Europa, Cupid Crucified, Venus Vigils*, in 1649; his *Aurora and the Prince*, from the Spanish of J. Perez de Montalvan, in 1647; *Oronta, the Cyprian Virgin*, from the Italian of G. Preti (1650); and *Anacreon; Bion; Moschus; Kisses by Secundus* . . . a volume of translations, in 1651. Stanley's most serious work in life, however, was his *History of Philosophy* (3 vols, 1655–61). A fourth volume (1662), bearing the title of *History of Chaldaick Philosophy*, was translated into Latin by J. Le Clerc (Amsterdam, 1690). The three earlier volumes were published in an enlarged Latin version by Godfrey Olearius (Leipzig, 1711). In 1664 Stanley published in folio a monumental edition of the text of Aeschylus He died at his lodgings in Suffolk Street, Strand, London, on April 12, 1678.

The English metaphysical school closes with Stanley, who went on weaving his fantastic conceits in elaborately artificial measures far into the days of Dryden and Butler His *History of Philosophy* was long the principal authority on the progress of thought in ancient Greece

Stanley's original poems were imperfectly reprinted in Sir S Egerton Brydges's edition of 150 copies in 1814. His "Anacreon" was issued, with the Greek text, by Mr. Bullen in 1892.

STANNARIES, tin mines (late Lat. *stannum*, Cornish, *stéan*, tin). Stannary courts exercised a jurisdiction peculiar to Cornwall and Devon. By ancient charters, the tinners of Cornwall were exempt from all other jurisdiction than that of the stannary courts, except in cases affecting land, life and limb. Tin-mining in Cornwall, from the very earliest times was always prosecuted in accordance with a particular code of customs; the earliest charter which embodies them is that of Edmund, earl of Cornwall, but it is impossible to say how far these customs go back.

Twenty-four stannators were returned for the whole of Cornwall. Their meeting was termed a parliament, and when they assembled they chose a speaker. In earlier times the combined tinners of Devon and Cornwall assembled on Hingston down, a tract of highland on the Cornish side of the Tamar. After the charter of Earl Edmund, the Cornish stannators met (apparently) at Truro; those of Devon at Crockern Tor on Dartmoor. An officer was appointed by the duke of Cornwall or the Crown, who was lord warden of the stannaries The last Cornish stannary parliament was held at Truro in 1752. A committee was appointed to report on the subject, and an act of parliament was (1836) passed, suppressing the law courts of the stewards of the different stannaries and giving to the vice-warden their jurisdiction. By the Stannaries Act 1855 the respective parliaments or stannaries courts of Cornwall and Devon were consolidated. By the Stannaries Courts Abolition Act 1896 the jurisdiction was transferred to the county courts. The most important customs were: (*a*) "free tinners" had the right to work upon rendering the "toll-tin," usually one-fifteenth of the produce, to the owner or lord of the soil; (*b*) the right of "tin-bounding," that is, the right of bounding waste lands, subject to tin-toll.

See G. R. Lewis, *The Stannaries* (Boston and New York, 1908); W. S. Lewis, *West of England Tin Mining*, with bibliography (Exeter, 1923); A. K. Hamilton Jenkin, *The Cornish Miner* (1927).

STANNITE, a rare mineral consisting of tin, copper and iron sulphide (a sulpho-stannate, Cu_2FeSnS_4), containing, when pure, tin 27·5, copper 29·5%. It has a metallic lustre, and, when pure, is iron-black in colour; more often, however, it is bronze-yellow, owing to tarnish or to the presence of intimately admixed chalcopyrite: for this reason it is known to miners as "bell-metal-ore" or as "tin pyrites." The hardness is 3·5 and the specific gravity 4 45. It usually occurs as granular to compact masses, rarely as crystals. Minute crystals from Bolivia have been shown to be tetragonal and hemihedral, like chalcopyrite; and to be invariably twinned, giving rise to pseudocubic forms The mineral has been found in a number of Cornish tin mines, and was formerly worked to a limited extent as an ore. At Zinnwald in Bohemia it occurs with blende and galena, and in Bolivia with silver ores. (L. J. S.)

STANTHORPE, a town in the S.E of Queensland, Australia, 198 miles by rail south-west of Brisbane. It stands at an altitude of 2,650 ft. on a N W. spur of the New England Plateau (*see* NEW SOUTH WALES) in the midst of delightful scenery and in a bracing climate (Av. ann. temps.: 80°–35° F, with winter frosts; av ann. rainfall 30·5 in.). Stanthorpe, which is situated on the main interstate line (Brisbane-Sydney), is a noted summer and tourist resort (Pop, including district: *c.* 7,000).

STANTON, EDWIN McMASTERS (1814–1869), American statesman, was born at Steubenville, O, on Dec 19, 1814. He attended Kenyon college at Gambier, O., and was admitted to the bar in 1836. In 1847 he removed to Pittsburgh, Pa As counsel for the State, he invoked successfully the aid of the Federal Government in preventing the construction of a bridge over the Ohio river at Wheeling, Va., (now West Virginia)—on the ground that the structure would interfere with the navigation of that stream by citizens of Pennsylvania. He removed to Washington in 1856. In 1858 he was sent to California by the United States attorney general as special Federal agent for the settlement of land claims. Before the Civil War, Stanton was a Democrat, opposed to slavery, but a firm defender of the constitutional rights of the slaveholders, and was a bitter opponent of Lincoln, whose party he then hated and distrusted. In the reorganization of President Buchanan's cabinet in 1860 Stanton became attorney general, and he did what he could to strengthen the weak policy of the President. Although he had often violently denounced President Lincoln, the latter thought he saw in Stanton a good war minister, and in January, 1862, invited him into his cabinet. Stanton was often harsh, and his peremptory manner was the cause of friction with the generals, an instance being his controversy with Gen. Sherman over the terms of surrender granted to J. E. Johnston's army. But he removed a horde of

fraudulent contractors, kept the armies in the field well equipped and infused energy into procrastinating generals. Not the least of his achievements was the peaceable disbandment of 800,000 soldiers at the end of the war.

Remaining in the cabinet of President Andrew Johnson, Stanton exerted all his energies toward thwarting the policies of that executive, especially those related to the reconstruction of the Southern States. He expressed disapproval of the Tenure of Office Act, making the consent of the Senate necessary for the removal of civil officers, and drafted the supplementary act on reconstruction, passed over the President's veto on July 19, 1867. Stanton was finally asked to resign, and on his refusal to do so the President suspended him (Aug. 12) from office and appointed Gen. Grant (who had disapproved of the secretary's removal) secretary *ad interim.* When the Senate, however, under the terms of the Tenure of Office Act, refused (Jan. 13, 1868) to concur in the suspension, Grant left the office and Stanton returned to his duties. On Feb. 21, 1868, Johnson appointed Gen. Lorenzo Thomas secretary of war *ad interim,* and ordered Stanton to vacate, but on the same day the Senate upheld Stanton, and by way of reply the secretary made oath to a complaint against Thomas for violating the Tenure of Office Act, and invoked military protection from Gen. Grant, while Congress came to Stanton's rescue by impeaching the President, the principal article of impeachment being that based on the removal of Stanton (*see* JOHNSON, ANDREW). When the impeachment proceedings failed (May 26) Stanton resigned and returned to the practice of law. Stanton had a violent temper and a sharp tongue, but he was courageous, energetic, thoroughly honest and a genuine patriot. He died in Washington on Dec. 24, 1869.

See George C. Gorham, *Life and Public Services of Edwin M. Stanton* (Boston, 1899) and Frank A. Flower, *Edwin McMasters Stanton: The Autocrat of Rebellion, Emancipation, and Reconstruction* (1905).

STANTON, ELIZABETH CADY (1815–1902), American leader in the woman's rights movement, was born in Johnstown, N.Y., on Nov. 12, 1815, the daughter of Judge Daniel Cady. In her father's law office she learned of the discriminating laws under which women lived, and many tragic cases observed there determined her in the ambition to equalize the rights of her sex. She did much by the circulation of petitions to secure the passage in New York in 1848 of a law giving a married woman property rights. In the same year, on June 19 and 20, in Seneca Falls, was held, chiefly under the leadership of Mrs. Stanton and Mrs. Lucretia Mott, the first woman's rights convention in the United States. For this convention Mrs. Stanton had drawn up her famous woman's bill of rights setting forth the inferior and unjust position of women in State, church, law and society, and resolutions demanding redress, which were adopted. All of these demands have since been extensively granted. One of them, introduced without Mrs. Mott's approval, was a resolution in favour of equal suffrage for women, which, when approved, became the first organized demand in the United States by women for the ballot. In 1850 she became associated with Susan B. Anthony and for 40 years the two worked together, each admirably supplementing the other, Mrs. Stanton writing, Miss Anthony managing affairs. In 1867–70 they co-operated in editing *The Revolution,* a women's rights newspaper. She was president of the National Woman Suffrage Association from 1865 to 1893. With Miss Anthony and Mathilda Gage she wrote *The History of Woman Suffrage* (4 vol., 1887–1902). She died in New York city on Oct. 2, 1902.

See T. Stanton and H. S. Blatch, ed., *Elizabeth Cady Stanton as Revealed in Her Letters, Diary and Reminiscences* (1922).

STANYHURST, RICHARD (1547–1618), English translator of Virgil, was born in Dublin in 1547. At University College, Oxford, he met Edmund Campion. After studying law, he went to Spain, ostensibly as a physician, but really to keep Philip II. in touch with the Catholic interest in England. In 1602 he took holy orders, and died at Brussels in 1618. He translated *The First Foure Bookes of Virgil his Aeneis* (Leiden, 1582), to prove Gabriel Harvey's theory that classical prosody could be applied to English poetry. The translation is a jargon arranged in so-called hexameters.

A reprint in 1583 by Henry Bynneman forms the basis of J. Maidment's edition (Edinburgh, 1836), and of Professor E. Arber's reprint (1880), which contains an excellent introduction. Stanyhurst's Latin works include *De rebus in Hibernia gestis* (Antwerp, 1584) and a life of St. Patrick (1587).

STAPLE, originally a prop or support; in current usage a U-shaped piece of metal, generally galvanized or wrought iron, in wire form with sharpened points, and used as a fastener by driving into wood; also the chief or ordinary bulk articles of trade. In England the term was applied to towns which were appointed by the king to be the merchants of the staple. These merchants had a monopoly in the staple commodities, viz., wool, wool fells, leather, tin and lead, and were the origin of all English trading companies. (*See* also NAIL MANUFACTURE.)

See C. Gross, *Gild Merchants;* W. Cunningham, *Growth of English Industry and Commerce.*

STAR, the general term for the luminous bodies seen in the sky, but more especially applied to the "fixed stars," which maintain practically the same relative positions in the sky and form constant patterns or constellations. The planets or "wandering stars" are accordingly excluded (*see* ASTRONOMY).

Unlike the planets which shine by reflected light from the sun, the stars are self-luminous. They are bodies of the same nature as the sun; and the only reason why the sun appears so much more brilliant is that it is comparatively close to us. The following figures speak for themselves: Distance of sun—92,900,000 miles; distance of nearest star—25,500,000,000,000 miles. Each star is a fiery globe enormously larger than the earth. Some stars may have planets but we cannot yet detect such planets if they exist. Moreover, theoretical researches warn us against speculation; the system of planets round the sun may be something of a freak.

Although we have been able to learn indirectly the actual dimensions of many of the stars, their size is not revealed by telescopic observation. In the largest telescope a star remains a point of light, and there is no possibility of observing surface markings such as we see on the sun. One unexpected feature, however, is seen directly a telescope is used; a considerable number of the stars which appear single to the naked eye, are seen in the telescope to consist of two stars. The occurrence of close pairs of stars is far too frequent to be due to chance; and, indeed, in some cases the two components have been observed to be revolving round one another. We have to recognize that although single stars like the sun are in the majority, evolution has very frequently taken another course and furnished pairs of luminous globes.

It can be recognized with the naked eye that the stars differ in colour. The colour is not very vivid; but, for example, if the reader is familiar with the constellation Orion, he will easily see that the brighter of the two shoulder stars (Betelgeuse) has a reddish tinge in contrast to all the other bright stars in the constellation, which are white. The quality of the light (crudely indicated by the colour, and in a more detailed way by examination with a spectroscope) is a clue to the surface temperature of the star. As we should expect, the "white-hot" stars are the hottest, and the "red-hot" stars the coolest. Another fact which can be verified with the naked eye, though it requires patient and systematic watching, is that some of the stars give an inconstant light which varies periodically in the course of a few days or months. There are several different kinds of variable stars described below; in one class the variation is a genuine physical change, the star swelling and contracting with regular pulsations.

The Stellar Universe.—Thus the statement that the stars are "suns," whilst giving a correct general idea of their nature, must be amplified to cover a wide variety of objects with many individual characters. They differ greatly in physical condition. Betelgeuse (above-mentioned) is an example of one extreme; it is a gigantic globe so large that the whole orbit of the earth could be put inside it, but so tenuous that its density is less than $\frac{1}{1000}$ that of air—many a so-called vacuum is not more exhausted than this. An example of the other extreme is the companion of Sirius (*see* SIRIUS), which is compressed to a density far exceeding anything known on earth, and is in size not so large as the planet Uranus. Besides the study of the stars as individual

units we have to consider their organization as a system. The principal indication of this organization is found in their motions. Although we often call them *fixed stars,* they are moving rapidly with speeds of the order 10 to 100 m. a second. Notwithstanding their great distance, the resulting changes of position in the sky can be determined by refined measurement; it is the exception for a bright star to have a motion too small to be detected in, say, 20 years. Further evidence of organization is afforded by the distribution of the stars in the sky. They are crowded towards one special plane, viz, that marked out by the Milky Way, or Galaxy, a band of diffuse light stretching all round the sky which, under telescopic examination, is resolved into millions of faint stars. In general, in speaking of the stars we refer to this galactic system or universe, but it is believed that the spiral nebulae, of which there are a great number, are island universes coequal with our galactic system. In some of these nebulae individual stars can be detected by aid of the largest telescopes.

We find ourselves then in a galaxy which is just one amid perhaps a million spiral nebulae. The nearest of the other systems is so remote that light takes nearly a million years to traverse the void which separates us from it. The number of stars in our own galaxy is estimated at some 3,000 millions—a prodigious number, but we might, perhaps, recall that it amounts to less than two stars apiece for the human inhabitants of the earth. To one of the less distinguished stars of this host is attached the earth, which is our home. The evolutionary process which has swept across this system, condensing stars out of the primitive mist, has occupied a time which must probably be reckoned in millions of millions of years. From this orgy of inconceivable numbers we may, perhaps, glean an impression of man's place in the material universe The space and the time which belong to him are as nothing in the far extent and the untold ages of inorganic nature. Is terrestrial man the one and final purpose of it all? Nothing in astronomy has appealed more to the imagination than the conception that each of the myriad points of light in the sky may be giving warmth and light to planets like our earth. It would seem a presumption to deny to them inhabitants of the same order of creation as ourselves. Nevertheless, we must not forget the prodigality of Nature If indeed she has no grander aim than to bring forth her favoured child, Man, it would be just like her methods to scatter a million stars whereof but two or three might haply achieve her purpose. Strong reasons have been given by J. H. Jeans for regarding our solar system as a very unusual development Although probably not unique, the formation of a system of planets is not the normal course of evolution of a star It only happens when, at a critical stage of development, disruption is caused by the accidental approach of another star—a fortune which, perhaps, not one star in a hundred millions would be likely to undergo This theory is subject to much uncertainty; but it is at least a useful corrective to the view, often too facilely accepted, which assumes an almost infinite plurality of living worlds.

History of the Study of Stars.—In the older books on astronomy most of the space is devoted to the bodies of the solar system (sun, moon, planets, comets); the little that was known of the stars could be compressed into two or three chapters at the end. It is natural that our first acquired knowledge should relate chiefly to the bodies that are nearest to us. Much labour was devoted to observing the stars, but that was largely because they had to serve as graduation marks in the sky against which the movements of the planets and comets could be recorded Of late the *centrifugal* march of astronomical knowledge has been very remarkable, and the study of the stars is now the largest field of astronomical research The following may be selected as the chief landmarks in this progress:

1. The first variable star (Mira Ceti) was discovered by Fabricius in 1596.

2 The first double star (Mizar) was discovered by Jean Baptiste Riccioli in 1650

3. Edmund Halley first detected the proper motions of stars (Arcturus, Aldebaran, Sirius) in 1718.

4. Sir William Herschel may be regarded as the pioneer of studies of the sidereal system. He discovered the solar motion (motion of the sun through the system of the stars) in 1783. By his famous counts of stars (star-gauges) he established the flattened form of the stellar universe. In 1803 he was able to announce, from his measures of double stars made during the previous 25 years, the confirmation of the theory (urged by Christian Mayer in 1779) that the components revolve round one another.

5. In 1839 distances of the two stars 61 Cygni and α Centauri were found by measurement of parallax by F. W. Bessel and T. Henderson, respectively. This gave the first definite idea of the scale of the stellar system

6. In 1862 William Huggins applied the spectroscope to the stars and identified many familiar terrestrial elements as present in their atmospheres. The classification of stars according to their spectra was instituted by Angelo Secchi shortly afterwards.

7. Photography of the stars was developed between 1882 and 1887, the international photographic chart of the heavens and catalogue (not yet completed) being planned in the latter year.

8. Measurement of the velocities of stars in the line of sight by means of the spectroscope was developed very slowly in the latter part of the 19th century. The early measurements were entirely untrustworthy, and it is difficult to say when this powerful aid to stellar research properly started. Good results were obtained by H. C Vogel and J. Scheiner in 1888–91. A great development of this branch of work was brought about by W. W. Campbell from 1897 onwards. The first spectroscopic binary star (Mizar) was found by E. C. Pickering in 1889.

9 J. C. Kapteyn discovered, in 1904, that, at least in our local system, the stars are moving in two main streams This gave great stimulation to statistical studies of the sidereal universe

10 The distinction between giant and dwarf stars made manifest by the researches of E Hertzsprung and H N Russell began to be generally accepted about 1913

11 The first direct determination of the angular diameter of a star, *i e*, the apparent size of its disc, was made by F G Pease and J. A Anderson in 1920, using an interferometer designed by A. A Michelson.

12 The physical theory of ionization was applied by M. N. Saha to the interpretation of spectral features of the stars in 1920 This led to a branch of research which has had most extensive developments.

The Twinkling of Stars.—Before entering on a fuller account of this progress we must refer to a question which is often put. Why do the stars twinkle? If we trace the beam of light, roughly $\frac{1}{10}$in in diameter, which fills the eye-pupil back towards the star, it has passed through some miles of terrestrial atmosphere. Differences of density due to slight inequalities of temperature will cause continual changes of refraction at one point or another on the path, giving rise to a general unsteadiness More important still is the "interference of light" The irregularity of density may be such that the light at opposite edges of the narrow beam has traversed different effective thicknesses of air, so that the corresponding waves are delayed by different amounts. If the delay amounts to half a wave-length the waves will arrive crest-on-trough, and, instead of summing up to give a bright star-image, they will cancel one another. Thus the image pops in and out as the changes of atmospheric density succeed one another. The condition for cancelling is different for light of different colours (corresponding to different wave-lengths), consequently the star sparkles with different colours. To understand why this does not happen to the light of the planets we must recall that the disc of the planet, unlike the star-disc, subtends a considerable angle at the eye The diameter of Saturn, for example, is normally about 20 seconds of arc, which means that at the height of a mile the rays which reach the eye fill an area 6 in. in diameter. This gives plenty of scope for the variations of the individual beams ($\frac{1}{10}$ in. in diameter) to average out, and consequently they combine to give a fairly steady brightness. Interference or cancelling of waves occurs between waves reaching different parts of the pupil, but not between waves starting from different parts of the disc of the planet or star; thus twinkling depends on the ratio between the angular sizes of the celestial object and of the eye-

pupil as viewed from an average height in the earth's atmosphere.

NUMBER AND MAGNITUDE OF THE STARS

On a clear dark night the stars seem to be innumerable in multitude, but in reality the number in the whole sky visible to the unaided eye is about 6,000. A small telescope greatly multiplies the number, and the largest instruments (aided by long photographic exposures) would reveal some hundreds of millions. The brightness is expressed by "magnitudes," the progressively fainter stars being of progressively greater magnitude. A star is defined to be one magnitude higher than another if its light is fainter in the ratio 2·512; this ratio is adopted so that a difference of five magnitudes may correspond to a light-ratio of 1:100. The faintest stars visible to the naked eye on clear nights are about the 6th magnitude. The brightest star, Sirius, has magnitude −1·6 *i.e.*, 7·6 magnitudes brighter, or just over 1,000 times more luminous, than the faintest naked-eye stars. Classified on the same scale, the sun's magnitude is −26·7. It is possible with the largest instruments to reach stars of about the 21st magnitude. It gives some idea of the light-grasp which has been attained if we notice that the interval from the sun to Sirius (25 magnitudes) is comparable with the interval from Sirius to the faintest stars observed (23 magnitudes).

If the stars were distributed uniformly through infinite space and their light suffered no absorption, each magnitude would comprise 3·98 times as many stars as the preceding magnitude (the number 3·98 is the $\frac{3}{2}$ power of the light-ratio 2·512). This theoretical star-ratio is not realized in the actual distribution. It may be taken as a rough rule that an increase of one magnitude multiplies the number of stars about threefold for the brighter stars, but the factor falls off rapidly for the faintest stars. This is an indication that the density of distribution of the stars in space falls off at great distances—that we are in the midst of a limited cluster or star-cloud. The following table gives the results of F. H. Seares and P. J. van Rhijn (1925) for the number of stars in the sky brighter than the indicated visual magnitude:

Magnitude	Number of stars	Magnitude	Number of stars	Magnitude	Number of stars
4·0	530	9·0	117,000	14·0	13,800,000
5·0	1,620	10·0	324,000	15·0	32,000,000
6·0	4,850	11·0	870,000	16·0	71,000,000
7·0	14,300	12·0	2,270,000	17·0	150,000,000
8·0	41,000	13·0	5,700,000	18·0	296,000,000
				19·0	560,000,000

Up to a certain point each magnitude contributes more star light than the preceding, the increased number of stars in the magnitude-interval more than counterbalancing their individual faintness. The maximum is reached between the 11th and 12th magnitudes, the $1\frac{1}{2}$ million stars in this interval giving a combined light equivalent to 84 stars of magnitude 1·0. Beyond this the contribution falls off. All the stars together give as much light as 1,100 stars of magnitude 1·0—a result which has been checked closely by direct measurement of the general light of the sky.

The above figures relate to the whole sky. Interesting results are found when we compare the density of distribution of the stars in different parts of the sky, particularly when we compare regions in the plane of the Milky Way with those near its poles. The galactic concentration (ratio of the number of stars in equal areas in the galactic plane and at the galactic pole) increases from 3·4:1 for mag. 4 to 4·3:1 for mag. 10, and to 21:1 for mag. 18. These results refer to photographic magnitude, no sufficiently extensive counts for visual magnitude being available. The great excess of stars in the galactic regions is not wholly or even mainly due to the star-clouds of the Milky Way itself; the star-density increases steadily from the poles to the galactic plane, and the concentration is conspicuous before any part of the Milky Way is reached. This phenomenon was discovered by Sir William Herschel and the modern results are in good agreement with the star-counts made by him and by his son, Sir John Herschel. It seems certain that the stars surveyed by us (the "local system") form an aggregation strongly flattened in shape like a bun or lens. Probably this is one of many star-clouds lying in the galactic plane, the whole being coiled into a spiral nebula. From other indications it appears that we are very far from the centre of the spiral, which is found to lie in the direction of the constellation Sagittarius. The sun cannot be said to occupy a privileged position among the stars; it is nearly central in the star-cloud to which it belongs, but this star cloud is an outlier of the main galactic system—which in turn is only one among thousands of its kind.

Nomenclature of the Stars.—The brighter stars are designated by a Greek letter followed by the name of the constellation, according to a system introduced by J. Bayer in his star maps in 1603. The letters are assigned roughly in order of brightness, but for stars of nearly equal brightness the order is that of position in the constellation usually beginning at the head of the object figured. Alternatively, a system of numbers (followed by the constellation name) introduced by Flamsteed can be employed; this covers many stars which have no Bayer letter. Flamsteed's numbers were assigned in order of right ascension. For example, 27 Geminorum = ϵ Geminorum; 32 Leonis = αLeonis = Regulus. A number of ancient names of conspicuous stars survive; many of these are of Arabic origin. The following list gives those which are familiar to the modern astronomer, together with their Bayer equivalents and their visual magnitudes:

Name	Bayer equivalent	Visual magnitude
Achernar	α Eridani	0·60
Alcor	γ Ursae Majoris	4·0
Alcyone	η Tauri	2·96
Aldebaran	α Tauri	1·06
Algenib	α Pegasi	2·87
Algol	β Persei	Var.
Altair	α Aquilae	0·89
Antares	α Scorpii	1·22
Arcturus	α Boötis	0·24
Bellatrix	γ Orionis	1·70
Betelgeuse	α Orionis	Var.
Canopus	α Carinae	−0·86
Capella	α Aurigae	0·21
Castor	α Geminorum	1·58
Cor Caroli	α Can. Venaticorum	2·90
Deneb	α Cygni	1·33
Denebola	β Leonis	2·23
Fomalhaut	α Piscis Australis	1·29
Markab	α Pegasi	2·57
Mira	o Ceti	Var.
Mizar	ζ Ursae Majoris	2·40
Polaris	α Ursae Minoris	2·12
Pollux	β Geminorum	1·21
Procyon	α Canis Minoris	0·48
Regulus	α Leonis	1·34
Rigel	β Orionis	0·34
Sirius	α Canis Majoris	−1·58
Spica	α Virginis	1·21
Vega	α Lyrae	0·14

Only 20 stars are ranked as brighter than mag. 1·5. Of these 17 (including the variable Betelgeuse) are named in the above list. The other three are the southern stars, α Centauri (mag. 0·06), β Centauri (0·86), β Crucis (1·50).

Stars not bright enough to have a constellation letter or number are designated by their reference number in some catalogue. Thus we have names like Bradley 1,940, Groombridge 2,230, Boss 3,932, the last reference (Lewis Boss, *Preliminary General Catalogue*), being especially preferred. The most comprehensive source of reference is the *Bonn Durchmusterung* made by Argelander. This work, completed in 1862, lists the places of 324,000 stars between the north pole and 2° S. An extension to 23° S. by Schönfeld adds 133,000 stars. Star charts to be used with the catalogue are published, and there is no difficulty in identifying in the sky a star referred to, for example, as B.D.+13°, 2,966. The *Cordoba Durchmusterung* (C.D.M.) and *Cape Photographic Durchmusterung* (C.P.D.) fulfil a similar function for the rest of the southern sky. For stars fainter than the limits of these surveys an author must describe the identity as best he can.

Double stars are generally designated by the name of the dis-

coverer, with the ordinal number of his discovery, or the number in Burnham's *General Catalogue* may be given. Variable stars are assigned (in order of discovery in the constellation) Roman capital letters from R to Z, or a pair of these letters, *e.g.*, X Cygni, RT Aurigae.

Colour of Stars.—In stellar observation the photographic plate is used quite as commonly as the eye Alongside the visual scale of magnitudes measuring the brightness of the stars as judged by the eye, we have a photographic scale of magnitudes giving the brightness as judged by the effect on ordinary photographic plates. It is well known that blue light has proportionately greater actinic power than red light; consequently a comparison of the magnitudes of a star on the two scales gives a measure of its colour. The difference, photographic minus visual magnitude, is called the *colour-index*. (*See* PHOTOMETRY. *Celestial*)

A classification which runs nearly parallel with classification by colour is afforded by examination of the spectrum of the light. In the Draper classification, now universally adopted, a continuous sequence of types is recognized denoted by the letters O, B, A, F, G, K, M. Intermediate types are indicated by decimal division, *e.g.*, A2 is a type two-tenths of the way between A0 and F0 A cursory examination of the spectrum is sufficient to determine the type, and 225,000 stars have been classified in this way by Miss A J. Cannon (*Harvard Annals*, vols 91–99). The sequence O to M corresponds to progression in colour from blue to red, and progression in temperature from the hottest to the coolest stars The sun is of type G0. The percentages of stars catalogued in these classes are: B, 2; A, 29; F, 9, G, 21; K, 33; M, 6 Type O is rare, not more than 20 stars brighter than mag. 6 25 being known. The letters N, R, S denote other rare types whose relation to the recognized sequence is still uncertain The properties of the stars (distribution, mass, luminosity, motion, variability, etc.) are all closely correlated to the spectral type; so that in nearly all investigations it is necessary to study the different types separately. The terms "early type" and "late type" are still commonly used in accordance with the order in this series, *i.e.*, for the bluer and redder stars respectively. The terms originally had reference to a theory of the progress of stellar evolution which is now entirely discarded

Some progress has been made with the direct measurement of the heat received from the stars, and the corresponding bolometric magnitudes (related to heat intensity in the same way that visual magnitudes are related to light intensity) have been determined. The star-image is focussed on a small disc in which a thermoelectric junction is embedded, and many hundreds of stars are found to give sufficient heat to be measured in this way. The main trouble in these investigations is that the radiant heat over a certain band of wave-lengths is largely absorbed by the water-vapour in our atmosphere, and rather large corrections must be applied on this account The bolometric magnitude may also be inferred from the visual magnitude by applying a correction depending on the spectral type of the star This correction, called the *heat-index*, is analogous to the colour-index, and varies in correspondence with it. Naturally, the red stars are "brighter" bolometrically than visually, because their radiation is of low luminous efficiency. The greatest luminous efficiency is for stars of types F and G, perhaps because the human eye has been developed so as to make the most of sunlight. In still hotter stars there is a falling off of luminous efficiency, the radiation being too far in the violet and ultra-violet to suit the eye.

Absolute Magnitude.—We turn now to consider the real brightness of the stars. How would they compare with the sun in splendour if we could see them at the same distance? To infer the true brightness from the apparent brightness we must first know the distance (for the methods of measuring the distance *see* PARALLAX). An idea of the variety of brightness may be given by considering the seven most conspicuous stars. Sirius gives 28 times the sun's light, but it has a companion only $\frac{1}{360}$ as bright as the sun. Canopus is so remote that its distance cannot be found accurately, but it can scarcely be less than 10,000 times as luminous as the sun. α Centauri consists of two stars, one almost a replica of the sun and the other considerably fainter. Then follow Vega and Arcturus with luminosities 50 and 100 in terms of the sun. Capella consists of two stars, with luminosities 110 and 70, having a faint distant companion of luminosity about 0·01. Rigel is remote, but its distance is more certain than that of Canopus; its luminosity is greater than 10,000.

This shows that there are stars far surpassing the sun in brilliancy; but, naturally, if we pay attention only to the most conspicuous stars we shall form an exaggerated idea of the general order of brilliance. There would be the same difficulty if we extended our survey to all the naked-eye stars; these would include the most luminous stars contained in a very wide region and the feebler stars in a much smaller region It is only by rather elaborate investigations that we can get together a fair sample of the stellar population, in which the luminous stars are not over-represented by forcing themselves on our attention According to the latest discussions the following table gives the relative proportions of stars of different degrees of intrinsic brightness in any volume of space:

Light power	Number	Light power	Number
10,000×sun	1	1 ×sun	200,000
1,000 ,,	90	0·1 ,,	350,000
100 ,,	3,300	0 01 ,,	500,000
10 ,,	42,000	0·001 ,,	600,000

Stars fainter than the sun far outnumber those which are brighter.

At present the faintest known star is one to which attention was drawn by A van Maanen It was picked out from the multitudes of apparently similar stars by its rapid motion across the sky, which indicated that it was likely to be especially near to us It has an absolute visual magnitude 16 5, corresponding to $\frac{1}{50000}$ of the light of the sun. Its catalogue designation is Wolf 359. Other very feeble stars are Proxima Centauri (mag 15 4), van Maanen's star (14 3), Barnard's star (13·3), Groombridge 34 *comes* (13 0). All these are cool red stars and their photographic brightness is about two magnitudes fainter.

At the other end of the scale it is difficult to assign an upper limit to the brightness because the objects suspected of great brilliancy are generally too remote for parallax measurement. In the star clusters, however, we see a group of stars all at practically the same distance, and can therefore measure at once the relative brightness of different classes of objects The star S. Doradus in the Greater Magellanic Cloud is believed to have an absolute magnitude −9(400,000×sun); and other stars in the same cloud are not far short of this. The range in real brightness of the stars is at least 20 magnitudes—very much the same as the range in apparent brightness so far as it is possible to observe it.

Interferometer Measurements.—One of the striking achievements in recent years has been the measurement of the angular diameters of a few favourable stars by means of Michelson's interferometer (*q.v*). As adapted to astronomical work this consisted of a 20 ft. beam carrying two inclined mirrors which could slide along it, and carried on the 100 in. telescope at Mt. Wilson observatory; the light from the movable mirrors fell on two fixed mirrors, and was directed by them on to the great telescope mirror. Virtually the observer was looking simultaneously through two apertures whose separation could be varied up to 20 ft., very much as in a gigantic range-finder. (*See* BINOCULAR INSTRUMENT: *Stereoscope*.) The effect of using two apertures is that the spurious (diffraction) disc of the stellar image is crossed by fine diffraction lines, and the lines become closer as the separation of the apertures is increased. If the object looked at is not a mere point of light, its finite size blurrs the diffraction pattern, and the object of using widely separated apertures is to obtain a diffraction pattern so fine that even the invisible disc of a star is sufficient to blurr it out and make it disappear. Seven stars have been found to have angular diameters exceeding 0·02″ which is about the limit attainable with this instrument; a 50 ft. interferometer was, in 1928, under construction at Mt. Wilson, with which it is hoped to secure more stars, but the great majority must remain beyond the scope of this method. In some ways this application of the interferometer is to be regarded rather

STAR CHART OF NORTH POLAR HEMISPHERE

Most stars visible to the naked eye and north of the celestial equator are shown in this chart. The North Star, Polaris, is shown slightly to the right of the north celestial pole. This star is not exactly true north. At the bottom of the chart is the first magnitude star Betelgeuse in the constellation of Orion. This was the first of the large stars to have its diameter measured. At the left of the north celestial pole is the "Great Bear" with its pointer stars in line with the North Star. In the upper part of the chart is the constellation Hercules toward which the entire solar system is moving at the rate of about 12 miles per second. Owing to the rotation of the earth on its axis, all stars shown in this chart appear to rotate around the north celestial pole in a counter clockwise direction

STAR CHART OF THE SOUTH POLAR HEMISPHERE

Showing all of the principal stars visible to the naked eye found south of the celestial equator. To the left of the south celestial pole in the chart is the Southern Cross (Crux). Below the south celestial pole and slightly to the left is Scorpio which contains the giant red star Antares, which has the greatest diameter of any star that has been measured up to the present time It is visible from practically every point in the inhabited world. To the right of the south celestial pole is Fomalhaut, a first magnitude star in the constellation "The Southern Fish." Sirius, of the constellation "The Big Dog" and the brightest star in the sky, is near the top of the chart All stars shown in chart appear to revolve around the south celestial pole in a counter clockwise direction due to the rotation of the earth on its axis

as a *tour de force* than an important advance of knowledge, because we can always compute approximately the angular diameter from the apparent magnitude and spectral type (which determines the radiating power of the surface) by a simple theory that can scarcely be doubted. Up to the present the observed diameters have been found to be in close accord with the theory. Of special interest, however, are the observations of the variable star, Mira Ceti; here the interferometer measurements indicate variations in the diameter, and seem to confirm the theory, put forward on other grounds, that this type of variability is due to pulsation.

Another application of the interferometer is to measure the separation of double stars in which the components are so close that ordinary visual measurements are impossible. In particular Capella, which is known to be a double by spectroscopic observation, cannot be resolved by any telescope. Nevertheless, by interferometer measurement the orbit has been found just as though it were a visual double. We have the rare opportunity of combining visual and spectroscopic orbital data, and the result is that Capella is one of the best known stars as regards mass, absolute luminosity, etc.

DOUBLE STARS

About the year 1650 Jean Baptiste Riccioli made the first discovery of a double star, viz., Mizar or ζ Ursae Majoris, the middle star in the tail of the Great Bear. Looking at Mizar with the naked eye, we see a fainter star, Alcor, very close to it; it is a fair test of eyesight to separate them. Their separation is however, 11′, and although there is no doubt that Mizar and Alcor have a physical association, since they are found to be moving at just the same rate across the sky, the term double star is only applied in case of much closer proximity. Riccioli's discovery was that Mizar itself consists of two stars separated by 15″ or about $\frac{1}{40}$ of the distance between Mizar and Alcor. This would nowadays be regarded as a wide pair, and many of the most interesting double stars have a separation under 1″. The actual distance between the two components of Mizar is not less than 11 times the distance of Neptune from the sun. The two stars must be attracting one another, but the gravitational control across such a distance is so feeble that they will take more than 3,000 years to complete their orbital revolution. It is, therefore, not surprising that the measures made during the last 150 years fail to indicate definitely any orbital motion; and the only evidence of genuine connection (apart from the improbability of two independent bright stars lying so closely in the same line of sight) is afforded by their common motion across the sky, and common radial velocity.

Similar discoveries followed rapidly. θ Orionis (in the midst of the great nebula) was resolved by Huyghens in 1656; γ Arietis by Hooke in 1664. In the southern hemisphere the duplicity of α Crucis and α Centauri was discovered by Jesuit missionaries in 1685–89. The foundation of systematic measurement and study of double stars is due principally to Sir William Herschel and Wilhelm Struve. The latter, working at Dorpat between 1813 and 1835, formed a catalogue of 3,110 pairs as the result of surveying about 120,000 stars.

The number of recognized visual double stars is now about 15,000, but the number is necessarily somewhat arbitrary since, if too wide limits of separation are admitted, stars which are only in accidental proximity may be included. Among the naked-eye stars, one in nine is a telescopic double. It is certain that the true proportion of binary systems is much greater than this, many being too close to be resolved with the telescope. Thus, taking the nearest known stars (which give the best chance of observing duplicity), eight out of 20 are double.

Catalogues of double stars no doubt contain a number of spurious pairs, *i.e.*, stars which are not actually near one another in space and merely happen to lie in the same line of sight, but considerations of probability show that there will not be many of these. The physical connection is generally shown, as in the case of Mizar, by common proper motion. If spectroscopic determinations of radial velocity have been made these will provide an additional check. The connection implied is evidently the connection of a common origin. The two stars were born from the same nebula; they originally shared in common the velocity of the parent nebula, and they have gone on moving together because they have been subjected to the same influences ever since. In most of them the gravitational tie is too weak to resist any differential disturbance, *e.g.*, another star passing between the pair. The fact that so many of these wide doubles survive teaches us that chance approaches of stars to one another must be very rare.

Of greater interest are those double stars close enough together to show the effects of their mutual gravitation. There are about 120 double stars for which it has been possible to work out definite orbits. In about 700 more there is a rough indication of orbital motion, but the arc described since observation commenced is too short to determine the orbit satisfactorily. The shortest periods are 5·7 years (δ Equulei) and 6·9 years (13 Ceti); about 60 pairs have periods of under 100 years. It is natural to enquire whether the planes of the orbits tend to lie in any particular direction—parallel to the galactic plane, for example. A curious difficulty arises in this investigation. If the reader has watched the revolution of a cup-anemometer (or of a garden-sprinkler) he will probably recall that the direction of revolution appears obvious and unmistakable, but after blinking the eyes the revolution seems just as unmistakably in the opposite direction and in a different plane. For the same reason we always find two planes of rotation of the double star, either of which may be the true one. We can only adopt both planes, and investigate as best we can the resulting mass of data, half of which is correct and half spurious. So far as can be ascertained the planes of double star orbits are quite at random.

The two dog-stars, Sirius and Procyon, are double stars of exceptional historic interest. Being conspicuous stars they were well observed a hundred years ago and used as fundamental reference stars for determining time, etc. It was found that they were moving irregularly—not with uniform proper motion like other stars. It was evident that each was being disturbed by the gravitation of a massive body in its neighbourhood, although the companions were invisible. The theory was given by Bessel in 1844, and orbits were computed from the observations, the periods of revolution being 50 and 39 years respectively. The disturbing stars, whose existence was thus convincingly demonstrated, have since been seen. The companion of Sirius was observed by Alvan Clarke in 1862, and is a comparatively easy object for modern telescopes; the companion of Procyon, which is more difficult, was observed by Schaeberle in 1896. They are faint stars, respectively 10 and 13 magnitudes fainter than their primaries. Nevertheless, they must be massive bodies to exert so large a pull on their brilliant neighbours.

Masses of Stars.—The orbital motion of double stars conforms to the law of gravitation. It gives evidence that gravitation is universal in the stellar system. The study of binary systems performs a unique service in the general advance of our knowledge of the stars since it is through it that we arrive at knowledge of the masses of the stars. By the law of gravitation the extent to which a body disturbs the motion of other bodies is proportional to its mass. It is when we find bodies in close proximity that we obtain a chance to observe the disturbance, and so obtain a measure of the mass. It is good fortune for the astronomer that the course of evolution has been such as to provide pairs of stars close enough together; otherwise we should probably still be in total ignorance as to the masses of stars, except in so far as the sun's known mass might be assumed to be typical.

If M_1, M_2 are the masses of the two components, a the mean distance between them (strictly the semi-axis major of their relative orbit), and P the period of revolution, Kepler's laws give

$$k(M_1+M_2)=a^3/P^2$$

where k is a universal constant. Let us measure the mass in terms of the sun's mass as unit, the period in years, and a in astronomical units, *i.e.*, in terms of the earth's distance from the sun. Applying the equation to the earth's motion round the sun (the earth's mass M_2 being negligible) we see that for these units $k=1$. Now apply the equation to Sirius. The mean distance of the two

components is 7·55 seconds of arc. To convert this into linear measure we must know the parallax of Sirius, 0·37 second. This means that one astronomical unit seen at the distance of Sirius would appear to extend 0·37 second, hence 7·55 seconds corresponds to 20·4 astronomical units, determining a The period P is 49 years. Hence

$$a^3/P^2=(20\cdot 4)^3/(49)^2=3\cdot 5=M_1+M_2$$

We learn, therefore, that the combined mass of the two components is three and one-half times that of the sun. If it is preferred to express the mass in tons, this can be done since the sun's mass is 1,980,000,000,000,000,000,000,000,000 tons

To find the masses of the two stars separately we must determine their absolute orbits about their common centre of gravity instead of the relative orbit considered above This means measuring the motions of the components with respect to surrounding stars instead of with respect to one another. It is found that the bright star has the greater share of the mass, nearly in the ratio 3:1.

From the visual double stars, together with the spectroscopic binaries (described below), an idea of the masses of stars in general has been obtained Comparatively few determinations reach high accuracy, because a rather accurate parallax is required which is not generally forthcoming The first thing that strikes us is the wonderful uniformity of mass By far the majority of the determinations give between one-third and three times the sun's mass, which seems a very small range when compared with the great differences of luminosity Another result brought out is the close relation of mass to luminosity, the brighter stars being the more massive It is probable that (excluding a peculiar class of stars known as *white dwarfs*) the luminosity depends almost entirely on the mass; it makes little difference whether the star is in a dense or in a diffuse state. The theory of this relation will be explained later. Having checked it by the masses determined for double stars, we can use it to find the masses of other stars whose absolute brightness is known.

We naturally select the most conspicuous stars for special investigation, and as a result we tend to pick out exceptionally high masses. Among the spectroscopic binaries some very high masses have been found, which, however, are believed to be exceptional For one binary of Type O discovered by J. S. Plaskett the components have masses greater than 87 and 73 in terms of the sun (Only a lower limit can be stated) Another O type binary has masses 36 and 34 The eclipsing variable V Puppis has two components each of mass 19·2. There is at present no evidence of any stellar masses below one-sixth of the sun's mass

From the close uniformity of stellar masses it follows that the stars of gigantic volume like Betelgeuse must be of extremely low density. Assuming that the mass of Betelgeuse is something less than 100 times the sun's mass, in order to fill a volume 50 million times greater than the sun, the density must be less than $\frac{1}{100}$ that of air.

Spectroscopic Binaries.—When a source of light is approaching us, the lines in its spectrum appear displaced towards the violet end; when receding, the displacement is towards the red end By means of this "Doppler effect" (*see* LIGHT) the velocity of a star in the line of sight can be measured In examining the stars with a spectroscope we sometimes turn the instrument on to what is telescopically a single point of light, but is actually a double star with components too close to be separated Since the two components have different velocities towards or away from us their spectra will not be exactly superposed and every spectral line will appear double The first example of this was found by E C. Pickering in 1889 This was the star Mizar already mentioned as the first visual double star to be discovered. The two components seen in the telescope take at least 3,000 years to perform their revolution; but the doubling of the spectral lines of the brighter component shows that it is itself a double star with a revolution period of 104 days. If a star showing a doubled spectrum is watched for some time it is seen that the doubled lines close up and then cross one another This is in accordance with the theory of orbital motion, for the two components must approach us and recede from us alternately in the course of a revolution.

It is only when the two components are of nearly equal brightness that this doubling of the spectral lines can be observed. A difference of about two magnitudes is sufficient to render the fainter spectrum invisible. In the majority of spectroscopic binaries only the brighter spectrum is observed, and the binary character is inferred from the periodic approach and recession of the source emitting it. The argument is that the changing displacement of the spectral lines shows that the source of light is describing an orbit; there must be some mass for it to revolve around; and therefore a fainter component must exist although invisible. Rather more than a thousand spectroscopic binaries have been discovered, and definite orbits have been computed for about 250 of these. The spectroscope can only measure velocity in the line of sight, and many binaries must escape detection through having their orbits nearly perpendicular to the line of sight.

Spectroscopic binaries afford valuable additional information as to the masses of stars, but of a statistical rather than of an individual kind. When one component only is observed, all that can be deduced is a rather complicated function of the masses and the unknown inclination of the orbit; but when both spectra are observed, a minimum mass of each component can be found. This minimum mass has to be multiplied by $\operatorname{cosec}^3 i$ (i=inclination of orbit plane to the sky plane) which is unknown unless the star can also be observed visually or is an eclipsing variable, but in researches on the average mass of any class of stars a suitable mean value of this factor may be used

In rare cases the same system may be observed as a visual and a spectroscopic binary; but in general only the close pairs with periods less than a year are detected spectroscopically, and wide pairs with periods of many years or centuries are detected visually Many intermediate pairs must escape both methods of discovery The first star to be observed by both methods was α Centauri. The results have a special interest because they afford a determination of the star's distance entirely independent of the ordinary method of parallax measurement. The visual observations determine the angular size of the orbit; the spectroscopic observations determine the same quantity in kilometres; so that we have only to compute the distance at which the given length subtends the given angle The result for α Centauri satisfactorily checked the ordinary trigonometric determination of its distance

Multiple systems containing more than two components are not uncommon. We have already noticed the system of Mizar The star Castor is an easy visual double, both components of which are spectroscopic binaries. These systems all appear to be built by successive subdivisions of one mass into two, and it is clear that after such a fission a long period of evolution and condensation must elapse before either of the resulting masses is ready to divide again An important question is whether the widely-separated pairs were originally formed with their present separation or whether the distance has increased in the course of time It is difficult to resist the impression that the components gradually recede from one another, especially as the statistics show markedly that the stars supposed to be oldest in evolution form the widest pairs. Two causes are acting which will tend to increase the initial separation to some extent, viz, the mutual tidal forces and the loss of mass of the stars by radiation; but neither can produce a large effect. The cumulative effect of perturbations by casual approaches of other stars would in the long run, drive the components further apart; this process, however, is too slow to produce much effect, even in the long periods of stellar evolution. The general problem of the formation of double stars is discussed in the article COSMOGONY.

VARIABLE STARS

There are three main classes of variable stars: (1) eclipsing variables, (2) Cepheid variables, (3) long period variables. In a sense the sun is a variable star, since the changes of its surface

condition which follow the sunspot cycle of $11\frac{1}{2}$ years must involve some small variation in the rate of emission of light and heat (*see* SUN); but this is not analogous to any of the recognized forms of stellar variability. Novae or "new stars" might also be counted technically as variables; it is, however, no longer believed that they have anything in common with the ordinary types of variables, and we shall not include them here. (*See* NOVA.)

Eclipsing Variables.—In this type of variation there is no physical change in the star. It emits light steadily all the time, but it is occulted at times by another body passing in front of it. The present explanation dates from 1782, when John Goodricke, having discovered the regular period of fluctuation ($2^d\ 20^h\ 49^m$) of the variable star Algol, suggested that the periodic dimming was caused by a dark body revolving round it and eclipsing it once a revolution. Knowing, as we now do, that there are multitudes of close binary systems, it is only to be expected that we should sometimes observe an eclipse of one component by the other. Each system will provide regularly recurring eclipses for observers situated sufficiently near the plane of the orbit; the eclipsing variables are therefore ordinary binaries whose orbits we happen to be viewing nearly edge on. For Algol and many other variables of this class it has been verified that the object is a binary system, and that the decline of light occurs when the principal star is in the part of its orbit most remote from us, which is the time when the second component would intervene.

It is not necessary to assume that the intervening object is a dark body. Even if the system consisted of two equal stars a total eclipse of one by the other would halve the light received. In most systems that have been studied, one component is considerably brighter than the other, but the light of the second component is quite recognizable. Half a period after the main eclipse, when the faint star occults the brighter, a secondary eclipse is observed owing to the bright star occulting the fainter. There is, of course, a considerable period when no eclipse is occurring and the system shines steadily with its maximum light. (By this feature eclipsing variables are easily distinguished from all other types.) The steadiness in these intervals is, however, only approximate, and is complicated by two phenomena of singular interest:

(1) *Reflection Effect.*—Systems in which the two stars are very close together have the best chance of showing eclipses, since the orbit does not then need to be so accurately orientated with respect to our terrestrial post of observation. The closeness of some of the best-known eclipsing variables is remarkable, the components being separated by no more than their own diameter. Each is therefore strongly illuminated by the other, and the hemisphere turned towards the companion becomes heated and shines more brightly than the other hemisphere. For the fainter star in particular, the disparity in brightness of the two hemispheres is considerable, and as it moves round its orbit it exhibits variations of brightness analogous to the phases of the moon. Owing to this reflection effect, the end of the principal eclipse is followed by a gradual brightening, which continues until the dip representing the secondary eclipse begins.

(2) *Ellipsoidal Effect.*—Owing to their close proximity the two stars are distorted, being elongated towards one another. Thus, in addition to the variation due to eclipses and reflection, there will be a variation depending on the aspect of these elongated objects. Their apparent sections will be smallest when we see them end-on near the time of the eclipses; half-way between eclipses we see the prolate spheroids broadside-on and correspondingly brighter.

We may hope ultimately to learn much as to the physical state of the stars from these two effects; but, unfortunately, they are only just within our range of detection, and it is difficult to obtain accurate measurements of their amount. Meanwhile, an examination of the light-curve during the eclipses teaches us much about the dimensions of the system. The method of analysing the light-curves was developed by H. N. Russell and H. Shapley; for an example of the results obtainable *see* ALGOL. As a rule the fainter component is found to have the larger diameter although it has the smaller mass; *i.e.*, the companion is one of the giant diffuse stars of fairly low density and surface temperature. The eclipses are usually partial, but are in a few stars total or annular. The number of eclipsing variables known at present is about 200.

Cepheid Variables.—Like the preceding class the Cepheid variables have short periods seldom exceeding 20 days, but the cause of the variation is entirely different. A very significant fact is that the colour of the light (or the spectrum) is different at maximum and minimum light, showing that the star undergoes an actual physical change. The surface temperature is much higher at maximum than at minimum, and, in fact, the changes of brightness may be ascribed to the changes of temperature. It is probable that the Cepheid variable is a pulsating star—a globe which swells and contracts with a regular period. Leaving aside the question as to how the star comes to be in this oscillating state, the pulsation theory agrees with the main phenomena. The alternate compression and rarefaction naturally produces the changes of temperature; moreover, the approach and recession, as the part of the surface presented towards us heaves up and down, is observed and measured spectroscopically. The most striking confirmation is the agreement of the theoretical period of such a pulsation with the observed period. The natural free period of a pulsation of a spherical mass of gas should vary approximately as the inverse square root of the density, and the observations show that the Cepheids closely follow this law; moreover, the absolute value of the period can be calculated (with a small margin of uncertainty due to our ignorance of the chemical constitution of the star's interior) and the observed period is found to agree. On the other hand, no satisfactory theoretical explanation has yet been given of the phase-relation between the velocity-curve and light-curve. The mathematical theory of a pulsating star seems to show that maximum brightness must occur at the moment of greatest compression, whereas in all the more typical Cepheids it is found to occur a quarter-period later.

The study of Cepheid variables is likely to lead to results of the greatest importance, since they give the opportunity of observing stellar matter in motion, thereby extending the information obtainable from the ordinary static stars. They are important also for another reason. Practically all our knowledge of the distances and dimensions of the more remote objects of the sidereal universes has grown up from a study of Cepheids. In 1912 it was noted by Miss Leavitt that, when the periods and apparent magnitudes of the variables in the Lesser Magellanic Cloud were plotted as abscissae and ordinates, the points lay on a smooth curve. Since the stars in the Cloud must all be at approximately the same distance from us, this indicates that the absolute brightness is a definite function of the period. H. Shapley subsequently found the same uniformity in a number of globular clusters. The same period-magnitude curve is repeated in each cluster, except that the curve is displaced as a whole towards fainter or brighter (apparent) magnitude, according as the cluster is remote or near. It follows that Cepheids of the same period have the same absolute luminosity, and presumably are alike in all respects. The absolute brightness being identical, the apparent brightness indicates the distance; *e.g.*, if the apparent magnitude of the Cepheids of 5-day period in a particular globular cluster is 13 we know at once that the cluster is 100 times as distant as a Cepheid of apparent magnitude 3; if the 5-day Cepheids observed in a spiral nebula have apparent magnitude 18, the nebula is ten times more remote than the cluster. Thus the general structure of the universe can be plotted out to scale. The scale is made absolute by a study of the brighter and nearer Cepheids which are not beyond the range of ordinary methods of distance determination. The only caution required in using these variables as standard lights for gauging distance is that we must have evidence that their light has not been dimmed by passing through absorbing matter. This point has been carefully studied, and it is believed that (except in particular localities) interstellar space is practically transparent; but the evidence is, perhaps, not beyond reproach.

No theoretical basis for the period-magnitude relation has yet been found. Since the period (as already explained) depends on

the density and the absolute magnitude depends mainly on the mass, it would seem that for a star of given mass there is just one stage in the course of its contraction when it becomes unstable and is thrown into pulsation; at other times it burns steadily. The theoretical conditions for starting and maintaining a pulsation are bound up with the laws of liberation of sub-atomic energy in the interior of the star, as to which little is definitely known (*see* STELLAR EVOLUTION and COSMOGONY). It seems likely that ordinary stars may be near the border line between stability and pulsation, and that some small change in the physical constants of the material occurring when a particular temperature or density is reached puts the star over the borderline.

The typical Cepheid variable which has given its name to the class is δ Cephei. Its period is 5·366 days. It is seven magnitudes brighter than the sun, and is believed to have about nine times the sun's mass. It is a giant diffuse star having a radius of 20 million kilometres, which changes by $\pm 1\frac{1}{4}$ million kilometres in the course of the pulsation. The light-range is 0·6 mag. visual and 1·0 mag. photographic, the difference being due to the fact that the light becomes much bluer at maximum brightness. The "cluster variables" are a sub-class of the Cepheids; they have very short periods usually about 12 hours. The shortest period known is 3·22 hours.

Long Period Variables.—There are very few variable stars with periods between 30 and 100 days, but beyond 100 days and especially near 300 days they become numerous again. The numbers within given limits of period are:

Days	100–200	200–300	300–400	400–500	7,500
Stars	64	194	182	54	12

The leading characteristics of these long-period variables are (1) their light-range is very great averaging 5·5 magnitudes, and in a few stars exceeding 8 magnitudes; (2) the variations do not repeat themselves with the clock-like precision of the other classes of variables, and both the amplitude and period fluctuate irregularly; (3) they are red stars, chiefly of type M, but sometimes of the rarer spectral types N, R, S; during the great outburst of light at maximum, bright emission lines of hydrogen appear in the spectrum.

The enormous variation of light is rather misleading to us, because there is no such large variation in the output of heat. The surface-temperature is varying through a range which happens to be especially critical for the sensitiveness of the human eye The following results relate to Mira Ceti which is the most famous star of this type (discovered by Fabricius about 1596). To the eye at minimum it appears as a faint star of magnitude 9, difficult to distinguish from the numerous other ninth magnitude stars in the field; but the more impartial bolometer, which measures the total radiant energy or heat received, singles it out as a very conspicuous object of bolometric magnitude 1·5. At maximum the surface temperature has risen a little, causing a moderate increase of radiation and bringing it up to bolometric magnitude 0·2; at the same time the character of the radiation becomes more suited to the sensitiveness of the eye, so that an enormous increase of visual brightness occurs. At maximum Mira is generally between mag. 3 and 4 (visual), and occasionally it reaches mag 2.

Accordingly the variation of heat output is not much more than one magnitude, and is much the same as in the Cepheid variables. It is now generally believed that the long-period variables are pulsating stars not essentially different from the Cepheids. They are very diffuse stars of great bulk, and this extreme physical condition is probably responsible for the differences of behaviour between them and the typical Cepheids Pease has succeeded in measuring the angular diameter of Mira with an interferometer, obtaining the result 0″·056. It is probable that the star has a radius of at least 1·5 astronomical units or 300 times the radius of the sun. A number of minor classes of variables are recognized, which differ in material respects from the three chief classes here described. The whole subject of variable stars is now one of the most active branches of stellar research.

STELLAR MOTIONS

We learn about the motion of a star in two ways. Firstly, the change of position in the sky can be observed directly by making from time to time accurate measurements of the position with respect to surrounding stars. The motion thus detected is called ***proper motion***. It is measured in seconds of arc per year; if the distance of the star has also been measured, the result can be converted into miles per second. Secondly, by measurements of the positions of lines in the star's spectrum, the speed of approach or of recession can be found; this radial velocity is given immediately in miles per second, whether the distance of the star is known or not. The two methods supplement one another, the first giving the motion transverse to the line of sight, and the second the motion in the line of sight; combining them we obtain the direction and speed of the whole motion.

Proper Motions.—The stars differ greatly in proper motion. For a naked-eye star a motion of about 3″ per century may be taken as typical. The corresponding change of position would be measurable without difficulty in an interval of ten years For some stars the displacement is less, either because their actual speeds are small, or because their motion is mainly in our line of sight, or because they are very distant. Other things being equal, the stars which are especially near to us will have large proper motions Just as great apparent brightness may be due to nearness or to high intrinsic luminosity, so great proper motion may be due to nearness or to high actual speed; but, in general, great proper motion is a much more dependable indication of nearness than great apparent brightness, and it is used as a criterion to pick out stars likely to have measurable parallaxes from the great majority which are too far away to be measured Proper motions have been measured in tens of thousands; and, moreover, there are methods of quickly detecting stars of large proper motion on a pair of plates of the same region taken at a suitable interval of time (*see* BLINK MICROSCOPE).

The star of greatest proper motion known up to the present is a ninth magnitude star discovered by Barnard, which travels $10\frac{1}{4}''$ per year (more than 300 times the typical speed mentioned above). Even at this speed it would take about 900 years to go from end to end of Orion's belt The following table gives particulars of the stars of largest proper motion:

Star	Mag.	Ann. P M.	Dist (L.Y)	Speed		Lum.
				Trans	Rad.	
Barnard star	9·7	10″·25	6·0	90	−117	·0004
Kapteyn star	9·2	8·76	10·3	131	+242	·002
Groombridge 1830	6·5	7·05	32·0	330	− 97	·23
Lacaille 9352	7·4	6·90	11·2	112	+ 12	·011
Cord 32416	8·3	6·11	14·8	132	+ 26	·009
61 Cygni	5·6	5·20	10·9	82	− 64	·058

The distance in light-years is given in the fourth column, the transverse and radial speeds are given in km. per sec. in the fifth and sixth columns; the last column gives the intrinsic luminosity, the sun's luminosity being the unit. It will be noticed that these are all inconspicuous stars, faint both apparently and actually. Well-known stars which come further down the list are α Centauri and Arcturus, with annual proper motions 3″·66 and 2″·29 respectively. The motions cannot have caused any noticeable change in the appearance of the sky within historic times; but the change in, say, 250,000 years would be considerable, and it is doubtful if any of the familiar constellations except Orion would be recognizable. When the parallax is known, proper motion is converted into linear measure by the formula:

$$\text{speed} = \frac{\text{annual P.M.}}{\text{parallax}} \times 4{\cdot}74 \text{ km. per second}$$

The Solar Motion.—If we examine the proper motions in any small region of the sky, it is at once evident that they are not directed at random; an average motion in a certain direction is plainly shown. Comparing different regions of the sky and allowing for the different aspects of projection, it is found that the stars in the mean are moving in a direction towards the

southern constellation Columba, not far from the south part of Canis Major. The same average motion is also shown by the spectroscopic radial velocities; *i.e.,* the stars in the Columba region have an average motion away from us, whilst those in the opposite part of the sky have an average motion towards us. The effect is so pronounced that a dozen stars taken at random will be sufficient to show the prevailing direction roughly (the first determination by Sir William Herschel was made from seven stars only); but in attempts to fix this important direction as accurately as possible many thousands of stars have been used.

In measuring proper motion, or radial velocity, our standard of reference is the sun; and the foregoing result shows that the stars in the mean are travelling past the sun in the direction towards Columba. This however is rather an egocentric way of expressing the facts. It is more natural to say that the sun is travelling relatively to the mean of the stars in the opposite direction—towards a point in Hercules or Lyra not far from the bright star Vega. This point is called the *solar apex,* and the relative velocity that is found is the *solar motion.* Attempts to determine an accurate position of the solar apex are not very closely accordant, and it does not seem possible to fix it to within 5°. In particular, radial velocity determinations seem to give systematically a lower declination than the proper motions, and bright stars give a lower declination than faint stars. We could scarcely expect the apex to be definite, because the "mean of the stars" is an indefinite conception. The stellar background appears to consist of interpenetrating clusters with different motions, and the relative solar motion will depend on what part of this background is sampled by our observational data. In round figures the general result is: Solar apex, R.A. 270°, dec.+30°; speed 20 km. per sec.

In measuring the parallaxes of stars we use the diameter of the earth's orbit as base line—a length of two astronomical units. The solar motion of 20 km. per sec. transports the observer through 4·2 astronomical units per year, so that observations taken now and 50 years ago give us a base line of 210 astronomical units. With the longer base line it should be possible to survey the stellar system to a distance far exceeding that attainable by parallax measurement. The method cannot be applied to individual stars because the parallactic displacement cannot be discriminated from the star's own motion; but when we are dealing with a class of stars (*e.g.,* stars of 9th magnitude, bright stars of type K, long-period variables, etc.) which are not likely to have any important common tendency of motion as compared with the general mean of the stars, the method will give the average parallax of the class. Fortunately, results obtained in this way can be checked by an independent determination based on similar principles. The *cross* proper motion, or component at right angles to the line towards the solar apex, is a component of the individual motion of the star; the radial velocity (after correcting for the known solar motion) is also a component of individual velocity. Hence, for a class of stars we can find the average value of a component of individual velocity both in arc and in linear measure; comparing the two results we deduce the mean distance. These methods have proved extremely useful in supplementing the meagre knowledge of the distances and absolute luminosities of the stars furnished by direct parallax determinations. For still greater distances the method described under *Cepheid Variables* and analogous methods are employed.

Moving Clusters.—A number of groups of stars have been recognized which share a common proper motion, and evidently form a connected system. We must assume that they have a common origin, *i.e.,* are evolved from the same nebulous condensation. Apparently, having started to move together, they continue to move together simply because encounters which might deflect them are extremely rare. One of the arguments against the existence of great numbers of dark stars in space, is that their passage between the stars of the moving cluster would break it up too rapidly. There is a typical moving cluster in Taurus, studied by L. Boss, which includes many of the stars in the Hyades. The true motions of these stars must be very nearly equal and parallel, otherwise the cluster would rapidly disperse, but as projected on the sky they appear to converge towards one point. As the cluster covers a reasonably large area the convergent point can be found with considerable accuracy. By geometrical construction it becomes possible (without parallax measurement) to determine the distance of each star of the group and to find the precise arrangement of the stars in three dimensions. Another cluster consists of five stars of the Plough together with Sirius and some other bright stars; the sun is in the midst of this moving cluster, so that its members appear in different parts of the sky. The stars of type B seem to have a special tendency to form associations of this kind; one of the best marked groups consists of about 16 stars in Perseus and neighbouring constellations. Perhaps the most important conclusion to be drawn from these clusters is that the stars are not born individually and independently, *e.g.,* by accidental collisions of extinct stars, but that the evolutionary process of star formation is capable of generating a number of stars simultaneously.

The Two Star Streams.—Eliminating the recognized moving clusters, we are left with the general body of the stars whose motions have no obvious association with one another. It is found on examination, however, that their motions are not at random. In 1904 J. C. Kapteyn showed that the proper motions show a decided preference for two favoured directions, apparently implying that the stars around us do not constitute a single system but a dual one. The observed motion of the stars in the mean towards the solar antapex is due to the intermingling of two systems moving in very different directions. These two streams are found to prevail in every part of the sky examined; they are shown both in the proper motions and in the radial velocities. It is not likely that the same stream motion extends throughout the galactic system, but up to the present no limit has been found. Originally discovered in the motions of the bright stars, the phenomenon is found to be essentially the same in stars as faint as mag. 11·5, and there is fragmentary evidence of its occurrence in much fainter stars. The following determinations of the apices and relative speeds of the two streams refer respectively to the bright stars of Boss's catalogue (Eddington) and the Cambridge photographic proper motions of faint stars (Smart). The speed is expressed in terms of a theoretical unit which is probably about 22 km. per second.

	Bright stars			Faint stars		
	R.A.	Dec.	Speed	R.A.	Dec.	Speed
Apex of stream I. . .	91°	−14°	1·52	88°	−12°	1·50
„ „ „ II. . .	288°	−64°	0·86	289°	−73°	0·97
Vertex	94°	+12°	1·87	92°	+20°	1·84
Solar apex . . .	267°	+36°	0·91	273°	+44°	0·88

The first two lines give the motions of the streams relative to the sun, but greater cosmical importance must be attached to the motion of one stream relative to the other, which is given in the third line of the table. The principal difference between bright stars and faint stars lies in their distribution between the two streams. For the bright stars the numbers belonging to stream I. and stream II. are as 3:2, for the faint stars the numbers in the two streams are practically equal. It is for this reason that the declination of the solar apex increases progressively with the faintness of the stars considered; stream II. is receiving more and more weight in the "mean of the stars."

Various attempts have been made to give a dynamical explanation of star-streaming. It was pointed out by H. H. Turner that the comets of the solar system have a preponderatingly radial direction of motion. It might well happen that the orbits of the stars about the centre of the stellar system show the same tendency; in that case, assuming that we are situated at some distance from the centre, the directions to and from the centre would be favoured directions of motion. The vertex or the antivertex would then indicate the direction in which the centre of gravity of the system lies. Others have favoured transverse instead of radial star-streaming, so that the centre of the system would lie 90° from the vertex; this has the advantage that it is possible for

an oblate system of stars to continue in a steady state with transverse, but not with radial star-streaming, but on the other hand it is difficult to see how such a state of motion could originate. Observational evidence as to the direction of the centre of the galactic system does not accord well with either radial or transverse star-streaming. On the whole, Kapteyn's original idea seems the best; we have around us two groups of stars which have come together and are moving through one another.

Stars of type B are aloof from the two star-streams. Their motions (relative to the mean of the stars) are smaller than those of other types, and show little systematic tendency of any kind. A number of stars of other types are associated with them and form a third stream, known as stream O. In most parts of the sky it is difficult to disentangle stream O from stream I, but in regions where the circumstances of projection are favourable the third stream always appears clearly.

Rotation of the Galaxy.—If the galactic system is analogous to a spiral nebula it is presumably rotating in its own plane; in any case its flattened form would lead us to suspect rotation. Several attempts have been made to detect such a rotation from the proper motions of stars, but it is difficult to be sure that the results are not vitiated by the systematic errors of meridian catalogues. A determination by C V L. Charlier, in 1913, gave a general retrograde rotation of the stars in the galactic plane of 0·35″ per century; his more recent result is 0·24″. The rotation appears now to be confirmed by better evidence afforded by the radial velocities. If the rotation were like that of a rigid body the radial velocities, as viewed from any point, would be unaffected; but it is more reasonable to suppose that the angular velocity diminishes outwards from the centre of the system, as with the planets in the solar system. Then, if we take a group of stars surrounding the sun, those between us and the centre will be gaining on us and those outside us will be lagging behind. This shearing motion distorts a square into a parallelogram, that is to say one diagonal is lengthening and the other diagonal is shortening; so if we observe stars in two opposite regions of the sky, corresponding to the direction of one diagonal, these should be receding from us, and along the other diagonal, 90° away, the stars should be approaching us, on the average J. H Oort has found that this effect is quite prominently shown in the observed radial velocities, and that the direction of the galactic centre deduced from it accords well with the direction generally accepted (deduced from the distribution of globular clusters). Moreover, taking different classes of stars, the positions found for the centre are very accordant, and the effect increases, as it should do, proportionately to the mean distance of the class Our survey covers only a relatively small region of the galactic system, but we can at least say that in this region the stars have systematic motions which shear the distribution in the same way as orbital motion about the centre of the galaxy would do It is possible, however, that other physical explanations of this behaviour might be given.

Individual Motions.—After eliminating all systematic motion there remains the individual motion of the star itself An interesting field of study arises from the correlation between individual speed and other characteristics, such as mass, spectral type, brightness The earliest result of this kind was found by W W. Campbell and J. C. Kapteyn in 1910; viz, a progressive change of mean speed with spectral type Campbell's results for bright stars were. Type B, 6 5 km. per sec ; A, 11; F and G, 15; M, 17 km. per second. The figures refer to the radial component only, and must be doubled to give the mean speed in three dimensions At the time it was thought that this sequence of types represented the order of evolution, so that the progression implied that the speed of the stars increases with their age; with the recognition of giant and dwarf stars this interpretation has become inadmissible Actually type M consists of two distinct classes, viz., very diffuse stars supposed to be in the earliest stage of condensation from a nebula, and very dense stars supposed to be at the end of the evolutionary sequence; both classes have high speeds, the latter being particularly large. Generally speaking, faint stars have greater speeds than bright stars; owing to the mass-luminosity relation this means that stars of small mass have greater speeds than massive stars. It has been suggested that there is a law of equipartion of energy so that the average value of $\frac{1}{2}mv^2$ is the same for all classes of stars; this might have a dynamical explanation, since the speeds of the molecules of a gas distribute themselves according to the same law. Up to a certain point observations agree with the equipartion law, but there are noteworthy exceptions; the massive B stars have low average speed as the law requires, but the most massive stars of all, type O, have rather large speeds The present position is that our knowledge of the factors determining the mean speed of different kinds of stars is made up of fragmentary correlations, and has not yet led to any generally comprehensive theory.

One complicating factor is the asymmetry of high velocity stars, which has been discovered by J. H Oort and G Strömberg. According to Oort, stars with speed greater than about 60 km. per sec. are moving almost exclusively towards one hemisphere of the sky. It seems reasonable to interpret this critical speed as the "velocity of escape" from our local star-cloud. Stars with velocity below the velocity of escape are permanent members of the star-cloud, and describe orbits within it under its gravitational attraction; on the average, therefore, they move as much in one direction as in the opposite. Stars with velocity above that of escape cannot be permanent members; they pass once through the system and do not return; accordingly they may well show an asymmetry of motion, dropping into our star-cloud from a cluster or clusters on one side of it, passing through it, and not returning. The value of the velocity of escape is more or less what we should expect from our general knowledge of the extent of the star-cloud and the number of stars per unit volume.

About 18 stars are known within a sphere of 4 parsecs radius surrounding the sun, *i e.*, having parallaxes greater than 0·25″; there may be a few additional faint stars yet to be detected Many of these near neighbours are red dwarfs with masses one-quarter or one-fifth that of the sun; on the other hand a considerable proportion are double stars (here counted as one). The total mass within the 4 parsecs sphere may be estimated at about 12 times the sun's mass If this may be taken as the general average density of our star-cloud, it is possible to calculate the orbital period of the stars moving within it under its gravitational attraction; for the periods of orbits in a sphere of uniform density are isochronous, and depend only on the density and not on the size of the sphere. The period would be 200 million years In addition to the mass of the lucid stars there may be other masses in the sphere, *e.g*, dark stars or scattered nebulous matter of great tenuity. These added masses would shorten the period; but we cannot allow the period to be shortened very much, because then the stars in the largest orbits, hurrying to get from one side of the star-cloud to the other and back again in the prescribed period, would need to have greater velocities than we observe. Dark stars and nebulous material together cannot amount to many times the mass of the lucid stars. At the end of this article direct observational evidence will be given for the existence of a cloud of diffuse matter in interstellar space. This must be extremely rarefied; one atom per cubic centimetre is the most we can possibly allow consistently with the dynamics of stellar motions

CONSTITUTION OF THE STARS

Density.—When the mass and radius of a star are known, the mean density of the material can be calculated immediately. Direct determinations of the *mass* are only available for double stars; but for other stars the mass may with some confidence be inferred from the absolute magnitude by means of the mass-luminosity relation described later in this section. In any case the range of stellar masses is so restricted that errors are not likely to affect the general order of magnitude of the densities deduced. The *radius* R may be calculated from the absolute luminosity and the observed surface-temperature. Other things being equal, the luminosity is proportional to the area of the surface, *i.e.*, to R^2, but allowance must be made for the different

radiating power of surfaces at different temperatures; this allowance can be calculated from the laws of radiation (Planck's law). For a few stars the radii deduced in this way have been confirmed by direct measurement of the apparent angular diameter of the disc with Michelson's interferometer. In this way we find that some of the red giant stars, such as Betelgeuse, Antares, Mira, have densities less than $\frac{1}{100}$ that of air; Capella has a mean density nearly equal to air; the sun, we already know, has a density 1·4× water; the faint red dwarfs have density about 10× water. For the class of stars called *white dwarfs,* which includes the companion of Sirius (*see* SIRIUS), the method gave an enormous density 60,000 times that of water; this result was at first regarded as incredible, but it now appears probable that it is to be accepted literally.

For the more diffuse stars it is evidently legitimate to treat the stellar material as perfect gas. The study of stellar equilibrium thus reduces to the study of the equilibrium of a globe of perfect gas held together by its own gravitational attraction. It was thought that the simple theory must break down for stars of higher density (such as the sun) owing to the deviations from the laws of a perfect gas; but in 1924 it was found by Eddington that the dense stars agreed observationally with laws which had been deduced theoretically for gaseous stars. The fact is, that at the temperatures of the order of ten million degrees occurring in the stellar interior, the atoms are stripped of all their outer electrons and reduced to ions of very small dimensions; consequently the jamming of atoms against one another, which causes the breakdown of the gas laws, does not occur in the stars until far higher densities are reached. The high density found for the white dwarfs confirms this conclusion; close packing is possible because the atoms have lost their balloon-like envelopes. In all stars other than white dwarfs the material may be treated as perfect gas, except that in the stars of least mass (red dwarfs) there is a small correction arising from the electrostatic forces between the ions which makes the gas *superperfect, i.e.,* makes it deviate in the opposite direction to the deviations of *imperfect* terrestrial gases.

Internal Temperature and Pressure.—The distribution of temperature and density in a sphere of gas in equilibrium under its own gravitational attraction is a classical problem studied by Lane, Ritter, Emden and others. The mathematical analysis developed in these earlier researches is used in the modern theory, but three new features have been introduced. (1) It used to be supposed that the heat radiated from the star's surface into space was brought up from the interior by convection currents, but it has now become evident that it is transferred by radiation. Accordingly the stars are now assumed to be in *radiative* equilibrium instead of in *convective* equilibrium. The condition of radiative equilibrium is that each region must have settled down to a temperature at which it radiates an amount of heat equal to that which it absorbs from the radiation passing through it. One simplification resulting from this change is that we no longer need to know the ratio of specific heats of stellar material—a physical constant difficult to estimate. (2) Radiation-pressure is sufficiently great to play an important part in the equilibrium, especially of the massive stars, and it is now taken into account. (3) Formerly the average molecular weight of the stellar gas was taken to be the weight of the atoms likely to preponderate, *e.g.,* iron (at. wt. 56). It is now recognized that the atoms in the interior will be highly ionized; most of the electrons which circulate round the nucleus will have broken loose, and must be counted as independent "molecules." Taking this into account the molecular weight will be slightly over 2, a result nearly independent of the chemical constitution of the star provided only that there is not an excessive proportion of hydrogen. Owing to this decrease in the adopted molecular weight, the internal temperatures are considerably lower than those calculated on the older theories.

Since it is believed that a star's heat is maintained by liberation of sub-atomic energy, another unknown condition enters into the problem, viz., the distribution of sub-atomic sources in the interior. This, however, has no very important effect on the main results of the investigation, and, by considering the extreme cases of a source wholly concentrated at the centre and a source evenly distributed through the mass, we can set limits to the uncertainty.

For the sun the central temperature is found to be of the order 40,000,000° C. The mean temperature (averaged for equal mass) is 23,000,000°, and is less subject to uncertainty arising from ignorance of the distribution of the source of energy and other data. Moreover, all stars of the Main Series (*see* STELLAR EVOLUTION) have nearly the same internal temperature. The Main Series, which comprises the great majority of the stars, includes B type stars several hundred times more luminous than the sun, and red dwarfs, giving a hundredth or a thousandth of its light. It is remarkable that stars differing so widely in mass, in output of heat and light, and in surface temperature, should be so uniform in internal temperature. The giant stars have lower internal temperature, *e.g.,* Capella, which is of the same spectral type as the sun but has only $\frac{1}{800}$ of its density, has a central temperature 10,000,000°.

The temperature gradient from the centre to the surface causes a flow of heat outwards, which is hindered by the opacity of the stellar material; hence, knowing the temperature distribution in the interior, and having observed the total outflow of heat from the star (*i.e.,* its luminosity reduced to heat units) we can compute the opacity. This astronomical opacity may be compared with the theoretical opacity for material of the density and temperature concerned, as calculated from the modern theory of the atom. At present the results are not fully accordant, the astronomical opacity being about 12 times the calculated opacity, *i.e.,* the stars are about three magnitudes fainter than we should expect. The discrepancy is, however, the same for all stars, so that, if instead of attempting to predict theoretically the absolute brightness, we use the law of variation of opacity with density and temperature to predict differences of brightness, the agreement is very good.

The Mass-luminosity Relation.—Having calculated the temperature distribution in the star by the condition of radiative equilibrium, we find the following formula for the total outflow of heat L (in ergs per second):

$$L=4\pi cGM(1-\beta)/k,$$

where c is the velocity of light, G the constant of gravitation, M the mass of the star (in grams); k the coefficient of opacity, and $1-\beta$ the ratio of radiation pressure to the whole pressure, obtained by solving the quartic equation,

$$1-\beta=0{\cdot}0031\,M^2\mu^4\beta^4,$$

where M is now expressed in terms of the sun's mass, and μ is the average molecular weight in terms of the hydrogen atomic weight. Knowing L and M for any star we can calculate k; for example in Capella we find $k=120$ C.G.S. units. This means that a screen containing $\frac{1}{120}$ gram. per sq.cm. (equivalent to about 6 cm. of air) would stop about two-thirds of the radiation passing through it. At first sight this is a surprisingly high opacity. The old problem as to how the heat is brought up from the interior of a star to replace that radiated from the surface, has completely changed; we see rather that the star has to be constructed of highly opaque material in order to hold back the internal heat and permit it to come to the surface no faster than it does. The high opacity is, however, not so surprising when we realize that at ten million degrees the radiation in the interior consists of X-rays chiefly of wave-length 2 to 6 Ångstroms, which are highly absorbed in a few millimetres of air. In fact the stellar opacity is less than the observed opacity in the laboratory—a fact explained by the high ionization of the stellar atoms, which throws a great part of their absorbing mechanism out of order.

According to modern theories of X-ray absorption, the coefficient of opacity should (approximately) be proportional to the density and inversely proportional to the $\frac{7}{2}$ power of the temperature ($k\propto\rho/T^{\frac{7}{2}}$). By the use of this law we can eliminate k from the equation given above and obtain the relation between L and M. The density of the star nearly disappears from this relation, so that the total radiation or absolute bolometric magni-

tude of a star is a function of the mass and molecular weight only, apart from a trivial correction dependent on the density, which can be calculated and applied when the spectral type is known This predicted relation between L and M can be plotted as a graph; it is called the mass-luminosity relation. It appears to be well confirmed by all the observational data available; but it must be remembered that accurately determined masses are rare, so that the test is not so complete as we should desire. The mass-luminosity relation cannot conveniently be expressed by an algebraic formula, but as a rough guide it may be stated that the heat outflow from a star varies as the third or fourth power of the mass in the most important part of the range.

These results are mainly independent of the assumed chemical constitution of the stars, owing to the fact that the average molecular weight for all elements except the lightest turns out to be nearly 2 when account is taken of ionization; but for stars composed mainly of hydrogen the mass-luminosity relation would be greatly altered. It may be inferred, therefore, that the stars do not contain an excessive proportion of hydrogen.

It is interesting that we should be able to learn anything at all about the chemical composition of the inaccessible interior; but the fact has also a definite bearing on theories of the source of a star's heat One theory suggests that the store of energy needed to maintain the star for thousands of millions of years is provided by the evolution of higher elements from hydrogen. (Hydrogen, which consists merely of protons and electrons is perhaps best regarded as *unformed matter*.) By cutting down the admissible proportion of hydrogen to, say, 10%, we reduce the supply from this source to one-tenth, and it becomes very doubtful whether it will suffice Secondly, by admitting that 90% of the star must consist of "formed" matter, we must suppose that the main process of formation of matter occurs in a pre-stellar stage Evolution of the elements is, therefore, in the main a low temperature process and, perhaps still more surprisingly, a low density process.

Radiation-pressure.—At any point in a star, gas-pressure and radiation-pressure together support the weight of the layers above. The proportion supported by radiation-pressure $(1-\beta)$ is found by a quartic equation already given To a first approximation it is the same in all parts of the interior, and is independent of the star's density; the molecular weight being given, it depends only on the star's mass. It is remarkable that for stellar masses there is no great disparity between radiation-pressure and gas-pressure, whereas for masses of a different order $1-\beta$ would begin 00 or ·99 It seems clear that the condition of rough equality of the two pressures has in some way determined the size of the aggregations of the primitive matter of the universe The simplest view is to suppose that, when radiation pressure amounts to say one-tenth of the whole pressure, it renders the aggregation of further material more difficult or makes the mass more liable to break up Hence larger masses are more and more rare Gravitation by drawing together the primitive nebulous material will, in general, build up masses to a size at which radiation pressure first begins to offer serious opposition to further increase It is now widely believed that the stars radiate away a large part of their mass during their life-time; hence it is fairest to consider only the youngest stars—those in the most diffuse state; 90% of these have masses (deduced by the mass-luminosity relation) between two and one-half times and five and one-half times that of the sun, corresponding to values of $1-\beta$ between ·17 and ·35 If the rise of radiation to importance plays a part in limiting the masses of the stars, this is just the range which we should expect to be most critical.

STELLAR SPECTRA

We deal rather briefly with this branch of the subject since some of the more interesting developments are treated under ASTROPHYSICS, STELLAR EVOLUTION, SUN. By the appearance of their spectra (*see* SPECTROSCOPY) stars are arranged in a sequence of types O, B, A, F, G, K, M. This turns out to be the order of decreasing surface temperature. The "effective" surface temperatures of stars are calculated by Planck's law of radiation (for theory, *see* RADIATION) from the relative intensity of the continuous spectrum for different wave-lengths; the higher the temperature the more the region of maximum intensity is displaced to the violet. For the sun this method of finding the equivalent black-body temperature is checked by calculating also the temperature corresponding to the absolute intensity of its radiation; so presumably it will apply to other stars, although we have not usually any direct check. Good indirect confirmation of these temperatures has been afforded by studying the spectral indications of ionization of the elements (*See* below.) The following temperature scale is a combination from various sources; the results are in degrees absolute

Type	Temperature	Type	Temperature
	°		°
B0	20,000	G0	5,500
B5	15,000	G5	4,700
A0	11,000	K0	4,000
A5	8,500	K5	3,300
F0	7,500	M0	3,000
F5	6,500		

This refers to giant stars; dwarf stars of the same type are about 500° hotter The radiating power of the surface in heat units is proportional to the fourth power of the temperature.

In all the later types the stars fall into two groups, the *giant* or diffuse stars, and the *dwarf* or dense stars They are most widely distinct in type M, and converge to coalescence in types A and B. If, instead of arranging the stars in order of surface temperature, we put them in order of increasing density, we must start with the giants of type M, follow the giant branch through K, G, F until it coalesces with the dwarf branch in types A and B, and then continue along the dwarf branch in the reverse order A, F, G, K, M. It is natural to suppose that the order of increasing density is that of evolution, and accordingly we seek a theory of evolution which will be consistent with this order.

Following this supposed order of evolution, the temperature of the surface starts very low, increases to a maximum, and then decreases again, the giant stage being one of ascending temperature, and the dwarf stage of descending temperature This fact, which was stressed in early theories, has probably no great significance, since the surface temperature does not correspond at all closely to the internal temperature It is more important to note that the mass (corresponding closely with the luminosity) is nearly steady in the giant sequence, perhaps decreasing slightly, and then diminishes rapidly as we pass down the dwarf sequence It seems impossible to retain our general ideas of stellar evolution without admitting that the mass of a star decreases substantially during its life-time Radiation is the principal cause of loss of mass by a star, and hence we are inclined to believe that a large part of the mass of a star is convertible into radiation—in short, matter must disappear, its energy of constitution being released as aether waves Admitting this source of energy, the age of the stars is of the order of a billion (10^{12}) years or more In fact, we can calculate the time taken for a star to evolve from one type to another by reckoning how long it would take for its observed radiation to carry away the necessary amount of mass In the latest dwarf stages, when the radiation is feeble, evolution will be very slow, and the sun may continue to shine with increasing feebleness for 300 billion years before it reaches the last stage of the sequence type M (dwarf).

After the first use of spectroscopy to identify chemical elements in the atmosphere of a star, the most important advance was the discrimination of "enhanced lines," *i e.*, lines strengthened in the spark spectrum as compared with the arc. Much of the early progress in this direction was due to J. N Lockyer and A. Fowler. In general, enhanced lines are those due to the atom with one electron missing (singly ionized atoms), the arc lines being due to neutral atoms. The spectra of all the important elements have now been unravelled, and we can say at once which lines belong to neutral atoms, which to singly ionized, which to doubly ionized atoms, etc. Thus it is found that in some stars the atoms of calcium in a position to form an absorption spectrum are neutral, in others they are singly ionized, in others doubly

ionized. Clearly this is a clue to the physical conditions in the outer layers of a star. The modern thermodynamical theory of ionization was brought to bear on the astronomical observations by M. N. Saha in 1920, and has dominated all recent progress. The degree of ionization depends on both the temperature and pressure, the former representing the factor which causes the breaking away of electrons and the latter the factor which determines their opportunity of recombining. By connecting together the data for different elements and controlling the results by reference to other methods of determining stellar temperatures, much information has been obtained as to the temperature and pressure in the reversing layer. In particular it is found that the pressure is generally between 10^{-3} and 10^{-4} atmospheres—much lower than used to be supposed.

Spectroscopic Parallaxes.—Since the nature of the spectrum shown by a star is conditioned both by the temperature and pressure of the reversing layer, a complete classification of spectra should be two-dimensional. Ordinarily we recognize only a linear series—the Draper sequence of types considered above; but by attention to detail we can recognize also a classification transverse to this. Taking the Draper sequence to correspond roughly to temperature, the transverse classification will correspond to pressure. Since low pressure favours ionization, it will be marked in the spectrum by great strength of the enhanced lines relatively to the arc lines. The giant and dwarf stars of the same spectral type can easily be distinguished from one another by this method; the reversing-layer pressure is low in the giant stars owing to the small value of gravity at the surface.

It was early recognized by E. Hertzsprung that those spectra marked by Miss Maury as having the "*c*-characteristic" belong exclusively to the giant stars. This characteristic is an unusual fineness of the lines—a feature which also results from low pressure. More precise criteria were found by Adams and Kohlschütter in 1914; and the method has been developed by Adams into a means, not only of distinguishing giant and dwarf stars, but of determining quantitatively the absolute luminosities of stars. At present the procedure is empirical; the curve connecting absolute magnitude with differential intensity of certain selected pairs of spectral lines is deduced from and tested by stars of known trigonometrical parallax; it is then applied to find the absolute magnitudes and hence the distances of other stars. Parallaxes of some thousands of stars determined in this way have been announced, and are known as spectroscopic parallaxes. The underlying principle of the method may be summarized as follows: Stars may differ in mass, and stars of the same mass may differ in density; but, when the mass and density are given, no other important difference can occur, and the luminosity, surface temperature and pressure in the reversing layer should be uniquely determined; hence the spectrum should be determinate. Conversely, a sufficiently close examination of the spectrum (its position both in the Draper sequence and in the classification transverse to it) should fix the mass and density of the star, and hence its other physical properties, including luminosity. Ideally the deduction of luminosity might be made theoretically, but in any case the connection between luminosity and spectrum can be observed experimentally and formulated as an empirical law.

Calcium Cloud in Space.—In certain spectroscopic double stars the phenomenon of "fixed calcium lines" is observed. Whereas the other spectral lines shift to and fro as the star approaches and recedes in its orbit, the H and K lines of ionized calcium remain stationary. It is clear that somewhere between us and the star's photosphere there must be an absorbing cloud of calcium vapour which does not follow the star in its orbit. The phenomenon was first pointed out by Hartmann in 1904 for the star δ Orionis. Later Miss Heger discovered that the D lines of sodium also remain fixed in δ Orionis. The same behaviour has now been observed in a large number of stars, but no other "fixed" spectral lines have been found. The important question to decide is whether the cloud belongs to the double star or whether it is a continuous cloud filling interstellar space. J. S. Plaskett has shown that the latter alternative is correct; the motion of the calcium cloud is often different from that of the centre of mass of the star. After removing the solar motion the velocity of the cloud relative to the mean of the stars is found to be small. Just as there are lines in the solar spectrum which do not share in the sun's rotation and are accordingly to be attributed to absorption during the passage of the light through the earth's atmosphere, so we have fixed lines of calcium and sodium which do not share in the orbital or individual motion of the star and are to be attributed to absorption in an interstellar "atmosphere." The fixed lines only appear in the spectra of the hottest stars, but that is perhaps due to the fact that cooler stars have strong H and K lines of their own, masking the lines of the cloud, or because the cooler stars, being less luminous, are not observed at a sufficient distance to give the cloud absorption a chance. It has been suggested that the presence of the hot star is necessary in order to ionize the calcium vapour and render it capable of absorbing H and K light, so that although the absorption is performed by the interstellar cloud only the parts of the cloud stimulated by the star are effective. But this explanation would not hold good for the D lines of sodium which are absorbed by un-ionized unexcited atoms. There can be little doubt that the absorption occurs along the whole track of the light through space, and the intensity of the lines should be an indication of the length of track, that is of the distance of the star. This appears to be confirmed by the researches of O. Struve, who has found that the strength of the fixed lines increases steadily with the average distance of the objects observed.

In order to avoid a huge mass of the stellar system inconsistent with the observed velocities of the stars, it must be postulated that this interstellar cloud is of very low density. About one atom per cubic centimetre is the maximum that can be allowed. It is calculated that matter so diffuse as this would take up a high temperature not much lower than the photospheric temperatures of the stars; although a black body in interstellar space would sink to a temperature of 3° absolute. The density is too small to give any appreciable scattering or absorption of light in space other than the special line-absorption of calcium and sodium light.

STAR APPLE (*Chrysophyllum Cainito*), an evergreen tree of the family Sapataceae (*q.v.*), called also cainito, native to tropical America and cultivated for its edible fruit. The pleasantly flavoured fruit, 2 to 4 in. across, is apple-shaped. In a cross-section of the unripe fruit the seed-bearing cells form a star.

STARAYA RUSSA, a town of Russia in the province of Novgorod, in 58° N., 31° 22′ E., on the river Polista, by means of which and Lake Ilmen it is brought into steamer communication with Leningrad. Pop. (1926) 21,511. Brine springs on the east of the town were used as a source for the supply of salt as late as 1865; at present they are used only as mineral waters (temperature 51–54° F), having a great resemblance to those of Kreuznach in Germany. Some thousands of visitors were accustomed to resort to them every summer, and owing to this circumstance Staraya Russa was better built and better kept than any other town in the government of Novgorod. The inhabitants are supported chiefly by the summer visitors. There is a trade in rye, oats and flax. The name of Staraya Russa occurs in Russian annals as far back as 1167. It belonged to the republic of Novgorod, and suffered continually in the wars between Russia, Lithuania and Livonia. It was afterwards annexed to Moscow.

STARA ZAGORA, the capital of a department of southern Bulgaria lying on the southern slope of the Karaja Dagh, 70 m. N.W. of Adrianople, with which it is connected by railway. Population (1926), 28,929. The city is surrounded by vineyards,

and has flour-mills, breweries, brandy distilleries, copper foundries and tanneries The production of silk and attar of roses is carried on in the district, which contains numerous mineral springs, and there is a trade in corn and wine. It is the junction of the trans-Balkan and Burgas-Philippopolis railway lines. It was destroyed during the Russo-Turkish war (1877–78) and rebuilt on modern lines During the rebuilding, important Thracian, Roman, Byzantine and Turkish antiquities were discovered.

Stara Zagora, founded probably by the Thracians, was known to the Romans as Augusta Traiana, but afterwards, to distinguish it from a Macedonian town of this name, it was named Beroe or Berrhoea. By the Turks the name was changed in the 17th century to Eski-Zagra or Eski-Zaara, whence its Bulgarian name

STARCH. This is perhaps the most widely distributed substance in the vegetable kingdom and occurs, often in great abundance, in almost every plant. Pure starch has the appearance of a white, glistening, friable powder, and possesses a harsh feel when rubbed between the fingers; it is tasteless, has no smell, is not soluble in cold water and undergoes no change when exposed to the air. When examined under the microscope it is found to consist of granules of definite shape, size and appearance These show very wide variations, some being minute while others attain a comparatively large size; they are, nevertheless, quite characteristic of the plant from whence they are obtained, and the identification of any particular starch by comparison with those of known origin is a more or less simple matter Granules or cells which are usually oval in shape are found to be composed of a series of concentric layers arranged around a nucleus or hilum which appears as a dark spot, the outer layers being the oldest in point of growth

Starch belongs to the group of carbohydrates in which are included the sugars, gums and cellulose, and is composed of the elements carbon, hydrogen and oxygen Its constitution is very complex, but it is built up in the plant from two simple compounds, water and the carbon dioxide gas present in the atmosphere, through the agency of the green colouring matter, chlorophyll, under the activating influence of sunlight The rôle of starch in plant economy is that of a reserve material, and as such it must be transferred from the leaves and other green parts of the plant, where it is formed, to more permanent quarters To facilitate this migration it is broken down into sugars which dissolve in the cell juice, in this way passing through the cell walls of the plant finally to become reconverted into starch, either in the fruit or seeds, or in the bulbs and tubers as the case may be It is thus rendered available as a source of sustenance for the young plant until it is sufficiently advanced to carry on the process of starch formation itself. The starch granule is composed of two distinct but similar compounds, amylose and amylopectin, the former being in considerable excess, and although it is quite insoluble in cold water, when mixed with hot water the cells rupture considerably below boiling point, and form a viscous, jelly-like liquid which is known as "starch paste," setting into a solid mass on cooling When starch paste is heated with dilute acids the starch is first converted into the soluble form and, by a process known as hydrolysis, is subsequently changed into a series of sugars, the principal of which are dextrin, maltose and glucose This process is employed in the manufacture of corn or glucose syrup, used very extensively in confectionery, and of glucose sugar used in brewing Hydrolysis is also effected by certain natural ferments or "enzymes" such as those present in saliva, pancreatic juice, malted grain (diastase) and in fact all germinated seeds, and it is the latter agent which is employed in the fermentation industries—brewing, distilling, etc—converting the starch in the materials used into material capable of fermentation by yeast The development of starch in the growing plant already referred to, and the rebuilding of the soluble products into the cellulose which constitutes the tissues, is carried out by ferments or enzymes elaborated by the plant itself, while a similar process goes on in the human system when starchy foods are eaten and converted into soluble sugars capable of assimilation.

Dry starch heated to about 320° F is transformed into dextrin, a pale, yellowish powder soluble in water, known as British gum

A very sensitive reaction of starch is the production of an intense blue coloration with a solution of iodine, a characteristic much used in its identification.

The average starch content of the principal starch yielding plants, together with the temperatures at which the purified starch gelatinizes when heated with water, are, according to Lippmann, as in the following table:

	Average Starch content %	*Gelatinising temp. ° F*
Potato	18–20	145
Wheat	54–58	152
Barley	40–46	145
Oats	35–38	
Rye	44–46	131
Maize	55–65	145
Rice	70–79	142
Millet	53–55	
Peas	39–40	
Lentils	39–40	
Arrowroot (*Maranta arundinacea*)	26–39	158
Tapioca (*Jatropha manihot*)	25–40	156
Yams (*Batata edulis*)	25–35	. .
Sago		158

The storehouse, or starch-containing part of the plant, consists of a network of cells, within the walls of which the starch granules are closely packed together The process of manufacture involves the rupturing of the enveloping cell walls and separation of the starch from the associated material by levigation

Manufacture.—The manufacture of starch from roots and tubers is usually carried on in the locality in which they are grown; that from potatoes on the continent of Europe, principally in Germany, France and Holland; arrowroot, cassava and tapioca are prepared from the roots and tubers of the maranta and manioc plants in the West Indies and South America; sago is manufactured from the pith of the sago palm and also from the yams or sweet potatoes in the East Indies and Borneo. Cereals can be more readily transported and stored, so locality is a matter of convenience; thus rice is used as a raw material in England, France, Germany and Italy and other parts of Europe, while maize is used very extensively in North America, and in England, France and Germany. Wheat is not now largely employed

The purposes for which starch is manufactured can be classified under three heads·

(*a*) *Industrial* These include sizing yarn and cloth in the textile industries; dressing cloth, thickening mordants and colours in calico printing; the preparation of British gums and dextrin, confectioners' glucose or corn syrups, and sugars for use in the fermentation industries

(*b*) *Food* Used alone in the form of cornflour, arrowroot, tapioca, sago, etc, or in conjunction with other substances in the preparation of custard and blanc mange powders, macaroni, semolinas, sauces, cocoa, confectionery, etc.

(*c*) *Laundry* In pipe or crystal form and powders, both "thick" and "thin boiling" preparations

The suitability of starches from various sources for these purposes depends on their cost, purity, the stiffness or viscosity of the paste they make with hot water and the size of the granules Potato, maize, rice and wheat starches are those chiefly used for industrial purposes; rice, maize, arrowroot, cassava and sago for foodstuffs; and the small granuled starches, rice and maize, are used extensively in the laundry owing to the fact that the granules are required to enter the texture of the linen or cloth before becoming gelatinized by the hot iron

The general principles for dealing with all types of roots and tubers are substantially the same, but of course vary in their elaboration and efficiency in different parts of the world, and they also only differ to some extent in detail when cereals are being treated They are briefly as follows:—The tubers first go through washing machines where earth, stones, sand and grit are removed; they then pass to a rasping machine where all the cells are completely ruptured. The resulting pulp is washed in a fine stream of water on fine-mesh brass sieves, which separate the starch from vegetable fibre, etc; the resulting milky starch liquor is run into vats to separate fine sand and grit by settlement, through fine silk sieves for further purification, and is finally allowed to run very

slowly over long, shallow, wood troughs, runs or tables, where the pure starch settles out and the impurities pass off at the ends with the water. The pure white starch is washed from the runs by a jet of water and is pumped to either filter presses or hydro extractors, which remove all except about 40–45% of the water, leaving the starch in the form of a damp cake.

The cereals contain varying proportions of protein or gluten material associated with the starch, and special methods have to be employed in their preliminary treatment. The protein contained in rice is found to be rendered soluble by very weak caustic soda solution, and advantage is taken of this in the production of starch from the raw material.

Maize in addition to protein contains an oil-containing germ which it is necessary to remove. In this case the grain is first steeped for 2 to 4 days in warm water containing 1% of sulphur dioxide, ground in burr stone mills, and the resulting diffluent mass diluted with water is passed through a long V-shaped tank where the germ floats and is skimmed off.

Wheat contains gluten which forms an elastic paste with water and cannot be removed by levigation. The procedure carried out in this case is to reduce the grain to flour which is then made into a dough with water, divided into small pieces and placed in a semicircular silk or fine brass sieve where a travelling roller presses out the starch which is removed by a fine spray of water. The starch liquor goes through a very similar purification process to that employed for maize, often being treated with dilute caustic soda solution to swell the gluten and assist its removal between the sieving processes. It is necessary to carry out the final drying process at very low temperatures to prevent the gelatinization of the starch granules. Several methods, similar in principle for starches from all sources, are in use in the large factories, and consist of either bringing the starch lumps or blocks in contact with a continuous current of warm air, or evaporating off the excess of moisture in a vacuum chamber. For producing the starch in the form of powder or flour the moist lumps are either placed on an endless band running backwards and forwards in an enclosed chamber through which warm air is drawn, or they are placed on trays mounted on a trolley and passed through a tunnel in contact with warm air. In the tropics drying is usually carried out in the open air.

Prism or crystal starch is prepared from maize or rice starch for laundry purposes, and is produced by forming the damp starch into blocks by draining off the water from the starch liquor in boxes with perforated bottoms covered with filtering cloths; the blocks are cut into two or more sections which are partly dried in a warm chamber; the yellowish brown crust which forms on the outside is scraped off, and the blocks wrapped in paper, returned to the drying chamber and dried very slowly. Under this treatment the blocks break up into irregularly shaped prisms technically termed "crystals."

Pearl tapioca is made by heating the slightly moist starch from manioc in a steam heated copper pan with constant stirring, some of the cells becoming gelatinized and adhering together in small, irregular masses. Further drying follows and the crude lumps are passed through rollers and graded.

Granulated or pearl sago is prepared by drying the starch in such a way that it forms a plastic dough in which a portion of the granules have become gelatinized, forcing this through sieves, and drying the resulting granules in the air.

STAR CHAMBER, the name of an apartment in the royal palace of Westminster, a meeting-place of the king's councillors, derived from stars fashioned on the roof, perhaps, of the hall. By derivation, later on, the name of councillors and judges sitting there as a court.

In 1398 repairs of the "Sterred chambre" are mentioned. In 1453 a meeting "in concilio nostro" (in our council) was held "in the Sterred Chambre." In 1542 a law provided punishment for those convicted "in the Starr Chamber at Westmynster before the Kinges most honorable Counsell."

In the middle ages judicial functions were exercised by the king of England and his council. The crown never parted with supreme jurisdiction. The council shared it, and also did judicial work not specially delegated to the particular courts which had evolved from the *curia regis*. The king's council, in Star Chamber and elsewhere, was reinforced by judges of the royal courts and by various others. From time to time parliament defined and approved this judicial work. In 1487 a statute (3 Henry VII., c. 1)—for a long time mistakenly supposed to have established the court of Star Chamber—named a commission of seven principal councillors and two of the judges, to try offenders too great to be dealt with by ordinary courts.

In the sixteenth century councillors, judges, persons specially summoned, additional "counsel," and great lords sometimes attending, acted either as a council or a court in Star Chamber, records being kept by clerks.

Councillors and judges sitting in Star Chamber were more and more thought of as the court of Star Chamber. They dispensed much justice and heard many cases often by desire of the parties concerned. Hearings were public; there was no jury; torture was sometimes used to get confession. Generally speaking, it was a court of criminal jurisdiction, particularly in respect of violation of royal proclamations; but "all offences may be here examined and punished if the king will." Sentence of death was never pronounced. The court punished with imprisonment and with fine, even with mutilation.

Under Elizabeth attendance at Star Chamber approximated to that at privy council, with reinforcement of judges, so that the two bodies were differentiated in function rather than in personnel. Under James I. and Charles I. Star Chamber continued as an active, important court, largely respected and liked. As Puritan and parliamentary opposition developed, however, it incurred odium from severe penalties, and the reputation then affixed by enemies has since persisted. In 1641 it was abolished by an act of the Long Parliament (16 Charles I., c. 10). At the same time the judicial power of councillors in privy council was abridged.

(1792); I. S. Leadam, *Select Cases before the King's Council in the Star Chamber* (1903, 1911); Cora L. Scofield, *Court of Star Chamber* (1900); E. P. Cheyney, *History of England*, vol. i. (1914); E. R. Turner, *The Privy Council*, vol. i. (1927); A. F. Pollard, in *English Historical Review*, July, Oct. 1922, Jan. 1923. Star Chamber pleadings are in the Public Record Office, London; court records and decrees have disappeared. (E. R. T.)

STAR CLUSTER. In surveying the sky we find regions here and there where the stars are much more richly strewn than usual. Some of these are clusters, where hundreds or thousands of stars are seen concentrated together in a small field of view, providing show-objects—beauty spots of the celestial landscape. Not only are they impressive to observe, but they have led to remarkable advances in our knowledge. The measurement of the extent of the visible universe and an indication of its organization, together with intimations of its mass, population, and past duration, are among the contributions to astronomy and cosmogony that have been made chiefly through the study of star clusters. The researches have been descriptive, astrometric, photometric, spectroscopic, statistical, mathematical, and speculative—often complicated, and more often very tedious. In a three-page account of these ancient and instructive cluster systems, the reader can be and should be spared the details of method and the evidence of observatory labours. Perhaps the most important item will be the short bibliography, which will guide the reader who desires more information. The aim of the following treatment is a general survey of the subject and a statement of current results; we take up, successively, (1) introductory remarks on the frequency and variety of clusters,

(2) the naked-eye systems and their measurable motions, (3) classification and distribution, (4) the forms of globular clusters, (5) variable stars in clusters, (6) distances and dimensions, and (7) the rôle of clusters in the evolution of stars and galaxies.

1. **Introduction.**—The grouping and clustering of astronomical bodies are so common that we may infer from available observation that most of them are in close gravitational association. The earth-moon system, the sun and the planets, and the close double stars are examples of physically associated groups, probably all resulting from subdivision. Wide binary stars, typical star clusters, and star clouds are further examples of gravitational organization, but possibly they represent the accumulation of once isolated bodies and not the fission of originally larger masses. Organized systems smaller than any of these are the showers of meteors; and larger groups are the galaxies, and the clusters of "island universes."

It is not easy to draw a dividing line between multiple stars and star clusters. The brightest star, Sirius, is double; the nearest star, α Centauri, is triple; possibly Polaris is quadruple, and Castor is sextuple. The trapezium of the Orion Nebula, θ Orionis, is actually the many-starred nucleus of a widely spread system of stars. For the convenience of the present discussion we shall call the Ursa Major group of bright stars, the Great Bear, a cluster. All groups of equal or greater population will fall within the cluster category, up to the richest of globular clusters, where we shall limit the family, without including the spheroidal extra-galactic nebulae (which may be merely globular clusters of superior size), or the star clouds and the spiral nebulae.

It will be convenient to divide the star clusters into a globular class and a galactic class; the one is named from its form, the other from its apparent and real association with the Milky Way. The former can be limited fairly well to one hundred objects, only a dozen of which approach in structure, and in paucity of stars, the more open clusters of the galactic class; but the galactic clusters themselves are so varied in form, population, and angular and linear dimensions, that no distinct limits can be set, at least between them and the chance aggregations of stars in the Milky Way. A current compilation of well-defined galactic clusters, made at the Harvard Observatory, contains about 250 entries

2. **Conspicuous Star Clusters.**—The stellar groupings that have led in ancient and modern times to the establishment of constellations frequently bring together stars that are not actually associated in space. A few, however, involve bright stars that are physically allied—notably Orion, Ursa Major, Scorpio, and Perseus. Thus, five of the seven conspicuous stars of Ursa Major are now known to be closely alike in distance, in amount of motion, and in spectral class, and though they are widely separated in the sky, Sirius and other bright stars are also members of the same Ursa Major family. These stars move in parallel paths through space, and probably they have constituted a cluster throughout their whole past history as stars, and will continue to be associated in the future for a period indefinitely long. Ultimately, through encounters with other stars, the members of such groups may be diverted from essentially parallel motion, for they move through the highly populated regions of the Milky Way.

A number of the naked-eye stars in the constellation Orion also form a large loosely organized cluster, composed almost wholly of the very hot stars of spectral class B. There are similar large loosely defined groups of B stars in Vela, Centaurus, Scorpio and Perseus. In fact, J. C. Kapteyn's researches and the subsequent investigations by C. V. L. Charlier and Harlow Shapley have shown that these various groups of B stars all together form a larger system of which the total diameter is probably in excess of a thousand parsecs (a parsec is 3×10^{13} kilometers, approximately). This system of loose clusters, named the "local system" by Shapley, is known to contain a great number of stars besides those in the localized B type clusters; according to recent researches by F. H. Seares, it also includes the vast majority of all stars surrounding the sun. The local system is, in fact, rather in the nature of a star cloud, like those in the Milky Way, or like the Magellanic Clouds, and as such it need receive no further consideration in this discussion of star clusters.

Systems more definitely circumscribed than the constellations just named are the Hyades, the Pleiades, Coma Berenices, Praesepe, and the Double Cluster in Perseus. All these clusters are visible with the unaided eye, and for all of them the proper motions (angular speeds) have been studied in much detail. An investigation of the proper motions of the individual stars of a cluster leads to the discovery, first made for the Hyades by Lewis Boss, that the paths converge towards a common point (or diverge from one). The convergence is obviously a matter of perspective. When the convergent point is accurately determined, and the motion of one or more of the stars of the cluster in the line of sight has been determined spectroscopically, then we can determine with high accuracy the linear distance to the cluster and the actual speed of the stars. If V is the radial velocity of the star in kilometers per second, μ its proper motion in seconds of arc per year, and θ the angular distance from the star to the convergent point, then the distance in parsecs, R, is given by

$$R=0{\cdot}211\ V\tan\theta/\mu$$

and the velocity in space in kilometers per second is

$$v=V\sec\theta$$

When the velocities of several stars are measured spectroscopically, as is possible in the Hyades, mean values of V can be obtained, thus eliminating the effect of accidental errors and peculiar velocities, and the distances of the individual stars and of the cluster as a whole are determined with high precision

If its distance is known, a cluster can be dissected in detail. The candle power of its various stars is readily deduced from measures of apparent brightness. In the case of the Taurus cluster, the dispersion in luminosity is found to range over at least six stellar magnitudes, that is, a range in brightness of more than 250 to 1. Most of the members of the cluster lie within a sphere of 10 parsecs radius, the centre of which is about 42 parsecs distant from the sun.

In a similar way, but with less accuracy, the convergent point and distance of the Pleiades can be determined. There is good evidence also (from a study by A. Kohlschutter) that the stars of Praesepe move toward the same convergent point as those of the Hyades, and this affords a means of determining the distance of Praesepe. The radial velocities of several of the brighter stars in the double cluster in Perseus (h and χ Persei) have been shown by Mount Wilson observers to be about 40 km/sec; the proper motion of the double system is so small, however, that the convergent point and distance are as yet uncertainly determined

Frequently it has been suggested that certain stars move in paths parallel to the sun's motion in space, and that our system, therefore, is a member of an open star cluster. This matter has been especially investigated by W. J. Luyten, who finds no good evidence of solar companions, with the possible exception of the fifth magnitude star 46 Tauri. It may be suggested that the existence of planets around the sun argues against its membership in a star cluster, for the hypothetical ancient encounter with another star that gave rise to the planetary births would at the same time deflect the sun from its original path and detach it from the cluster to which it may once have belonged.

3. **Classification and Distribution of Clusters.**—Various classifications of clusters have been proposed, but because of the gradual transition from one form to another no classifying, beyond the major divisions of globular and galactic clusters, is much more than a working convenience. Recently, however, Shapley and Miss Sawyer have classified the globular clusters on the basis of central concentration, and R. Trumpler and Shapley have proposed simple classifications for the brighter galactic clusters on the basis of the spectral characteristics of their stars.

A typical globular cluster is an assemblage of scores of thousands of stars, perhaps hundreds of thousands. It is approximately circular in outline, strongly concentrated to the centre, and so remote in space that although actually of great dimensions it rarely exceeds the moon in angular size even when its most

outlying members are included. Its stars are normal giants and super-giants, as far as our present researches show, for dwarf stars of the sun's light and diameter would be unattainable with our present telescopic power when at the distance of the nearest globular cluster.

There is a general similarity among globular clusters in size, form, content and integrated brightness; but marked deviations from the average have been noted in the matter of compactness. Also, some globular systems, such as No. 19 of Messier's list and ω Centauri, are conspicuously elongated; Messier 62 is easily seen to be non-symmetrical, and a few systems are obviously deficient in giant stars. The new classification distributes the one hundred globular clusters into twelve approximately equal classes, Class I representing the highest concentration of the stars toward the centre, and Class XII the least. A study of the relation of the concentration classes to distribution in the sky, total brightness, number of stars, and ellipticity of apparent form shows no significant interdependence of these quantities; but it is probable that the classes are an indication of developmental age, and they should thus prove useful in studies of the linear diameters, the frequency of variable stars, and the deeper problems of the origin and life-history of stellar systems.

The galactic clusters, which are typically irregular in form, loosely organized, and composed of a few scores or a few hundreds of highly luminous stars, can be most conveniently placed in two classes (according to Shapley)—the Hyades type and the Pleiades type—either of which may be associated with star clouds or diffuse nebulosity. In the Hyades type we find some yellowish or reddish giant stars (spectral classes G, K, M), together with stars of the hotter spectral classes (B, A, F); whereas in the Pleiades type of cluster the cooler giant stars are lacking and all the cluster stars fall along the main sequence of spectral types which extends from the giant B and A stars down through the intermediate Classes F and G to the dwarfish red stars of Classes K and M. Trumpler has proposed some subdivisions of these two main types of galactic cluster.

There is as striking a difference between globular and galactic clusters in distribution over the sky as in population and compactness. With scarcely an exception the galactic clusters are scattered along the central line of the Milky Way; very rarely is one found more than ten degrees from the galactic circle. The globular clusters, on the other hand, are frequently found in high galactic latitudes, that is, angularly far from the Milky Way. As we approach the low galactic latitudes, however, they become more numerous, up to the very edges of the stream of Milky Way star clouds. But their number suddenly falls off near the central line of the Milky Way, so that only two or three are found along a central belt seven or eight degrees in width. It is just within this region devoid of globular clusters that the galactic clusters and rich star clouds are most numerous.

The contrasted distribution may be explained largely by the fact that globular clusters are, on the average, much more distant than the open groups, and that globular clusters in low galactic latitudes therefore may be obscured by intervening clouds of cosmic matter which lie beyond the galactic clusters of our catalogues.

The galactic star clusters are distributed throughout all longitudes along the Milky Way, whereas the globular clusters are highly concentrated in the constellations of Ophiuchus, Scorpio and Sagittarius. The same region of the sky is also very rich in remote variable stars, in novae, planetary nebulae and star clouds; it is a region of depth and heavy stellar population.

4. **The Forms of Globular Clusters.**—A deviation of the photographic image of a star cluster from circularity was first pointed out with certainty for a few globular clusters by S. I. Bailey in his study of Harvard photographs. Subsequent detailed counting of stars in globular clusters at the Mount Wilson Observatory by F. G. Pease, Shapley and others, showed that the lack of exact radial symmetry in the globular clusters is typical. Thorough investigations of this matter, mainly at the Mount Wilson and Harvard Observatories, led to the conclusion that the average globular cluster is flattened, as though by rotation or by dynamical encounter with other stellar systems. This flattening reveals itself through the elliptical form of the projected image. In a recent study at Harvard the ellipticities of the photographic images of about one-third of all globular clusters are satisfactorily estimated; in the most extreme cases the minor axis of the projected ellipse is but six- or seven-tenths of the major axis; but it is not possible to evaluate separately both the true flattening of a cluster and the inclination of its equatorial plane to the line of sight. The most we can say is that some globular clusters have equatorial diameters at least forty per cent greater than their polar diameters. In no cases do they appear to attain the high degree of flattening observed in spiral nebulae (*q.v.*) or in the Milky Way system itself.

Much work has been devoted to studies of the laws of the distribution of stars in globular clusters. Various formulae relating the number of stars per unit volume, N, with distance from centre of projected image, r, or with ρ, the distance from the cluster center, have been derived or assumed, and applied to published counts of stars. For instance,

$$N(\rho) = \frac{1}{\pi}\int_{\rho}^{R} \sqrt{(r^2-\rho^2)}\,\frac{d}{dr}\left(\frac{1}{r}\,\frac{dn}{dr}\right) dr$$

(E. C. Pickering, H. von Zeipel) where R is the radius of the cluster and n is the number of stars in the corresponding unit area of the projected image. Analogies with the kinetic theory of gases have encouraged some of these researches. No completely satisfactory representation of the observations has been found, which is not surprising because the data, with which comparison is made, are inherently faulty. The so-called Eberhard effect, intrinsic in almost all photographic work in crowded regions, vitiates the results because the photographic development is more thorough, and brings out fainter stars, at the edges of clusters than in the centre. Further, the available counts deal only with the few hundreds or few thousands of the super-giant stars of the globular clusters; the tens or hundreds of thousands of fainter stars cannot be considered in the theoretical investigations. In counting cluster stars there are also practical difficulties with varying photographic contrast, and with the serious effect on stellar magnitude of the curvature of telescopic fields. And finally, nearly all discussions of the problem heretofore have ignored the lack of radial symmetry.

In general, the frequency of giant stars, except near the centre, is (roughly) inversely proportional to the fourth power of the distance from the centre for most of the typical globular clusters; the laws of distribution of fainter stars are even less definitely known. Beyond this we cannot go at present.

The distribution of stars in galactic clusters is too varied for any general statement beyond noting a frequent centralization; probably the distribution is here not very significant because these loose and irregular systems have been much distorted by the perturbations of the galactic stars among which they move.

5. **Variable Stars in Clusters.**—After a few sporadic discoveries of variable stars in the globular clusters had been made, S. I. Bailey turned his attention to the problem in the last years of the 19th century, making use of photographs taken with the 13-in. and 24-in. refractors of the Harvard Observatory. Bailey's work revealed literally hundreds of variable stars in the score of clusters he closely examined. In some globular systems one star out of six, among the giant stars, proves to be periodically variable (*see* p. 334); whereas in other clusters of practically the same appearance, brightness and concentration, no variable stars are found. Bailey's work on the variable stars shows them to be typically of the short period Cepheid class; a few Cepheids with periods greater than one day were found among the stars of the clusters, and a few irregular variables, but the overwhelming majority belong to that subtype of Cepheid which is now known as the cluster type variable. In ω Centauri Bailey finds three subclasses of cluster type stars, distinguished by the shapes of the light curves and the lengths of the periods. The most common, subclass a, has a period of about thirteen hours on the average, and this type appears most commonly in other globular clusters. The median magnitudes of all the variables

in a given cluster are essentially the same, whatever the subtypes or the range of variation. The difference in the observed median from cluster to cluster is probably due wholly to the different distances, the median absolute luminosity thus being the same everywhere, and apparently a constant of nature peculiar to the cluster type Cepheid

In the galactic clusters there are as yet no known variable stars, the three or four possible cases on record being as readily attributed to the galactic foreground and background as to the cluster system itself.

Bailey's classical work on variable stars in clusters has recently been considerably extended through the discoveries and studies with large reflecting telescopes by Shapley and assistants at the Mount Wilson and Harvard Observatories, and by W. Baade and J Larink at the Bergedorf Observatory, Hamburg

Variable Stars

Name of cluster	Number of stars examined	Number of variables	Proportion variable
47 Tucanae	2,000	6	0·003
Dunlop 62	675	14	·021
Messier 79	200	5	·025
ω Centauri	3,000	128	·043
Messier 3	900	162	·180
Messier 5	900	85	·094
Messier 13	1,000	4	·004
Messier 62	960	26	·027
Messier 22	1,550	16	·010
Messier 15	900	51	·057

6 **The Distances of Globular Clusters.**—The relation between apparent brightness and period for Cepheids in the Small Magellanic Cloud, found by Miss Henrietta Leavitt, was generalized by Shapley with the aid of galactic Cepheids and the variables of the globular clusters The "period-luminosity" curve, which relates the absolute magnitude (intrinsic luminosity) of the Cepheid variable to the logarithm of its period, was thus derived. The zero point of the curve was fixed with the aid of the nearer galactic Cepheid variables, for which the distances and absolute magnitudes were determined from studies of their motions

The period-luminosity curve permits the determination of the intrinsic luminosity, and therefore of the distance, of any Cepheid variable when the period of its variation and its apparent brightness are measured. With its use, not only are the distances and distribution in space of the galactic Cepheids readily deduced, but also, of more importance, the distances of all the globular clusters, or other stellar systems, which contain Cepheid variables are simply derived. When the distances of clusters containing Cepheids have been obtained, the distances can be inferred also for the clusters devoid of variables, because of the apparently inherent similarity of all globular systems in linear size, total luminosity, and in the real brightness of their most luminous stars. The observed angular sizes and apparent magnitudes thus become indicators of distance Applications of these principles by Shapley (1917) (later revised by Shapley and Miss Sawyer [1928]), have led to a determination of the distances and distribution in space of all known globular clusters. Uncertainties may arise through the absorption of light in space, the dissimilarity of globular clusters in the characteristics used in estimating distances, the errors in the apparent magnitudes of the variable stars and other stars in the faint clusters which are hard to measure, and, finally, through error in the determination of the zero point of the period-luminosity curve. The last contributes the most serious possibility of systematic error, but the current work at various observatories on the distances and luminosities of the brighter galactic Cepheids will soon remove the difficulty, and provide accurate calibration of the period-luminosity curve.

The studies of the colours of stars in distant clusters have shown conclusively that no absorption of light in space that is proportional to the wave length of the light is measurable, except in localized regions; and the inference is probably safe that except in special nebulous regions space is clear of matter that seriously obstructs or scatters light.

The studies of variable stars in distant clusters, using photographic plates sensitive to blue and yellow light, led to the measurement with surprising accuracy of the relative velocity of light of different wave lengths. It was found that light waves differing twenty-five per cent in length travel in space with identical velocity, the probable error of the determination not exceeding one part in ten thousand million. This accuracy is possible solely because of the enormous distances of globular clusters.

Though subject to the uncertainties mentioned above, the distances of the clusters, derived as indicated, are now generally accepted. The one hundred known systems range in distance from 15,000 to nearly 200,000 light years. Their concentration to the Milky Way indicates that they are a part of the general galactic system, and in fact their distribution has been generally taken to outline the form and extent of the Galaxy The diameter of the system of globular clusters is of the order of two hundred thousand light years; the centre of the system lies in right ascension $17^h 30^m$, south declination $33°$, near the junction of the constellations Ophiuchus, Scorpio, and Sagittarius. The distance from the earth to the centre of this system is of the order of fifty thousand light years.

The linear diameter of the average globular cluster is between one and two hundred light years, not counting its most outlying members The density of stars, therefore, near the centre is uncommonly high compared with the density in the solar neighbourhood, for a cluster's population probably exceeds 100,000.

For the galactic clusters, the distances are not as yet satisfactorily determined The absence of Cepheid variables, and the irregularity and diversity of form and population, leave us with very indirect methods of estimating their distances or the luminosities of their stars From preliminary results we know that most galactic clusters are but a few hundred or a few thousand light years distant. It is probable that the more distant galactic clusters are lost to observation through being indistinguishable in the rich Milky Way star clouds

The velocities of a number of the globular clusters, measured for the most part at the Lowell Observatory by V. M. Slipher, lie mainly between one hundred and three hundred kilometers a second—much higher than the velocities of most classes of stars. The proper motions are as yet practically unattainable because of the great distances of the clusters. The radial velocities of galactic clusters, so far as determined, are of very moderate amount, and the motions appear to be parallel to the galactic plane.

7. **The Rôle of Clusters in Cosmogony.**—The centre of the system of globular clusters can be accepted in the first approximation as the centre of the Galaxy; and the extent of the system of clusters indicates at least a minimum for the size of the galactic system. It has been shown in recent years that the same centre is indicated, but with less certainty, by other highly luminous objects—the novae, the galactic Cepheids, the planetary nebulae, as well as by the distribution and density of galactic star clouds. Furthermore, there is evidence from the motions of stars in the solar neighbourhood that the whole galactic system rotates about this same centre in the southern Milky Way. Apparently, therefore, the globular clusters lead to a conception of an enormously large stellar system in which the solar system is eccentrically situated. The condensation of stars in the solar neighbourhood appears to indicate only that the sun is near the centre of a local cloud or system.

The total number of luminous stars in the Galaxy is probably not less than fifty thousand million. Of this number a relatively small proportion is involved in the now recognized globular and galactic clusters. But there is some evidence supporting the hypothesis that the star clouds throughout the Milky Way are largely composed of disintegrating clusters. The possibility that the galactic clusters represent the remnants of globular systems that have been dragged into the Milky Way star fields and dismembered, is advocated by Shapley, P. ten Bruggencate, and others. J. H. Jeans suggests that the globular clusters may represent groups that have escaped from the Milky Way, or at least are keeping clear of its disintegrating tendencies. The solution of the problem does not seem hopeless, given enough observations and

EXAMPLES OF GLOBULAR AND GALACTIC STAR CLUSTERS

1. Globular star cluster, M 13, in Hercules. 2. Small Magellanic Cloud, below, and globular cluster 47 Tucanae, above. 3. Double star cluster in Perseus. 4. Section of the southern Milky Way showing the globular cluster (ω) Centauri in the upper left-hand corner. The dark nebula in the centre is the "Coal Sack." Directly north-west of the "Coal Sack" and consisting of four stars, is the constellation of the Southern Cross

thought; and at any rate the various clusters seem to be intimately connected with the star clouds of the Milky Way and with the genesis and future development of this largest of all known galaxies.

The most important prooiems immediately ahead of the investigator of star clusters appear to be (1) the question of the relative frequency of dwarf stars, to be answered by study of the faintest attainable stars in the nearest globular star clusters with the greatest reflecting telescopes; (2) the stability of globular clusters in traversing stellar and nebular fields (a problem already partially solved by Jeans); (3) the abnormal and connectant type of globular clusters; (4) the spectral composition of clusters, compared with that of galactic star fields and the Magellanic Clouds; (5) further study from many standpoints of the variable stars in clusters. These problems indicate the many points where star cluster investigations touch on questions of stellar evolution as well as on the measurement of the Galaxy.

STAR-FISH. This name covers three classes of the echinoderms, namely sea-stars or Asteroidea, brittle-stars or Ophiuroidea, and feather-stars or unstalked Crinoidea. (*See* ECHINODERMA, figs. 1, 2 and 4.) The Asteroidea and Ophiuroidea are free-moving and live mouth downwards like sea-urchins; thus they differ from Crinoidea, which are normally attached by a stalk, and live mouth upwards. (*See* ECHINODERMA.)

The Sea-stars, to which the name "star-fish" is often restricted, include many different forms, but the common cross-fish or five-finger (*Asterias rubens*) of British seas, or *A. vulgaris* from America, may be taken as typical. The animal consists of a central body and five (occasionally 4, 6 or 7) arms, not clearly marked off from it. The upper surface is covered with a leathery skin, in which are little plates of carbonate of lime, many bearing prickles and small pincer-like pedicellariae. (*Cf.* SEA-URCHIN.) For further details of structure, *see* ECHINODERMA. A sea-star can crawl over any surface by means of its sucking-feet, and can squeeze its supple body through incredibly narrow crevices. The rate of progress is about 6 in. a minute. The but-thorn (*Astropecten*) has no suckers, and creeps over hard sand on its pointed podia. Cushion-stars are stiff, swollen, five-sided forms. The smallest British sea-star (*Asterina gibbosa*) is of this shape; its near relation, the bird's-foot star (*Palmipes*) is flat and thin. Sun-stars (*Solaster*) are remarkable for the number of arms, which may exceed 30.

Sea-stars are the scavengers of the sea, but unfortunately do not confine their attentions to decaying matter; they eat oysters, clams, mussels, barnacles, sea-snails, worms, crustaceans and even smaller sea-stars. No less than 42,000 bushels of sea-stars were removed from the oyster-beds of Connecticut in a single year; they had worked damage to the amount of $631,500. The simplest way in which a sea-star eats is by using its podia to pass small bits of food into the stomach, and ejecting the refuse through the mouth. But when the food is large, the sea-star finds it more convenient to turn its stomach inside out, and wrap it round the prey, which is then digested quickly and the stomach withdrawn again. In attacking oysters and similar bivalves, the sea-star first has to open them; this it does by fixing the suckers of one or two arms to one valve, and those of the opposite arms to the other, while it may get a purchase by also holding on to neighbouring objects. It then begins to straighten out its rays. The oyster can withstand a strong pull, but not a long pull, and the sea-star does not hurry. At last the oyster gives way, and the sea-star has its reward; its companions often join in, and a whole rolling ball of them may be seen interlaced round half-digested molluscs. Sea-stars begin to eat voraciously when quite young; one less than $\frac{1}{8}$ in. across ate over 50 young clams of half that length in six days. A sea-star may become sexually mature in less than a year, then producing many thousands of young. Increase is kept in check by many causes. The free-swimming larvae are swallowed in millions by fish. When they settle down on sea-weed their bright colours attract eels and many small fishes. Later in life they are attacked by parasites, while those that stray into shallow water are eaten by gulls, crows and even foxes. Freshets and cold currents are also destructive. Probably the best way in which man can keep down the numbers is by dredging the sea-weed a month after midsummer when covered with young; a single cartload thrown on shore would capture many millions. At a later stage tangles of hemp or cotton waste may be dragged over oyster-beds, when the sea-stars will cling to them by their pedicellariae. They make excellent manure. Fishermen who catch them often tear them in half and throw them back into the sea. Some of these mutilated animals may, however, grow fresh arms, and thus one may find a sea-star with one large arm and four small ones, the whole shaped like a comet.

The Brittle-stars or Ophiuroidea ("snake-tails") differ from sea-stars in moving almost entirely by means of their arms. (*See* ECHINODERMA, fig. 2.) Thus the arms are sharply marked off from the disc-like body, to which digestive and generative organs are confined. Brittle-stars proper have long wriggling arms, fringed with prickles, with which they can progress more than two yards a minute. If seized, they break off their arms, which continue breaking into smaller pieces; but the body soon grows new ones. Sand-stars have shorter, stouter arms, with prickles closely pressed to the sides; they progress by a rowing movement. Sand-stars and brittle-stars abound in the shallow waters of all seas, especially in the tropics. By constantly sweeping their arms over the sea-floor they gather in minute animals as food. They eat the bait of fishermen, and their fish as well if they find any already dead; but they are themselves a food of many fishes, notably cod. Basket-fish or medusa-heads are ophiuroids whose arms branch several times, their ends curling and interlacing round some marine object. They live in deeper water and are often brought up clinging to fishermen's lines.

The Feather-stars (Unstalked Crinoidea) are distinguished as Comatulida ("hair-stars") from various other crinoids that have at earlier periods of the world's history lost their stem. A typical form is the rosy feather-star (*Antedon bifida*). (*See* ECHINODERMA, fig. 4.) The stalk is not really absent, but reduced to a knob, from which spring numerous hooked tendrils (cirri); by these the animal clings to some object on the sea-bottom. From the body stretch five arms, each bifid (in other species they may fork more than once) and fringed with small branches (pinnules) giving a feathery appearance. Along these arms and pinnules, grooves pass from the central upturned mouth (ECHINODERMA, fig. 7), and the minute hair-like cilia that line them constantly sweep towards the mouth a stream of water, from the microscopic organisms in which the crinoid extracts nourishment. *Antedon* crawls by pulling and pushing with its arms, and swims, or rather treads water, by raising and depressing alternate branches. The ancestors of the feather-stars in the Jurassic period still had a stem in the adult. Since that period feather-stars have increased in number and variety, so that to-day they occur in all salt seas at all depths, often in enormous quantities, and are classified in 98 genera. (F. A. B.)

BIBLIOGRAPHY.—For special works with bibl., *see* ECHINODERMA.

STARGARD, a town in the Prussian province of Pomerania, situated on the left bank of the navigable Ihna, 20 m E. of Stettin on the railway to Danzig and at the junction of lines to Posen, Schneidemühl and Custrin. Pop (1925) 32,575. Stargard, mentioned as having been destroyed by the Poles in 1120, received civic rights in 1229, and became the capital of eastern Pomerania. As a Hanseatic town it enjoyed considerable commercial prosperity, but it had also to undergo siege and capture in the middle ages and during the Thirty Years' War.

STARK, JAMES (1794–1859), British painter, was born in Norwich on Nov. 19, 1794, and at the age of seventeen was articled to John Crome for three years. He died in London on March 24, 1859 Between 1831 and 1859 most of his pictures were shown at the Royal Academy. He undertook in 1827 the publication of a work on *The Scenery of the Rivers of Norfolk,* which was completed seven years later; the illustrations he prepared for it have much topographical and artistic interest. His painting "The Valley of the Yare," is in the National Gallery of British Art

STARK, JOHANNES (1874–), German physicist, was born April 15, 1874 at Schichenhof in Bavaria and studied at the University of Munich. In 1900 he became an assistant at the University of Gottingen. He went as professor in 1907 to the Technische Hochschule at Aix-la-Chapelle, in 1917 to Greifswald and in 1920 to Würzburg; he retired in 1922. Stark devoted himself principally to the study of the modern theory of radiation and the atomic theory. He discovered the Doppler effect in parallel rays, for which the Vienna Academy awarded him the Baumgartner Prize. Later he discovered the Stark effect, named after him, and in 1919 was awarded the Nobel Prize for Physics. He wrote numerous essays on physical problems, including the *Prinzipien der Atomdynamik,* in 3 parts (1910–5); *Die elektrischen Quanten, Die elektrische Strahlung, Die Elektrizität in Gasen* (1902) and *Die Dissociierung und Umwandlung chemischer Atome* (1903). He was the founder of the *Jahrbuch der Radioaktivität und Elektronik* (1904), which he edited until 1919.

STARK, JOHN (1728–1822), American soldier, was born at Nutfield, now Londonderry, N. H., on Aug. 28, 1728. During the Seven Years' War he served under Robert Rogers, first as a lieutenant and later as a captain. At the beginning of the Revolutionary War he raised a regiment and as colonel did good service in the Battle of Bunker Hill, the Canadian expedition, and Washington's New Jersey campaign in the winter of 1776–77. In March 1777 he resigned his commission. Later in the year, he was placed in command, with the rank of brigadier general of militia, of a force of militiamen, with whom, on Aug. 16, near Bennington, Vt., he defeated two detachments of Burgoyne's army. For this victory, which did much to bring about the capitulation of Gen Burgoyne, Stark received a commission as brigadier general in the Continental army (Oct 4, 1777) He took part in the operations about Saratoga, and for a short time was commander of the northern department. In Sept. 1783 he was breveted major general. He died at Manchester, N H., on May 8, 1822.

See *Memoir and Official Correspondence of General John Stark* (1860) by his grandson Caleb Stark.

STARK EFFECT: *see* QUANTUM THEORY; LIGHT.

STARLEY, JAMES (1830–1881), British inventor, the son of a farmer, was baptized at Albourne, Sussex, on June 13, 1830. In 1857 he started in Coventry the manufacture of the "European" and other sewing machines from his patents. In 1868 he began the manufacture after a Paris model and at first for French use, of bicycles, several of the earliest suggested improvements being Starley's. A number of firms were soon devoting themselves exclusively to the manufacture of bicycles, and for one of these Starley designed the Coventry tricycle. As it was harder to propel than the bicycle, he invented the balance gear, and applied it in the Salvo tricycle. Starley died on June 17, 1881. His nephew, J. K. Starley, patented the tangent wheel in 1874.

STARLING, ERNEST HENRY, F.R S. (1866–1927), English physiologist, eldest son of H. H. Starling, Clerk of the Crown at Bombay, was born in London, 1866 Educated at King's College School; entered Guy's Hospital in 1882 and graduated M.D. in 1890. He never practised as a physician and in the same year he was appointed lecturer in physiology at Guy's. In 1900 he became Jodrell professor of physiology at University College, London, where he continued to work throughout his life, although, in 1922, he retired from the Jodrell Chair and was appointed Foulerton research professor of the Royal Society.

Starling was one of the foremost physiologists of his age. The subjects for investigation which particularly attracted him were those physiological processes which seemed capable of interpretation in terms of chemistry and physics. The conditions determining transudation from the vessels and lymph flow occupied his attention for some years and he showed that the hydrostatic and osmotic pressures within the vessels supplied the balance of force necessary to explain the hitherto perplexing experimental facts. His researches on the movements of the intestines, undertaken in conjunction with Bayliss (*q v*) demonstrated the neuro-muscular mechanisms involved and reduced the previous chaos to order Their discovery of "secretin" not only laid bare the way in which the secretion of the pancreas was called forth and adjusted, but stimulated further research on the chemical integration of the body functions, since so profitable. By ingenious methods of experimentation he was successful in maintaining the mammalian kidney, isolated from all connection with the body, in a state of functional activity and thereby to bring to light new and fundamental facts concerning renal secretion. Starling's most important researches were, however, those dealing with the heart and circulation. Together with many other important discoveries on the physiology of the circulation, he demonstrated the mechanism by which the heart is able to automatically increase the energy of each contraction in proportion to the mechanical demand made upon it and, apart from the nervous system, to adapt its work in accordance with the needs of the body No one physiologist has so greatly advanced knowledge of the heart's action since the discovery of the circulation by Harvey 300 years ago

During the World War, he became director of research at the R A M.C. College and engaged in devising defensive methods against poison gas. Subsequently, 1917–19, Starling rendered valuable national service as chairman of the Royal Society Food Committee, scientific adviser to the Ministry of Food and British scientific delegate on the Inter-Allied Food Commission.

STARLING (*Sturnus vulgaris*), a bird common throughout northern Europe and Asia and also found in India About the size of the thrush, the starling has a plumage of black, beautifully glossed with purple, green and steel-blue and having each feather tipped with buff. The starling is an omnivorous feeder, but, where numerous (as in Britain), it must undoubtedly be numbered among the injurious species. It gathers in enormous flocks in the autumn to roost in reed-beds, and such a flock on the wing is a memorable sight, their simultaneous turns in the air being very remarkable. Of late years, it has taken to roosting in increasing numbers on large buildings in London and other towns The song of the male is cheerful and varied, if not very beautiful, and the bird's disposition is bustling and lively. It nests in holes in trees, which it frequently appropriates from a woodpecker, or in buildings. The eggs, four to seven in number, are a pale blue-green. As the young grow, they become extremely noisy. The starling was introduced into New York city in 1890. It spread rapidly in New York and adjoining States.

It has caused a decrease in many native hole-breeding birds by usurping the available nest sites. Allied species occur in the Mediterranean, Kashmir, Persia and Armenia.

The related genus *Pastor* includes the beautiful rose-coloured starling (*P. roseus*), a bird of irregular and erratic habits, arriving in incredible numbers in unexpected places to breed—usually in a district where locusts are becoming or have become excessively abundant. The plumage is rose-pink and black.

STARNBERG, a village and climatic health resort of Germany, in the republic of Bavaria, on the Starnberger See, 16 m. S. from Munich by rail Pop. (1925) 4,838. It has an old castle (now government offices). The Starnberger See (or Würmsee) is a lake with a length of 12 m., a breadth of 3 m., and covering 23

sq.m. Its greatest depth is about 400 ft. On the Roseninsel, an island in the lake, remains of lake dwellings were found.

See Ule, *Der Würmsel in Oberbayern* (Leipzig, 1901).

STAR-NOSED MOLE (*Condylura cristata*), a North American species. In habits it resembles the European mole, but is distinguished by the presence of a ring of tentacles, probably tactile, round the nostrils. (*See* INSECTIVORA.)

STARODUB, a town of Russia in the Bryansk province in 52° 35′ N., 32° 45′ E. It is the terminus of a branch railway, and three telegraph lines radiate from it. Pop. (1926) 10,919. Russian princes contended with one another for it in the 11th and 12th centuries. It was destroyed by the Mongols in the 13th century. In the 15th and 16th centuries the Russians and Lithuanians struggled for it; it became a Polish stronghold in the 17th century, but was handed over to Russia in 1686.

STARVATION, the state of being deprived of the essentials of nutrition, particularly of food (*see* HUNGER AND THIRST).

In starvation those tissues which are of the greatest importance to the economy are nourished at the expense of less important tissues. Thus the brain and spinal cord lose only 3 per cent of their weight in a hunger period during which fat loses 96 per cent. From the behaviour of the respiratory quotient in starvation it is clear that the wastage of muscle and other proteins is due to endeavours to keep up the body temperature at its normal level. Experimental starvation, even though food be entirely withheld is not accompanied by any great alteration in body temperature until starvation has been going on for perhaps three weeks.

STAS, JEAN SERVAIS (1813–1891), Belgian chemist, was born at Louvain on Aug. 21, 1813. He first studied medicine, and then worked in the Paris laboratory of J. B. A. Dumas (*q.v.*) whom he assisted in the redetermination of the atomic weight of carbon and in other work. From 1840 to about 1865 he was professor of chemistry at the École Royale Militaire at Brussels. He died at Brussels on Dec. 13, 1891.

Stas's name is best known for his determination of the atomic weights (*q.v.*) of a number of the more important elements. His work in this field, for which the Royal Society awarded him a Davy medal in 1885, was marked by extreme care. In connection with a poisoning case in 1850, Stas worked out a method for the detection of the vegetable alkaloids, which, modified by Friedrich Julius Otto (1809–1870), professor of chemistry at Brunswick, has been widely used by toxicologists as the Stas-Otto process.

Stas' papers on atomic weights were collected in *Recherches sur les Rapports réciproques des Prids Atomiques* and in *Nouvelles Recherches sur les Lois des Proportions Chemiques.*

STASINUS, of Cyprus, according to some ancient authorities the author of the *Cypria* (in 11 books), one of the poems belonging to the epic cycle. Others ascribed it to Hegesias of Salamis or even to Homer himself. The *Cypria* contains an account of the events leading up to the Trojan war, such as the judgment of Paris and the rape of Helen. It is probable that the list of the Trojans and their allies (*Iliad,* ii. 816–876), which formed an appendix to the catalogue of the Greek ships, is abridged from that in the *Cypria.* Proclus, in his *Chrestomathia* gave an outline of the poem (preserved in Photius, *cod.* 239).

See F. G. Welcker, *Der epische Cyclus* (1862); D. B. Monro, Appendix to his edition of *Odyssey,* xiii.–xxiv. (1901); T. W. Allen, "The Epic Cycle," in *Classical Quarterly* (Jan. 1908, *sqq.*); and CYCLE.

STASSFURT, a town in the Prussian province of Saxony, and one of the chief seats of the German salt-producing industry; on the river Bode, 20 m. S.W. of Magdeburg by rail to Aschersleben. Pop. (1925) 16,136. The systematic exploitation of the salt-beds to which the town owes its prosperity, dates from 1856 only. Besides the rock-salt, the saline deposits yield deliquescent salts and other saline products, which have encouraged the foundation of numerous chemical factories. For about 50 years prior to the World War the bulk of the potash used throughout the world originated in the Stassfurt mines. The deposit underlies an area of about 100 sq.m. and is the largest body of soluble potash known. Production continues to be heavy, although Germany's monopoly is no longer complete.

STATE: *see* SOVEREIGNTY.

STATE, ACT OF, the plea of "act of state" in English law means primarily a defence raised by the Crown on behalf of a servant of the Crown, who is sued in the English courts for some wrongful act ratified by the Crown. In this sense the plea is not recognized by the English courts who, in rejecting it, have uniformly held that, as the King cannot do a wrong so also "it follows that the King cannot authorize a wrong." The only exception to this rule is in the case of a wrongful act done to an alien who, in such a case cannot sue (*Buron* v. *Denman* [1848] 2 Ex. 167) if the act was done outside British territory and was ratified by the Crown, but it has recently been held in *Johnstone* v. *Pedlar* 90 L.J.P.C. 181 that if the act complained of was done to him in British territory he has the same right to sue as a British subject and the defence of "act of State" is, in that case, equally inapplicable. But the term is also used in another and less questionable sense. It will be entertained by English Courts where the acts in respect of which an action is brought are "transactions of independent States between each other," such as those arising out of the execution, or non-execution, of a treaty, the succession of the Crown to a foreign territory by cession or conquest, and the like. For example, a concession granted by the chief of native territory is not enforceable whether by Petition of Right or otherwise in British Courts by the grantees against the Crown, on succeeding to the territory by annexation (*Cook* v. *Sprigg* [1897] A.C. 572). So too the contractual obligations incurred, whether towards a British subject or an alien, by a foreign state are not binding on the Crown, after its conquest and annexation by the Crown, unless the Crown expressly elects to adopt them (*West Rand Gold Mining Co.* v. *the King* [1905] 74 L.J.K.B. 753); for annexation is an "act of State" of an international character. In such cases the title of the subject has originated with a foreign Government, not with the Crown. If the contract or concession in question had originally been made by the Crown itself, it would be another matter. Even in the case of a British Protectorate the Crown may plead "act of State" as a defence to claims in respect of expropriation of native territory because the Crown in such a case is acting in territory which is not British (*see* the recent case of *Sobhuza II.* v. *Miller* [1926] A.C. 518). So too claims arising under a treaty are not enforceable against the Crown unless and until the Treaty, which is an international act, becomes part of English municipal law by being incorporated in a statute. The negotiation of the Treaty is an "act of State" into which, and its meaning, the Courts cannot enquire. In this sense the declaration of war and the making of peace by the Sovereign is also an act of State. As Lord Somer put it in *Johnstone* v. *Pedlar* (Op. cit. at p. 794) "Municipal Courts do not take it upon themselves to review the dealings of State with State and Sovereign with Sovereign." On the other hand the mere fact that some act, wrongful *per se* in English law, was done in execution, or alleged execution, of a treaty made by the Crown against the person or property of a British subject is a defence that would never be entertained by the courts in action against a servant of the Crown, for, while a treaty cannot confer new rights, enforceable at law, upon a British subject, neither can it deprive him of any of his existing rights under English law. This was specifically laid down in *Walker* v. *Baird* [1892] A C. 491 where in an action for trespass an officer of the Crown put in the plea of "Act of State" in that he was acting in the execution of a Convention with the French Government.

STATE, DEPARTMENT OF: *see* GOVERNMENT DEPARTMENTS.

STATEN ISLAND, an island constituting the borough of Richmond, New York city, and Richmond county, the southernmost of the counties of the State of New York. It is separated from Long island on the east by the Narrows which connects upper and lower New York bay, from New Jersey on the north by the narrow channel of Kill van Kull which connects New York bay with Newark bay; and from New Jersey on the west by the narrow channel of Arthur Kill. On its south-east coast are lower

New York, Raritan and Prince's bays, Great Kills, and the Atlantic ocean.

Triangular in shape, it is 13½m long from north-east to south-west, has a maximum width of nearly 8m at its north end, and has an area of 57sq. miles. The north-east quarter is broken by two ranges of hills having a precipitous east slope and rising to a maximum height of about 400ft, 1m inland from the Narrows; but on the west and south the hills fall gently to the coastal plain, which, occupying the greater part of the island, is broken only by low morainal ridges and terminates in salt marshes along much of the west coast. There are many species of forest trees and more than 1,300 species of flowering plants and ferns.

The population in 1910 was 85,969; in 1920, 116,531. The north shore, including New Brighton, West New Brighton and Port Richmond, is largely given over to industrial development. In 1927 the local chamber of commerce listed 252 industrial establishments, employing 20,320 persons, with a capital investment of more than $93,000,000, and a product valued at $103,000,000. There are shipyards, bakeries, lumber mills, printing and publishing houses, and factories for the manufacturing of clothing, soap, linoleum, fertilizer, fireworks and other products. The chief residential communities lie along the easterly shore, from St George south to Ft Wadsworth. Tottenville, on the south-west tip of the island, is both a residential and industrial district. South and Midland beaches below the Narrows are popular seaside resorts.

The Staten Island Rapid Transit Railway furnishes electrified passenger service along the north and easterly shores. The north shore branch of this railroad, with a terminal at St. George, is the New York terminus of the Baltimore and Ohio Railroad for the handling of freight The island is connected by ferry with the boroughs of Manhattan and of Brooklyn, and vehicular bridges, completed in 1928, connect the south shore with Perth Amboy (N J.) and Howland Hook, Staten island, with Elizabeth (N J) A third bridge, connecting the north shore with Bayonne (N J), is scheduled for completion in 1932; until that date ferries will continue to operate between these two points The island has 21 deep-water steamship piers, 1,200ft in length, equipped with modern freight handling devices, and within the free lighterage district of New York city. In March 1929 steps were taken for the construction of a tunnel at the Narrows to connect the island with Brooklyn

When discovered by Europeans, Staten island was occupied by the Aquehonga Indians, a branch of the Raritans Several Indian burying-grounds and many Indian relics, including a stone head with human features, have been found here In 1630 the Dutch West India Company granted the island to Michael Pauw as a part of his patroonship of Pavonia, but Pauw sold his title back to the company without establishing a settlement and in 1636 a portion of it was regranted to David Pietersen de Vries, the remainder being erected into a patroonship and granted to Cornelis Melyn In 1641 de Vries established a settlement at Oude Dorp (Old Town), near South Beach, but after its destruction by the Indians in 1655 it was abandoned In 1658 a company of Waldenses settled at Stony Brook, about 2m W of the ruins of Oude Dorp, and this was the principal village for many years.

In 1664 when the duke of York became proprietor of the newly erected province of New York he granted Berkeley and Carteret all that portion of his province which lay west of the Hudson river, thus making Staten island a part of New Jersey. In 1668, however, the duke decided that all islands within New York bay which could be circumnavigated in 24 hours should be adjudged to New York. Capt. Christopher Billopp making the trip within the time limit, he was granted 1,163ac. of the south end of the island which became the manor of Bentley. The manor-house, built about this time, is still standing in the village of Tottenville. In this house Lord Howe on Sept. 11, 1776, held a peace conference with Benjamin Franklin, John Adams and Edward Rutledge representing the Continental Congress From July 3, 1777, until the close of the Revolutionary War, Staten island was held by the British In the War of 1812 Ft. Richmond was built at the Narrows and Ft. Tompkins in the rear of it The Federal Government bought the site in 1847 and after destroying the old forts began the erection of the present Ft Wadsworth and Tompkins, which constitutes one of New York's strongest defences. In 1898 Staten island became the borough of Richmond in Greater New York.

See J. J. Clute, *Annals of Staten Island* (1877); R. M Bayles, *History of Richmond County* (1887); and I. K. Morris, *Memorial History of Staten Island* (1898–1900).

STATE RIGHTS, a term used generally in political science to denote those Governmental rights which belong to the individual States of a Federal union, there being a certain sphere of authority in which these individual States may act without interference from the central Government Thus in the United States there were certain rights reserved to themselves by the States when forming the union under the Constitution of 1787. These rights the central Government is by fundamental law bound to respect, and they can be reduced only by amendment to the Constitution For 1,000 years the various German States were so jealous of any curtailment of their individual rights as to prevent the formation of an efficient Federal Government In Federal unions, such as Mexico and Brazil, where a central authority existed first and created the States, the belief in State rights is much weaker than it is in unions composed of originally independent States. The rights of a State are said to be delegated when, as in Mexico, Brazil and Colombia, the Constitution is created by a central national authority which also makes the States; State rights are residuary when independent States unite to delegate by a constitution certain powers to a central Government, as in the case of the United States, Switzerland and, until 1905, Sweden-Norway. History shows that States forming unions of the second class are certain in aftertime to deny or assert that the sovereignty of the State is one of the rights reserved, according as the State belongs to a stronger or weaker section or faction; State sovereignty being the defence of the weaker State or faction, and being denied by the stronger group of States which controls the Government and which asserts that a new sovereign State was created by a union of the former independent ones This dispute is usually ended by civil war and the destruction of State sovereignty The evolution of State rights as shown in the history of the United States is typical Thirteen independent States formed a Union in 1787 under a Constitution reserving certain rights to the States. The sphere of the State authority embraced most of the powers of government, except, for instance, those relating to foreign affairs, army and navy, interstate commerce, coinage and the tariff; the powers of the central Government were specified in the fundamental law Most of the States claimed at one time or another that sovereignty was one of the reserved rights of the States and on this theory the Southern States acted in the secession in 1861 The war that resulted destroyed all claims of State sovereignty The other rights of the States consisted of those not delegated to the central Government or forbidden to the States by the Constitution In case of doubt the presumption was in favour of the State Since the beginning, however, the central Government has gained strength at the expense of the States, seldom by direct usurpation (except during the Civil War and Reconstruction, 1861–76), but indirectly through use and custom, as the country and people developed and new conditions of government arose The field of State rights has not increased, while centralization has slowly but surely taken place. The central authority in the United States, formerly affecting the average citizen but little, now touches him in many of the activities of life and sometimes intrudes even into the domain of local self-government The history of the decay of State rights makes it seem doubtful if the Federal form of government is a permanent one, or is only a transient form between independent State Governments or loose confederacies and a centralized national Government.

Burgess, *Political Science and Comparative Constitutional Law* (1895); Woodrow Wilson, *The State* (1900 and later eds); A. H. Stephens, *Constitutional View of the War Between the States* (Philadelphia, 1868–70); A. L. Lowell, *Governments and Parties in Continental Europe* (Boston, 1896); and H. P. Judson, *Our Federal Republic* (1925).

STATE'S EVIDENCE: *see* KING'S EVIDENCE.

STATES-GENERAL, the English translation of (1) the *états-généraux* of France and (2) the *staten-generaal* of the Dutch Netherlands. The name in both cases signifies the assembly of the estates of the realm, as distinct from provincial assemblies of estates; it is thus the equivalent of the English parliament, of the Cortes in Spain, or the diet of the Holy Roman Empire, which the states-general resembled in their original constitution.

In France the states-general were first summoned, in 1302, by Philip IV. for the purpose of giving him moral support in his quarrel with Pope Boniface VIII. They consisted of representatives of the three orders of clergy, nobles and commons (*tiers état,* third estate), an arrangement which survived to the end, though their composition, as well as their effective powers varied greatly at different times. For various reasons (notably the Hundred Years' War and the religious wars of the 16th century) they never secured the power over taxation and legislation early obtained by the English parliament, and after 1614 they were never summoned until 1789, when they transformed themselves into the National Constituent Assembly. This Assembly consisted of the representatives of the three orders sitting together, but the states-general had ceased to exist (*see* FRANCE: *History*).

In the Netherlands the convocation of the states-general, consisting of delegates from the provincial estates, dates from about the middle of the 15th century, under the rule of the dukes of Burgundy. The name was transferred, after the separation of the northern Netherlands from the Spanish dominions, to the representatives elected by the seven sovereign provincial estates for the general government of the United Provinces. The states-general, in which the voting was by provinces (each province having one vote) was established from 1593 at The Hague. The states-general came to an end after the revolution in 1795, with the convocation of the National Assembly (March 1, 1796). (*See* HOLLAND: *History.*)

STATES OF THE CHURCH or **PAPAL STATES,** that portion of central Italy which, previous to the unification of the kingdom, was under the direct government of the see of Rome. Their area in 1859 was 16,000·8 sq.m.; their population in 1853 numbered 3,124,758.

With the exception of Benevento, surrounded by the Neapolitan province of Principato Ulteriore, and the small State of Pontecorvo, enclosed within the Terra di Lavoro, the States of the Church formed a compact territory, bounded on the N.W. by the Lombardo-Venetian kingdom, on the N.E. by the Adriatic, on the S.E. by the kingdom of Naples, on the S.W. by the Mediterranean, and on the W. by the grand-duchy of Tuscany and the duchy of Modena. On the Adriatic the coast extended 140 m. from the mouth of the Tronto (Truentus) to the southern mouth of the Po, and on the Tyrrhenian Sea 130 m. from 41° 20′ to 42° 22′ N. latitude. The former papal territories are now comprised within the Italian provinces of Bologna, Ferrara, Forlì, Ravenna, Pesaro and Urbino, Ancona, Macerata, Ascoli-Piceno, Perugia, Rome and Benevento. The question of the origin of the territorial jurisdiction of the pope is treated under PAPACY. With the moral and ecclesiastical decay of the papacy in the 9th and 10th centuries much of its territorial authority slipped from its grasp; and by the middle of the 11th century its rule was not recognized beyond Rome and the immediate vicinity. By the Treaty of Sutri (Feb. 1111) Paschal II. was compelled by the Emperor Henry V. to surrender all the possessions and royalties of the church; but this treaty was soon afterwards repudiated, and by the will of Matilda, Countess of Tuscany, the papal see was enabled to lay claim to new territories of great value. By the capitulation of Neuss (1201) the Emperor Otto IV. recognized the papal authority over the whole tract from Radicofani in Tuscany to the pass of Ceperano on the Neapolitan frontier—the exarchate of Ravenna, the Pentapolis, the March of Ancona, the bishopric of Spoleto, Matilda's personal estates, and the countship of Brittenoro; but a good deal of the territory thus described remained for centuries an object of ambition only on the part of the popes. The actual annexation of Ravenna, Ancona, Bologna, Ferrara, etc., dates from the 16th century. The States of the Church were submerged for a time by the groundswell of the French Revolution, but they appeared again in 1814. In 1849 they received a constitution. On the formation of the kingdom of Italy in 1860 they were reduced to the Comarca of Rome, the legation of Velletri, and the three delegations of Viterbo, Cività Vecchia and Frosinone; in 1870 they disappeared from the political map of Europe. From that time, the popes retired within the Vatican as self-constituted prisoners. This situation was changed by the Lateran treaty between the Holy See and the kingdom of Italy (signed Feb. 11, 1929), which recognized Pope Pius XI. as sovereign of a clearly defined territory, indicated by an annexed map, entitled "the city of the Vatican." Therein the Holy See is recognized as having full and exclusive dominion and sovereign jurisdiction. (*See* VATICAN; PIUS XI.)

STATE SUCCESSION. The extent to which a succession State is bound by the obligations of its predecessor constitutes one of the most difficult problems in international law. The clearest statement is probably that contained in the report of the Transvaal Concessions Commission; *see* Parl. Pap. South Africa, 1901 [Cd. 623]. The principles which the commissioners regarded as applicable to the determination of questions relating to various concessions granted by the Transvaal Government in view of the conquest and annexation of the Transvaal by Great Britain are as follows:—(1) "It is clear that a State which has annexed another State is not legally bound by any contract made by a State which has ceased to exist, and that no court of law has jurisdiction to enforce such contracts if the annexing State refuses to recognize them, see *Cook* v. *Sprigg* (1899) A. C. 572. But the modern usage of nations has tended in the direction of the acknowledgment of such contracts. After annexation, it has been said the people change their allegiance, but their relations to each other and their rights of property remain undisturbed, *U.S.* v. *Percheman,* 7 Pet. 51; and property includes rights which lie in contract, *Soulard* v. *U.S.*, 4 Pet. 54." Concessions of a mixed public and private character probably continue to exist after annexation until abrogated by the succession State. There would not appear to be any distinction between cession and annexation. Private rights should be respected, but this is based rather on ethics than law. (2) "Though we doubt whether the duties of an annexing State towards those claiming under concessions or contracts . . . have been defined with such precision in authoritative statement or acted upon with such uniformity in civilized practice, we are convinced that the best modern opinion favours the view that as a general rule the obligations of the annexed State towards private persons should be respected. Manifestly the general rule must be subject to qualification, as that an insolvent State could not by aggression which practically left to a solvent no other course than to annex it, convert its worthless into valuable obligations; again an annexing State would be justified in refusing to recognize obligations incurred by the annexed State for the immediate purposes of the war against itself; and that probably no State would acknowledge private rights the existence of which caused or contributed to cause the war which resulted in annexation." (3) The principle to be adopted was that proclaimed by the Prussians upon the annexation of Hanover "we will protect every one in the possession and enjoyment of his duly acquired rights." (4) "The acceptance of this principle clearly renders it necessary that the annexing Government should in each case examine whether the rights which it is asked to recognize have, in fact, been duly acquired. (5) Thus a concession may properly be cancelled when "(*a*) the grant of the concession was not within the legal powers of the late Government, or (*b*) was in breach of a treaty with the annexing State, or (*c*) when the person seeking to maintain the concession acquired it unlawfully or by fraud, or (*d*) has failed to fulfil its essential conditions without lawful excuse." (6) A concession may be cancelled when its maintenance would be injurious to the public interest.

See A. B. Keith, ***Theory of State Succession*** (1907); Max Huber, ***Die Staatensuccession*** (1898); Westlake, ***Collected Papers;*** Pitt Cobbett, ***Leading Cases on Intern. Law*** Vol. II., 4th ed. (1924).

STATESVILLE, a city of North Carolina, U.S.A., the county seat of Iredell county; 130 m. W. of Raleigh, on Federal highways 21 and 70, and served by the Southern railway. Pop. 7,895 in 1920 (18% negroes); estimated locally at 18,000 in 1928.

The city is in the upper Piedmont section of the State, at an altitude of 960 feet Statesville was laid out in 1790 as the capital of Iredell county (organized 1788), near old Ft Dobbs, which was twice defended against the Indians by Daniel Boone. Kit Carson, the Indian scout, was born near the city During the Civil War Governor Zebulon Vance took refuge in Statesville when Sherman entered Raleigh (April 13, 1865).

STATIC, a term in radio denoting conduction or charging current in an antenna (*q.v.*) resulting from physical contact between the antenna and charged bodies or masses of gas. In America this term is synonymous with atmospherics.

STATICS, the branch of mechanics which discusses the conditions of rest or equilibrium of forces (from Gr. root στα, stand) (*see* MECHANICS)

STATIONARY MACHINERY: *see* FARM (STATIONARY) MACHINERY.

STATIONERY. The word now covers all writing materials and implements, together with the numerous appliances of the desk and of mercantile and commercial offices. The principal articles and operations of the stationery trade are dealt with under such headings as BOOKBINDING; OFFICE APPLIANCES; INK; LITHOGRAPHY; PAPER; PEN and PENCIL.

STATIONS OF THE CROSS, a series of 14 pictures or images representing the closing scenes in the Passion of Christ, viz., (1) the condemnation by Pilate, (2) the reception of the cross, (3) Christ's first fall, (4) the meeting with His mother, (5) Simon of Cyrene carrying the cross, (6) Veronica wiping the face of Jesus, (7) the second fall, (8) the exhortation to the women of Jerusalem, (9) the third fall, (10) the stripping of the clothes, (11) the crucifixion, (12) the death, (13) the descent from the cross, (14) the burial. Sometimes a 15th—the finding of the cross by Helena—is added; on the other hand in the diocese of Vienna, the stations were at the end of the 18th century reduced to eleven. The representations are usually ranged round the church; sometimes they are found in the open air, especially on the ascent to some elevated church or shrine. The normal form of the devotion, which began among the Franciscans, is to visit the stations of the cross wherever represented, and exercise a devout meditation on passing from station to station

See article "Stations of the Cross" in the *Catholic Encyclopaedia.*

STATISTICS. The name *statistics* was first applied to collections of data relating to matters important to the State, such as the numbers of the population, the yield of taxation, the value of trade carried on within the territory of the State or between that territory and other parts of the world, the mortality from particular diseases and from all causes together, etc , and to the study and interpretation of such data. The data were not at first numerical and later not exclusively numerical, but the precision and convenience of data expressed in numbers, as compared with other forms of statement, have led to the more general cultivation of arithmetical data and to the common use of the term "statistics" as if it related exclusively to data expressed in numerical form. At the same time, the numerical data to which the name "statistics" is generally applied are not limited to such as have some connection with the organization or administration of the State, the methods appropriate to the study of statistics being, broadly speaking, the same whether the data under consideration relate to human communities or are concerned with any other branch of knowledge or investigation

Statistical Tables.—The simplest way of arranging numerical records is to set them out in tabular form We may, for example, ascertain the amount of sugar consumed in a given country in each year of a given period A table may be drawn up in which each line contains the figures for the year the date of which is shown at the beginning of the line If each line relates to the year next following that dealt with in the preceding line, the sequence of figures of consumption will enable us to determine whether, and at what rate, the yearly consumption of sugar increased in successive intervals of years The increase of population from year to year observed in most countries is an obvious influence tending to increased use of any popular article of consumption, and it will be advantageous to add, to the figures showing the total consumption of sugar in the country, another series of figures showing the number of persons living in that country in each of the years covered by the table. To the columns containing (1) the dates of the years to which the information relates, and (2) the total amounts of sugar consumed in the respective years, there will thus be added (3) a column showing the numbers of persons concerned in the consumption of these quantities of sugar. The significance of this last column in relation to the preceding may be made clearer by the addition of a fourth column (4) deduced from the two preceding by dividing the quantity of sugar shown in any line of the table by the number of the population shown in the same line, thus obtaining the average amount of sugar consumed per head of the specified population. The form of the table is sufficiently indicated by means of the lines relating to the United Kingdom in ten years, 1903 and 1913, given below:

Consumption of Sugar in the United Kingdom

(1) Year	(2) Total consumption thousand cwt.	(3) Population thousands	(4) Consumption per head, lb.
1903 .	28 847	42 247	76 5
1913	36·734	45·713	90 0

If to this table further columns are added or a new table is drawn up, in which data relating to the consumption of tea in the same country and in the same years is set out, we obtain two sets of facts the comparison of which may prove of interest and importance We can ascertain whether the variations in the consumption of sugar and of tea were related

Graphs.—It is frequently of advantage to set out in diagrammatic form such tabulated results as those referred to, as at least the broader features of the comparison of two or more series of

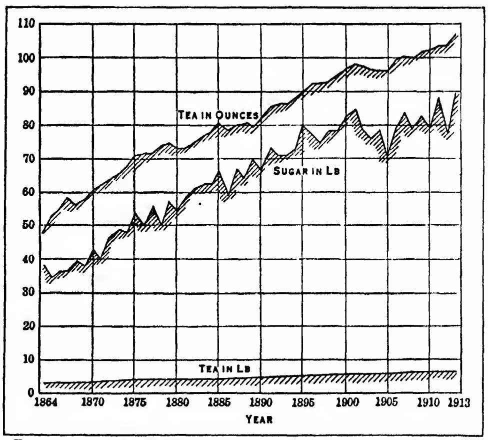

FIG. 1—GRAPH SHOWING CONSUMPTION PER HEAD OF TEA AND SUGAR IN THE UNITED KINGDOM IN EACH YEAR, 1864–1913
Quantities in stock at the end of each year are not taken into account

figures can often be seen more clearly in this form. Such simple graphical comparisons are familiar through their use in meteorological reports where readings are shown by the upward and downward movements of a line crossing from left to right a series of vertical lines marking the hours of the day or the days of the week. The particulars of the consumption, per head of the population of the United Kingdom, of sugar and of tea in each of the 50 years from 1864 to 1913, are thus shown in Fig. (1). A necessary precaution in planning such graphical comparisons is also illustrated in the same diagram. The figures which are plotted relating to sugar show the average consumption year by year in lb. per head. The consumption of tea in lb. per head yields the

line at the foot of the diagram, the variations of which are so slight as to suggest no similarity with those of the line showing sugar consumed. If, however, the consumption of tea per head is expressed in ounces, it becomes clear that, though in individual years the variations shown are by no means similar for sugar and for tea, over the whole period the increase was in approximately the same proportion for these two commodities[1]. The fluctuations were more considerable in the case of sugar, and the diagram suggests that, up to 1901, the quantities of sugar increased somewhat more rapidly than, and thereafter failed to maintain as great an increase as, those of tea.

Even though graphs fall short, in the matter of precision of statement, of the numerical tables, they have the great advantage of enabling a large mass of figures to be grasped as a whole much more readily than is possible when those figures are presented in one or more tables.

Averages and Dispersion.—A second illustration of statistical series is seen in the following summary of the heights of a number of men:—

Height in inches.	61	62	63	64	65	66	67
Number recorded	2	10	11	38	57	73	106
Height in inches.	68	69	70	71	72	73	74
Number recorded	126	109	87	75	23	9	4

The table may be interpreted as meaning that 126 were found between 5 ft. 7½ in. and 5 ft. 8½ in. and similarly for other heights. In tables such as this some method of dealing with cases falling exactly on the dividing line between two adjacent groups must be laid down, and a common method is to assign half the number found on the dividing line to each of the classes of which it forms the limit. This procedure may, of course, result in numbers in some of the groups which are not integers. The true average height of the 730 men covered by the table can be ascertained only by reference to a more detailed statement showing the height of each man exactly, instead of in a number of groups. It will be observed that 297 were not taller than 5 ft. 7½ in., while 307 were 5 ft. 8½ in. or more, the distribution being not quite symmetrical on both sides of the numerically largest group. The approximate average height was about $\frac{1}{20}$in. less than 5 ft. 8 in.

A table of this kind tells us, however, something more than the average height of the individuals represented. We note that 191 were not more than 5 ft. 6½ in. in height and 198 were not less than 5 ft. 9½ in. in height. By calculation from the figures shown, assuming that the individual heights were distributed with approximate regularity along the intervals from inch to inch, the points representing 5 ft. 6·3 in. and 5 ft. 9·7 in. would divide the series of heights so that one-quarter of the whole number fell below the former, and one-quarter of the whole number above the latter. A similar calculation gives, as the point dividing the series into two equally numerous groups, 5 ft. 8·04 in. This last point is called the *median* of the series, and the two others are the *lower* and *upper quartiles,* the three points serving to divide the whole number examined into four groups of equal numbers of cases. The distance between the upper and lower quartiles, in the case in question 3·4 in., gives the range within which the middle half of the instances recorded lay. This distance expresses much more definitely the degree of concentration of the individuals in the neighbourhood of the median height than, for example, the whole range (14 in.) within which all the measurements lie. If a more exact description of the nature of the distribution than is afforded by the specification of the median and quartiles, but of the same general character, is desired, the group may be divided into a number of parts, *e.g.,* into ten equally numerous parts, the points of division being then known as *deciles.*

In many varieties of statistical problems it is found that the observations are distributed in a manner similar to that shown in the above illustration, and the question arises whether the form of the distribution is of a recognizably definite character, the determination of which can be of use in the interpretation of the results obtained. It is found that, in numerous cases, the manner in which the individual observations are distributed is in close accordance with that of events dependent on pure chance. Such a case is presented by the following. A number of balls, indistinguishable in size, weight or form, are placed in a bag, half of the balls being white and half black. If one ball be drawn from the bag, its colour, whether white or black, may be noted. The ball being replaced and the bag shaken, another drawing will give a result wholly independent of the first. The repetition of such drawings will furnish a record of runs of white and of black balls, some short, some long. The numbers of cases (a) of a change of colour in consecutive drawings (b) of sequences of the same colour of two, three, four, etc., in number, being noted, the material for a table is furnished, and this table would have a general similarity with that of the men's heights used above for illustration. It is possible to determine theoretically the relative frequency with which the various sequences would recur in a series of trials indefinitely extended.

If, in a large number of drawings, sequences of x_r white (or of x_r black) balls are recorded on Y_r occasions, the total number n of drawings will be expressed by $n=x_1Y_1+x_2Y_2+x_3Y_3+ \dots +x_rY_r+ \dots$ The relative frequencies of the different series are y_1, y_2, etc., where $n \cdot y_1 = Y_1$, $n \cdot y_2 = Y_2$, etc., and, when n is indefinitely increased, the relation between the x's and the y's is expressed by the formula $y=a \cdot e^{-mx^2}$, which represents a curve of the shape shown below in fig. (2), known as the probability curve.

It is not proposed to enter into discussion of the character of the probability curve, or the interpretation of the variations. It will be sufficient here to point out that the equation given relates to a curve symmetrical in form to right and left of the position represented by $x=0$. The part to the right may be supposed to show the record of white sequences, and that to the left the exactly similar record of black sequences, *i.e.,* of sequences in which white balls failed to appear.

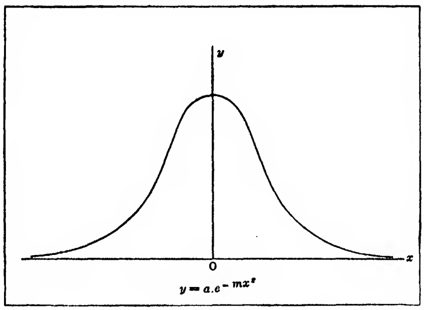

FIG. 2

In any actual series of observations (*e.g.,* of the colours of balls drawn from, and returned to, a bag) the observed numbers expressing the frequency of different events will be found to differ more or less from those expressed by the curve, of the form given by the above equation, which is appropriate to the circumstances of the experiment. Prolonged trials would give results approximating to those derived from theoretical calculations and expressed in the shape of the probability curve. Thus, in the case of the heights of 730 men, it is probable that records covering larger numbers of men, of the same race and social condition and within the same limits of age as those from which the 730 were selected, would give a distribution of heights more closely corresponding to that shown by a typical probability curve than the numbers cited. If, for example, for every one actually covered by our table, 10 or 20 or 50 or 100 had been measured, closer correspondence with a suitably selected theoretical series would have been probable.

In considering the meaning of changes in the observed frequency of events, it is generally of considerable importance to ascertain what is the extent of variation that is as likely to happen as not, since the significance of actual variations can only be

[1]*Cf.* Jubilee Vol. of the Royal Statistical Society, p. 257, where the late Professor Marshall used this illustration. The figures are based on imports less exports of sugar, excluding sugared goods.

judged in relation to those which may have no significance at all in reference to the problem under consideration.

Skew Distributions.—The normal probability curve, referred to above, is not the only form resulting from the theoretic consideration of chance events, and presenting close correspondence with statistical records of various kinds The study of these forms, and of their theoretical bases, has been particularly active since the last decade of the 19th century. It will suffice here to mention that particular statistical problems are found to yield distributions of observations, not only symmetrical on either side of their mean, as with the normal probability curve, but also grouped more closely on one side of the mean than on the other The illustration from men's heights showed some small tendency to a skew shape, though it appears possible that the apparent deformation would, on extending the field of observation, be found to disappear and be shown to result from the fact that, in so small a number of cases as 730, the even representation of men of all heights in the population from which these cases were drawn had not been exactly secured The following records of weights of men of 25 and less than 30 years of age and within half an inch of 5 ft 6 in in height, shows a more marked skewness.

Weight in lb	105	120	135	150	165	180	195	210
Number of cases	17	722	2,175	1,346	485	155	33	3

In this case the average (or arithmetic mean) of the weights of the 4,936 men is, on the assumption of continuous distribution, approximately 141·6 lb. The median is at about 1 lb. less, viz, 140·5 lb In the previous illustration of heights, the median was greater than the mean, so that the skewness shown is of opposite direction in the two cases

This illustration serves also to show a third characteristic of statistical distributions of this kind Nearly four of every nine cases are included in that one of the eight groups of which 135 lb. is the central point, this group being notably more numerous than any other The weight 135 lb may be called, so far as the figures furnish a ready indication, the most generally occurring weight or the "modal" weight The point in the distribution thus determined is called the "mode" A table like the above does not, however, give a very close measure of the central point of the group (covering a range of 15 lb) which would prove largest if we compared various groups such as 127½ to 142½ lb (the group shown) 127 to 142 lb, 128 to 143 lb, and so on If the curve be found which represents the distribution in question, its highest point is the point the weight corresponding to which is the "mode" of the distribution, the most prevalent weight in the distribution under examination. Various problems in probability lead to curves of the distribution of chances which show the skewness that marks groups of statistical observations

Groups That Are Not Homogeneous.—A case that may, however, be mentioned is that in which the measurements obtained relate, not to a homogeneous group, but to a mixture of two or more groups The manner in which such a mixture might affect the characteristics of a distribution may be illustrated from the figures given below for the heights of a particular group of men Suppose two such groups were found differing in the heights of the individuals composing them, but in such a way that the numbers in one of them whose heights were between any two specified limits were exactly twice those for limits an inch higher in the other group We might have, for example —

Height in inches	60–61	61–62	62–63	63–64	64–65	65–66	66–67	67–68	68–69	69–70	70–71	71–72	72–73	73–74	74–75
Numbers in Group I	4	20	22	76	114	146	212	252	218	174	150	46	18	8	
Numbers in Group II		2	10	11	38	57	73	106	126	109	87	75	23	9	4
Numbers in the two groups	4	22	32	87	152	203	285	358	344	283	237	121	41	17	4

The numbers in the last row represent a compound of two groups as numerous as the original group, the individuals of each of which were half an inch shorter than those of the original group, and another group, equal in number to the original group, the individuals of which were half an inch taller than those of the original group. If the distribution of the original group were such as could be precisely represented by an appropriate theoretical formula, the compound group would not be, in general, represented by the same formula In some instances, it has been found possible to show that an observed group was so distributed as to be consistent with the assumption that it was made up of two groups of different characteristics, the members of which were included within one and the same series of observations Such an analysis can clearly be of considerable importance with reference to the deductions to be drawn from the examination of the observed data.

Three Variable Elements.—In what precedes, the statistical material considered has consisted of series of pairs of quantities, the values of the two quantities in each pair being related; for example, where one of the quantities is the height of a man, the other the relative frequency with which men of that height were observed We pass now to the consideration of series of three quantities, for example, where two of the quantities express the measures of different phenomena (which may be connected in some way, or may be independent) and the third expresses the relative frequency with which any combination of the other two occurs. Such a series is represented in the table given below, which shows the proportions in which, over a period of years, in a particular country, marriages in which both bride and bridegroom had been married previously were distributed according to the ages of the brides and of the bridegrooms The particulars might advantageously be set out in fuller detail, but the condensed table will serve quite well to illustrate the nature of the problems connected with the analysis of data of this kind

Ages of wives at date of marriage	Ages of husbands at date of marriage						Total wives
	Under 25	25–34	35–44	45–54	55–64	65 and over	
Under 25	10	75	46	13	3		147
25–34	20	175	167	65	17	3	447
35–44	5	54	104	79	29	7	278
45–54		5	18	36	33	9	101
55–64			1	5	13	5	24
65 and over .					1	2	3
Total husbands	35	309	336	198	96	26	1,000

The table is to be read as follows. Of each thousand women married for the second (or later) time to men who had been married before, 447 were between 25 and 35 years old, and of these 20 married men under 25 years of age, 175 married men between 25 and 35, 167 married men between 35 and 45 and 17 men between 45 and 55 The other rows of figures will be read similarly, and the columns are to be read in corresponding manner, with the words "husband" and "wife" interchanged

The columns, and also the rows, representing the age distributions of particular sections of the wives and of the husbands, are examples of skew distribution of numbers It is clear, from the clustering of numbers in the neighbourhood of a band crossing the table from its upper left side towards its lower right side, that there is some association between the ages of the wives and the husbands, which are more often relatively high together, or relatively low together, than in other relations The average age of the husbands is near 41 years and that of the wives somewhat in excess of 34 years

Correlation.—If the average ages of the husbands shown in each row of the table be computed, and also those of the wives shown in each column, the two series of figures thus obtained show

the variation of the average ages of corresponding groups of husbands and wives. They furnish the measures of what are known as the regression of the ages of husbands on those of wives, and the regression of the ages of wives on those of husbands. The two regressions would be complementary if the distribution represented complete linear correlation of husbands' ages and wives' ages. When this complete correlation is not shown, a measure of the degree in which the distribution diverges from that corresponding to complete correlation is afforded by the so-called coefficient of correlation. Between two series of quantities

$$x_1,\ x_2,\ x_3\ \ldots\ldots$$

and

$$y_1,\ y_2,\ y_3\ \ldots\ldots$$

if the sums of the squares of each series, $S(x^2)$ and $S(y^2)$ be calculated, and the sum of the pairs of products x_1y_1, x_2y_2, x_3y_3 . . . , *i.e.*, $S(x{\cdot}y)$ be also calculated, the fraction $S(x{\cdot}y)/\sqrt{[S(x^2){\cdot}S(y^2)]}$ gives the coefficient of correlation.

In the case represented by the final row and the final column of the last table, the calculation gives a fraction exceeding ·9. The highest possible value for the coefficient is 1. The coefficient is a measure of the divergence between the two lines of regression in cases like that illustrated, those two lines coalescing when the correlation is complete. If the series compared are such that decreases in the one correspond to increases in the other, the calculated coefficient is negative. The range of values for the coefficient lies between 0 and 1 for positive correlations and between 0 and —1 for negative correlations. Small values of the coefficient mean that the connection between the series is slight, and, in view of the extent to which, in actual observations, the records obtained are affected by disturbances having no relation to the matter under examination, no great significance can generally be attached to the occurrence of correlation coefficients of small magnitude.

The class of problem of which the figures given in the last table furnish an illustration is one of great importance in statistical work. Thus the variation of the height and weight of men with their age, the questions relating to the transmission of characteristics from parents to children, the association of different diseases or defects and the results of combinations of treatment of diseases or defects, the interpretation of the results of variation in different features of the weather, for example rainfall and temperature, on crop yields and many other problems give rise to such distributions, while the limitation of the illustration to the case of three kinds of variation should not be taken to imply that larger numbers of elements may not be considered.

The practical application of the procedure of calculating coefficients of correlation is not confined to cases such as that in connection with which the nature of correlation was illustrated. It may also be applied to determine, in cases such as that of the consumption of sugar and of tea, illustrated earlier, the closeness with which the variations in the two series of figures coincide. In some cases it is of importance to compare, not two series the trends of which are, on the whole, similar, but two series of which the trends are different, though the variations from the general trend may prove to be similar in the two cases. Whether for diagrammatic representation, or for preliminary arrangement of material for testing by the calculation of coefficients of correlation, it is desirable to isolate the important features as far as possible. The relation between economic prosperity and the marriage rate is a problem that has attracted much attention, and in using as a measure of economic prosperity the value of the exports year by year, or of imports and exports together, the connection which appears in some periods may be obscured in later periods by other conditions which cause one or other, or both, of the curves compared to diverge from the trend previously shown. To a considerable extent the effect of these disturbing elements in obscuring the significant relation may be evaded by using for comparison, not the absolute measures, *e.g.*, of the value of trade and of the marriage rate, but the proportion in which the figures for a given year are in excess or defect in comparison with those of the average of a series of several years of which the year under consideration is the middle year, or the final year.

It may be noted that when two series of quantities, showing the variations in time of phenomena under examination, are tested for closeness of fit by the calculation of correlation coefficients, it is possible to test whether one of the two series differs from the other mainly in respect of the time at which variations are greatest or smallest. In comparing two series such as

$$x_1\ x_2\ x_3\ x_4\ \ldots\ldots$$
$$y_1\ y_2\ y_3\ y_4\ldots\ldots$$

the sum of products used in calculating the correlation coefficient was conceived of as

$$x_1\ y_1 + x_2\ y_2 + x_3\ y_3 + \ldots\ldots$$

It may be found that such product-sums as

$$x_1\ y_2 + x_2\ y_3 + x_3\ y_4 + \ldots\ldots$$

or

$$x_2y_1 + x_3y_2 + x_4y_3 + \ldots\ldots$$

show significantly larger resulting coefficients than the product-sum first named. If so, it may be taken as meaning that of the two phenomena the variations of which are compared, those variations are not contemporaneous, but the members of one series follow, or precede, those of the other by a roughly constant interval. The repetition of the calculations for several different intervals may furnish a measure of the lag of one of the two phenomena on the other.

It has been stated that the lowest value of the correlation coefficient is zero. It may be added that when, in practice, a calculation of such a coefficient gives a result practically equal to zero, it is not to be concluded that there is no correlation between the quantities. The form given for the correlation coefficient was based on the assumption that the lines of regression were sufficiently nearly straight lines to render it unnecessary to call attention to their divergence from that form. In some cases in which a high correlation with non-linear regression exists, the coefficient calculated by the formula given will be small. On the other hand, there are cases in which large correlation coefficients result from the formula of calculation, though the phenomena compared are, in fact, not related to each other. The principal cause of such apparently strange results is found in the fact that actual series of observations may be but small samples of the universe of phenomena of which they are taken as representative, and in small samples the securing of really representative results is not easily achieved. We turn, therefore, to the consideration of some questions relative to sampling.

Sampling.—Two principal reasons lead to the use of statistics of samples in place of complete statistics of an exhaustive character covering the whole of the so-called universe of instances. One is that only portions of that universe may be accessible as sources of data, the other that the labour and expense involved in handling very large masses of statistics render it expedient to seek representative selections of moderate extent as the basis of the data to be submitted to detailed examination. In the latter case, it is to be supposed that the selection of instances is at the discretion of the investigator, and the practical question involved is the devising of a means that will ensure that the instances selected should give, as far as is possible, a picture *in petto* of the whole field of enquiry.

The most common method is to choose the instances in a manner that shall ensure that there is no concentration on those possessing any particular characteristic in preference to those lacking that characteristic. All cases are to be given an equal chance of selection; the sample is to be a *random* selection. It is only necessary to illustrate the kind of procedure that will secure that result. Suppose we have to select 200 cases from a total of (say) 20,000. We may, if the 20,000 are arranged in any kind of sequence, take the first, pass over 99 and take the case then next following, again pass over 99 and take the case then next following, and so on. Another method would be to place in a bag cards bearing the series of numbers from 1 to 20,000 and to draw from the bag 200 cards in succession, shaking the bag between each pair of drawings. The numbers of the cards drawn would show what choice of cases from the complete series should be made, and any effect produced by the arrangement of the cases in a particular order, which might influence the result of the method of selection first named, would tend to be avoided by the second procedure.

Random sampling has, as its object, as already stated, the securing of a comparatively small group possessing the same general characteristics, *i.e*, showing the same proportions in which each special feature is present or absent, as the complete series of cases. This may, in some conditions, be secured more effectively by deliberate selection of instances in which a number of characteristics are distributed in a manner similar to that in which the same characteristics are distributed in the mass from which the sample is taken This involves, of course, that, in respect of the characteristics used as guides, available records exist covering the mass.

Another mode of testing a sample in respect of its representative character is to divide it into two or more parts at random, and compare the characteristics of the separate parts. Agreement between the parts is commonly taken as an indication that the sample is representative in character, though such agreement, or its absence, is not a final test. To illustrate, suppose the special case of random samples of men of specified age from a defined race and locality. Suppose a sample of 1,000 such men taken, and their characteristics examined for example, their average height, median height, the dispersion of these heights and other features of the distribution of heights may be determined. The process may be repeated for a second, third, etc., sample of 1,000 until we have (say) 1,000 sets of results derived from 1,000 samples each consisting of 1,000 units. Taking one of the characteristics, say the average height, we may examine 1,000 results from the separate samples. It will almost certainly happen that these differ from one another but slightly as compared with the differences between the heights of the individuals in any one sample. But these averages would themselves generally possess a degree of variation, and their grouping according to their order of magnitude would furnish a frequency distribution having its own mean, median, dispersion, etc. This latter distribution would, in fact, indicate the degree of variability of the results obtained by sampling.

The study of the mathematical theory relating to the problems thus illustrated furnishes estimates of the answers to such questions as: what is the probability that the divergence of the mean value of a specified feature of the sample from the (unknown) mean value of the same feature of the universe from which the sample is drawn shall not be greater than a specified amount? The answers may be a guide to a decision on the questions of whether procedure by sample is satisfactory, and what size of sample may be desirable to justify the use of the sampling method

When procedure by sample is adopted because only data derived from samples are procurable, the investigation of the entire mass of cases being excluded, the use of methods aimed at securing that the samples are *random* or are *representative* is, generally if not universally, not a matter for consideration. It is, therefore, of the greatest importance to examine the conditions affecting the selection of the sample. It may be found that some bias in the selection is unavoidable, while the extent to which that bias affects the results may not be capable of estimation. To apply to the results of biassed sampling the tests and limitations determinable by theory for the case of random sampling may lead to error.

The relative stability of the relations between different groups of statistics relating to human communities and their organization was a feature that attracted attention at a very early stage of statistical enquiry. Changes in habits of masses of men are generally of slow development The consequence is that any well ascertained sequence of phenomena in economics may be expected to be repeated, that is, the repetition of certain conditions may be expected to be followed by consequences of a definite character The underlying assumption is the permanence of the essential determining features of the organism with whose manifestations we are concerned The introduction of new conditions, not all of which may be obvious or ascertainable, may destroy that stability of relations on the faith of which future changes might be expected when observed conditions show particular mutual relations. Not only new conditions, but also the deviations from uniformity recognizable in the comparison of different samples of one and the same universe of phenomena, must be kept in mind in forming any judgment of the probable future based on observations of the course of events in the recent past

Sources of Statistical Data.—In the work of administration, the governments of most civilized countries are able to make exhaustive enumerations of various classes of events occurring within their territory. A few examples are:—the number of births in successive weeks, months or years, the deaths in the same periods, the causes of deaths and the sexes and ages of the persons dying, the amount of property or income serving as the basis of assessment to taxation of individual citizens, the value and quantity of each of various kinds of merchandise imported from or exported to other countries during any determined interval of time, the numbers of various kinds of animals existing in the country at selected dates, the length of the roads maintained at the public expense and of the railway tracks existing from time to time, the numbers of various kinds of vehicles for the use of which licences are required, the quantities of certain dutiable articles of food and drink on which duties are paid in successive months or years.

From time to time, generally at intervals of ten years, the total number of persons of each sex, the age of each being also recorded, is ascertained for each administrative subdivision of the country, and either simultaneously or on other, and possibly less frequent, occasions the number of persons engaged in each principal class of occupation is also generally ascertained.

Organizations of a private character, including corporate bodies, obtain, like the public administrative bodies, much information for their own guidance, some of which is made public In some cases there results an exhaustive enumeration of events of certain kinds occurring within the country, in other cases a series of more or less representative illustrations of what has happened is furnished Thus the total weight of goods carried by railway may be available, while the quantities of gas, water or electricity supplied may only be made public by some of the undertakings supplying them, and the extent to which the ascertained aggregates fall short of the actual aggregates supplied may be variable in a degree that cannot be determined and may be of importance.

In addition to the data arising out of the general administration of a country, and those published by business organizations, statistical data may be obtained as the outcome of special enquiries by either of these classes of bodies or by private bodies or persons. The latter class of data generally presents the characteristic just referred to as affecting some of the data obtained by business organizations, namely, that an exhaustive enumeration covering the whole country is not secured. What is obtained is a record relating to a part, more or less typical of the whole so far as the matter under examination is concerned. The principles to which attention was directed in the paragraphs relating to sampling apply to the statistics thus secured. (A W. F)

STATIUS, PUBLIUS PAPINIUS (*c.* A.D. 45–96), Latin poet, was born at Naples His father was also a poet, and Statius seems to have been trained as one from the start. Of events in the life of Statius we know little. From his boyhood he was victorious in poetic contests—many times at his native city Naples, thrice at Alba, where he received the golden crown from the hand of the emperor Domitian. But at the great Capitoline competition (probably on its third celebration in A.D. 94) Statius failed to win the coveted chaplet of oak leaves. Perhaps the emperor's favour had failed him; in any case, he withdrew to Naples (*Silv* iii. 5)

The rôle of court poet seems to have suited Statius His flattery is as far removed from the gentle propitiatory tone of Quintilian as it is from the coarse and crawling humiliation of Martial It is in the large extravagant style of a nature in itself healthy and generous, which has accepted the theme and left scruples

behind. In one of his prefatory epistles Statius declares that he never allowed any work of his to go forth without invoking the godhead of the divine emperor. Statius had taken the full measure of Domitian's gross taste, and, presenting him with the rodomontade which he loved, puts conscience and sincerity out of view, lest some uneasy twinge should mar his master's enjoyment.

As a poet, Statius unquestionably shines in many respects when compared with most other post-Augustans. He was born with exceptional talent, and his poetic expression is, with all its faults, richer on the whole and less forced, more buoyant and more felicitous, than is to be found generally in the Silver Age of Latin poetry. Statius is at his best in his occasional verses, the *Silvae*, which have a character of their own, and in their best parts a charm of their own. The subjects of the *Silvae* are very various. Five poems are devoted to flattery of the emperor and his favourites; but of these enough has already been said. Six are lamentations for deaths, or consolations to survivors. Another group of the *Silvae* give picturesque descriptions of the villas and gardens of the poet's friends. In the "Kalendae decembres" we have a striking description of the gifts and amusements provided by the emperor for the Roman population on the occasion of the Saturnalia. In his attempt at an epithalamium (*Silv.* i. 2) Statius is forced and unhappy. But his birthday ode in Lucan's honour (*Silv.* ii. 7) has, along with the accustomed exaggeration, many powerful lines, and shows high appreciation of preceding Latin poets. Some phrases, such as "the untaught muse of high-souled Ennius" and "the lofty passion of sage Lucretius," are familiar words with all scholars.

The epic poems of Statius are less interesting because cast in a commoner mould, but they deserve study in many respects. They are the product of long elaboration. The *Thebais*, which the poet says took 12 years to compose, is in 12 books, and has for its theme the old "tale of Thebes"—the deadly strife of the Theban brothers. There is also preserved a fragment of an *Achilleis*, consisting of one book and part of another. In the weary length of these epics there are many flowers of pathos and many little finished gem-pictures, but the trammels of tradition, the fashionable taste and the narrow bars of education check continually the poet's flight.

The *editio princeps* of the epics is dated 1470, of the *Silvae* 1472. Notable editions since have been those of Bernartius (Antwerp, 1595), Gronovius (1653) and Barth (1664). Recent texts are the Teubner (the *Achilleis* and *Thebais* by Kohlmann, the *Silvae* by Baehrens) and that contained in the new edition of the *Corpus poetarum latinorum;* and of the *Silvae* only, texts by Klotz (1899), and Vollmer (1898), the last with an explanatory commentary. Among editions of portions of Statius's works, that of the *Silvae* by Markland (1728) deserves special attention. A translation of the *Silvae* with introduction and notes was published by D. A. Slater in 1908 (Oxford Library of Translations). A critical edition of the *Thebais* and *Achilleis* was begun by O. Müller (*Thebaid* i.–vi., Leipzig, 1870) but not completed.

For the poet's life *see* Lehanneus, *De P. P. Statii Vita et Operibus* (La Rochelle, 1878); *Riv. Fil.* 35 (1907) 3. *See* also B. A. Wise, *Influence of Statius upon Chaucer* (Baltimore, 1911); W. A. Menite, *Notes on the Silvae* (Univ. of California, 1918). (J. S. R.; X.)

STATUTE, in English law, is a law made by the "sovereign power" in the State. (*See* ACT OF PARLIAMENT.) It forms a part of the *lex scripta,* which by English legal authorities is used solely for statutory law, a sense much narrower than it bore in Roman law. To make a statute the concurrence of the Crown and the three estates of the realm is necessary. Thus a so-called statute of 5 Ric. II. c. 5, directed against the Lollards, was afterwards repudiated by the Commons as passed without their assent. The validity of a statute was indeed at times claimed for ordinances such as that just mentioned, not framed in accordance with constitutional rule, and was actually given to royal proclamations by 31 Hen. VIII. c. 8 (1539). But this Act was repealed by 1 Edw. VI. c. 12, and since that time nothing but a statute has possessed the force of a statute, except perhaps certain subordinate legislation ("Statutory Rules and Orders"), the making of which has been delegated by parliament to departments and other authorities (*see* also PROVISIONAL ORDER), and except Church Assembly Measures passed under the Church of England Assembly (Powers) Act of 1919 and presented for the royal assent after a favourable resolution of both houses of parliament.

The list of English statutes as at present existing begins with the Statute of Merton, 1235. Many of the earlier statutes are known by the names of the places at which they were passed, *e.g.*, the Statutes of Merton, Marlbridge, Gloucester, Westminster, or by their initial words, e.g., *Quia Emptores, Circumspecte Agatis.* The earliest existing statute roll is 6 Edw. I. (the Statute of Gloucester). After 4 Hen. VII. the statute roll ceased to be made up, and enrolments in chancery (first made in 1485) take its place.

All statutes were originally public, irrespective of their subject-matter. The division into public and private dates from the reign of Richard III. At present statutes are of four kinds, public general Acts, public local and personal Acts, private Acts printed by the king's printers and private Acts not so printed. The division into public general and public local and personal rests upon a resolution of both houses of parliament in 1798. In 1815 a resolution was passed in accordance with which private Acts are printed, with the exception of name, estate, naturalization and divorce Acts. The last two are now practically superseded by changes in the law of divorce and nationality. Since 1815 it has been usual to refer to public general Acts by Arabic numerals, *e.g.,* 1 Edw. VII. c. 21, public local and personal Acts by small Roman numerals, *e.g.,* 1 Edw. VII. c. xxi. Each Act is strictly but a chapter of the legislation of the session, which is regarded as composing a single Act divided into chapters for convenience, the chapters themselves being also called Acts. The citation of previous Acts is provided for by the Interpretation Act 1889 (s. 35). Every Act now contains a short title by which it may be cited, *e.g.,* the Housing Act 1925. The Short Titles Act 1896 creates short titles for numerous single Acts and groups of Acts, and it is now usual to cite Acts and groups by their short and collective titles rather than by the year of the reign.

A public Act binds all subjects of the realm, and need not be pleaded (except where the law from motives of policy specially provides for pleading certain Acts, as in the defences of not guilty by statute, the Statute of Frauds and the Statute of Limitations). A private Act must generally be pleaded, and does not as a rule bind strangers to its provisions. Formerly an Act took effect from the first day of the session in which it was passed. The hardship caused by this technical rule was obviated by statute in 1793, since when an Act takes effect from the day on which it receives the royal assent, where no other date is named. This has been held to mean the beginning of the day, so as to govern all matters occurring on that day. An Act cannot in the strict theory of English law become obsolete by disuse. Nothing short of repeal can limit its operation. The law has, however, been interpreted in many cases with somewhat less rigour. In the case of a prosecution for blasphemy in 1883 (*R.* v. *Ramsay*) Lord Coleridge said, "though the principles of law remain unchanged, yet (and it is one of the advantages of the common law) their application is to be changed with the changing circumstances of the times." This would be applicable as much to the interpretation of statutes as to other parts of the common law.

Besides the fourfold division above mentioned, statutes are often classed according to their subject-matter, as perpetual and temporary, penal and beneficial, imperative and directory, enabling and disabling. Temporary Acts expire at a date fixed in the Act itself. Thus the Army Act is passed annually and continues for a year, and the London Traffic Act 1924 was to expire at the end of 1928. By such provision experimental legislation is rendered possible where the success of a new departure in legislation is doubtful. An annual Expiring Laws Continuance Act is passed for the purpose of continuing (generally for a year) various temporary Acts; the list is periodically revised and those of proved value are then made permanent. By legislation of 1808 a continuing Act is to take effect from the date of the expiration of a temporary Act, where a bill for continuing the temporary Act is in parliament, even though it be not actually passed before the date of the expiration. Penal Acts are those which impose a new disability; beneficial, those which confer a new favour. An imperative statute (often negative or prohibitory in its terms) makes a certain Act or omission absolutely necessary, and subjects a contravention of its provisions to a penalty. A directory statute (gen-

erally affirmative in its terms) recommends a certain Act or omission, but imposes no penalty on non-observance of its provisions. To determine whether an Act is imperative or directory the Act itself must be looked at, and many nice questions have arisen on the application of the rule of law to a particular case. Enabling statutes are those which enlarge the common law, while disabling statutes restrict it This division is to some extent coincident with that into beneficial and penal Declaratory statutes, or those simply affirming the common law, at one period not uncommon, are at the present time practically unknown; the Treason Act is an example.

Interpretation of Statutes.—The construction or interpretation of statutes depends partly on the common law, partly on statute The main rules of the common law, as gathered from the best authorities, are these. (1) Statutes are to be construed, not according to their mere letter, but according to the intent and object with which they were made. (2) The relation of the statute to the common law is to be considered In the words of the resolution of the court of exchequer in *Heydon's case,* 3 Coke's Rep. 7, the points for consideration are: "(*a*) What was the common law before the making of the Act? (*b*) What was the mischief and defect against which the common law did not provide? (*c*) What remedy the parliament hath resolved and appointed to cure the disease of the Commonwealth? (*d*) The true reason of the remedy." (3) Beneficial or remedial statutes are to be liberally, penal more strictly, construed (4) Other statutes *in pari materia* are to be taken into consideration. (5) A statute which treats of persons of inferior rank cannot by general words be extended to those of superior rank. (6) A statute does not bind the Crown, unless it be named therein. (7) Where the provision of a statute is general, everything necessary to make such provision effectual is implied. (8) A later statute repeals an earlier, as far as the two are repugnant, but if they may stand together repeal will not be presumed. (9) There is a presumption against creation of new or ousting of existing jurisdictions, against impairing obligations, against retrospective effect, against violation of international law, against monopolies, and in general against what is inconvenient or unreasonable (10) If a statute inflicts a penalty, the penalty implies a prohibition of the Act or omission to which the penalty is imposed. Whether the remedy given by statute is the only one depends on the words of the particular Act. In some cases an action or an indictment will lie; in others the statutory remedy, generally summary, takes the place of the common law remedy In some instances the courts have construed the imposition of a penalty as operating not to invalidate a contract but to create a tax upon non-compliance with the terms of the statute. The Interpretation Act 1889 provides an authentic interpretation for numerous words and phrases of frequent occurrence in statutes

The earlier Acts are generally simple in character and language, and comparatively few in number. At present the number passed every session is substantial; for the session of 1925 there were 91 general Acts (occupying over 1,800 pages in the official volumes) and 132 local and personal Acts Without going as far as to concede with an eminent legal authority that of such legislation three-fourths is unnecessary and the other fourth mischievous, it may be admitted that the immense library of the statutes would be but a trackless desert without trustworthy guides. Revision of the statutes was evidently regarded by the legislature as desirable as early as 1563 (*see* the preamble to 5 Eliz c 4). It was demanded by a petition of the Commons in 1610 Both Coke and Bacon were employed for some time on a commission for revision. In 1861 was passed the first of a long series of Statute Law Revision Acts The most important action, however, was the nomination of a Statute Law Committee by Lord Chancellor Cairns in 1868, a body of experts in drafting and public administration, which continues to supervise the official publication of revised statutes and indexes to statutes and to statutory rules *A Chronological Table and Index of the Statutes* which are still law is annually published under the Committee's direction; the Table shows how far any enactment has been repealed or amended. The first edition of *Revised Statutes,* begun in 1870, substituted 18 volumes for 118; a second edition, begun in 1886, contains the Acts from 1235 to 1900 in 20 volumes, extended further by the Statute Law Revision Act of 1927.

The chief editions of the British statutes are the *Statutes of the Realm* printed by the king's printers, Ruffhead's and the fine folio edition issued from 1810 to 1824 in pursuance of an address from the House of Commons to George III. The safest authority is the *Revised Statutes.* Chitty's selection of *Statutes of Practical Utility* is useful Earlier works on statute law include the readings and commentaries on statutes by great lawyers, such as the second volume of Coke's *Institutes,* Bacon's *Reading on the Statute of Uses,* Barrington's *Observations on the more ancient Statutes from Magna Carta to the 21 Jac I. c. 27* (5th ed, 1796), and the Introduction to Blackstone's *Commentaries.* Among the later works are the treatises of Dwarris (2nd ed., 1848) and Maxwell (6th ed., 1920) and Craies (founded on Hardcastle) (3rd ed, 1923). On the interpretation of statutes, *see* Sir C. P. Ilbert, *Legislative Methods and Forms* (1901) and *Mechanics of Law-Making* (1914); Sir H. Thring, *Practical Legislation* (1902) An official *Index to Statutory Definitions* (1923) is valuable for draftsmen For bibliography of English Statutes *see* P. H Winfield, *Chief Sources of English History* (1925). For Revised Statutes see *Law Quarterly Review* (1929, p. 168). Statutory rules and orders are officially published by H.M. Stationery Office both singly and in annual volumes

Scotland.—The statutes of the Scottish parliament before the union differed from the English statutes in two important respects. they were passed by the estates of the kingdom sitting together and not in separate houses, and from 1367 to 1690 they were discussed only after preliminary consideration by the lords of the articles, a legislative committee An Act of the Scottish parliament may in certain cases cease to be binding by desuetude

Acts of the imperial parliament which have been passed since the union extend in general to Scotland, unless that country be excluded from their operation by express terms or necessary implication. Scottish Acts are cited thus, 1678, c 10. An edition was issued by order of the Treasury, 1844–75 *Scots Statutes Revised (1707 to 1900)* in 10 volumes is a useful publication Obsolete Acts from 1424 to 1707 were repealed by the Statute Law Revision (Scotland) Act 1906

Ireland.—Originally the lord deputy appears to have held parliaments at his option, and their Acts were the only statutory law which applied to Ireland, except as far as judicial decisions had from motives of policy extended to that country the obligation of English statutes In 1495 the Act of the Irish parliament known as Poynings' Law or the Statute of Drogheda enacted that all statutes lately made in England be deemed good and effectual in Ireland This was construed to mean that all statutes made in England prior to the 18 Hen VII were valid in Ireland, but none of later date were to have any operation unless Ireland were specially named therein or unless adopted by the Irish parliament, as was done, for instance, by Yelverton's Act, 21 and 22 Geo III. c. 48 (I). Another article of Poynings' Law secured an initiative of legislation to the English privy council, the Irish parliament having simply a power of acceptance or rejection of proposed legislation. The power of the parliament of Great Britain to make laws to bind the people of Ireland was declared by 6 Geo I c. 5 This Act and the article of Poynings' Law were repealed in 1782, and the short-lived independence of the parliament of Ireland was recognized by 23 Geo III. c. 28 The application of Acts passed since the union is the same as in the case of Scotland Irish Acts are cited thus, 26 Geo. III. c. 15 (I) or (Ir) The best edition is that issued in 20 volumes pursuant to an order of the earl of Halifax, lord-lieutenant in 1762. A volume of revised statutes was published in 1885 The earliest that is still law is one of 1459. Since the constitutional changes in the Government of Ireland, the Irish Free State passes Acts printed bilingually and cited by year and number. The Northern Ireland legislation in form and citation resembles that of Westminster.

British Colonies, Dominions and Dependencies.—Acts of the imperial parliament do not extend to the Isle of Man, the Channel islands or the colonies, unless they are specially named therein. By the Colonial Laws Validity Act 1865 ("the charter of colonial legislative independence") any colonial law repugnant to the provisions of any Act of parliament extending to the colony is void to the extent of such repugnancy, and no colonial law is to be void by repugnancy to the law of England, unless it be re-

pugnant to such an Act of parliament. The 1865 Act is discussed in the Summary of Proceedings of the Imperial Conference of 1926 in its application to the self-governing dominions, for which the imperial parliament does not legislate without their consent. For colonies without representative legislatures the Crown usually legislates, subject to the consent of parliament in particular cases. Examples of imperial legislation for the colonies in general are the Colonial Stock Act 1877, and the Colonial Courts of Admiralty Act 1890. Imperial Acts dealing with particular dominions include the New Zealand Constitution Act 1852, the British North America Act 1867, the Commonwealth of Australia Constitution Act 1900, and the South Africa Act 1909: these statutes, like the Irish Free State Constitution Act 1922, deal with the competence of the dominion legislature. A colony is defined for the purposes of imperial legislation by the Interpretation Act 1889, s. 18. In certain dominions like Canada, the constitutionality of an Act of the colonial legislature is, as in the United States, a matter for the determination of the local court or of the judicial committee of the privy council on appeal.

Other Countries.—In most European countries there is a code, the existence of which makes the system of legislation hardly comparable to that of Great Britain. The assent of two chambers and of the president or other head of the State, is generally necessary.

The term "statute" is used by international jurists and civilians mostly on the continent of Europe to denote the whole body of the municipal law of the State. In this sense statutes are either real, personal or mixed. A real statute is that part of the law which deals directly with property, whether movable or immovable. A personal statute has for its object a person, and deals with questions of status, such as marriage, legitimacy or infancy. A mixed statute affects both property and person, or, according to some authorities, it deals with Acts and obligations. Personal statutes are of universal validity; real statutes have no extra-territorial authority. The determination of the class under which a particular law ought to fall is one of great difficulty, and one in which there is often a conflict of legal opinion.

See J. Story, *Conflict of Laws* (Boston, 1834; 8th ed. by H. M. Bigelow, 1883) ss. 12–16; von Bar, *Private International Law* (2nd ed., Eng. trans. by Gillespie, 1892); A. Pillet, *Traité Practique de droit international privé* (1924). (J. Wil.; C. T. C.)

UNITED STATES

Statute in American law is generally confined to an act of the legislature, though the term is occasionally used to apply to municipal ordinances and the rules and regulations of administrative agencies passed in the exercise of delegated legislative functions. The concurrence of the executive is demanded for the efficacy of the legislative act. The executive is accorded a veto over legislative action which can, however, be overridden by concurrence of a sufficient majority in the houses of the legislature.

Any consideration of statute-making in the United States must bear in mind the Federal character of the nation. Not only does each of the 48 States possess statute-making powers for that State, but the national Government within the ambit of its delegated powers may pass statutes effective throughout the nation. The device of judicial review over legislation is the scheme by which conflict between the various statutes is resolved. As the supreme law of the land stand the Constitution, treaties and laws of the United States, and State statutes passed in contravention of them are unenforceable. Not only are State and the lower Federal courts obliged to refuse to enforce a State statute contravening Federal constitutional or statutory law, but by providing for an appeal to the U.S. Supreme Court, the validity of State statutes can be brought for judgment to that ultimate tribunal. The Supreme Court thus occupies the position of arbiter in the eternal conflict between States and nation. State statutes must also comply with the provisions of the State Constitution but the final arbiter of their compliance is the State supreme court and not the U.S. Supreme Court. (*See* Constitution and Constitutional Law.) State statutes in violation of the State or Federal Constitution are void, but State statutes contravening Federal statutes are suspended during the operation of the latter.

The fact that there are 49 different statute-making bodies in the United States makes for an immense mass of legislation. Despite the fact that most State legislatures have only biennial sessions, their legislative activity produces a vast number of statutes. The first thorough attempt to keep in touch with their activity by the mechanism of an index to State legislation was originated in 1928 by the Library of Congress. Periodic revisions of their statutes are made by each State but upon plans that lack any uniformity. No revision of the statutes of the Federal Government was made until 1874. A second revision was accomplished in 1925.

Statutes commonly take effect from the date that they receive the executive assent. In some States constitutional provisions prescribe that they shall not be effective until after the expiration of a certain time after their passage, unless the legislature shall designate that the matter is one of such public urgency as to require their immediate operation. The result of these restrictions has been simply to induce the legislature to append an urgency clause to each statute irrespective of its subject-matter and thus override the constitutional restriction. Two other common constitutional provisions relative to statute-making in the State legislatures deserve notice. To avert the process of "log-rolling" or the inclusion of particular legislation in a general statute, the Constitutions provide that no statute shall deal with more than one subject, to be plainly and specifically expressed in the title to the act.

The legislation of the United States and its constituent States is generally conceded to be in an unhappy state. Several significant reform movements are (1929) in progress. A movement for the creation of legislative reference bureaux, organizations with the double purpose of offering expert help in the draughting of statutes and of affording to legislators information upon the subject matter of specific statutory proposals, was begun in Wisconsin and has gained wide acceptance during the last 15 years. Expert legislative draughtsmen are now attached to the Senate and House of the U.S. Congress and to a number of State legislatures. A movement for introducing uniformity in the statutory laws of the several States was initiated by the organization of the Commissioners on Uniform State Laws in 1892. They consist of commissioners appointed by each State who meet annually to frame legislation on subjects upon which uniformity is believed essential and recommend its enactment by the various State legislatures. Their most successful achievements have been in the field of commercial law, though their endeavours have embraced subjects of wide variety. Similar efforts to promote uniformity have been made by groups representing private interests and public welfare organizations. Interpretation statutes upon the British model have also been enacted in some States and the work of expert draughtsmen has brought some order and method in the process of statute-making.

Another peculiar American problem relates to the extent to which courts take cognizance of statute law. All courts are bound to take judicial notice of the Federal laws and the statutes of the State in which suit is brought. But different doctrines are in force as to the extent to which they will take notice of the statute law of other States. Some State courts have boldly asserted their willingness to take notice of such laws; others refuse to recognize them unless they are specially pleaded or proved, in default thereof assuming that the law of the other State is identical either with their decisional or statutory law.

Statutes have different forms, being either acts of the legislature or joint or concurrent resolutions of both houses of the legislature. In each instance they must secure the approval of the executive. In many cases the same subject-matter is alternately dealt with by both forms of statutes. Treaties of the national Government have the force of statutes and stand on a parity with them. Like statutes they are the "supreme law of the land" and supersede conflicting State legislation. Just as a subsequent statute may repeal an earlier one, a later statute repeals an earlier treaty. States are forbidden to conclude treaties but may make compacts with one another with the assent of Congress. Such compacts also have the effect of statutes. They have been used as an instrument of statecraft to deal effectively with problems that demand a

regional treatment greater than a single State can give and yet less than is desirable for nation-wide control

Codification on an analogy to the European systems began as a movement in 1848, the date of the adoption of the Field Code in New York. That code was limited to an attempt to recognize and simplify procedural law. A similar programme for the codification of the substantive law was initiated by the same sponsor, David Dudley Field, but failed of adoption. Procedural and substantive codes on the model of the Field Code were, however, adopted in numerous States. The merits and demerits of a codification in statutory form of the procedural and substantive law became a heated matter of professional controversy during the latter part of the 19th century The controversy has not yet abated The hopes of the codifiers of remodelling the common law on lines akin to the civil law systems have not been realized. Judges imbued with the common law training and technique have continued to handle codifications as mere statutes and not as ultimate sources of the law in the manner of the civilians. The "code States" are thus common law jurisdictions to the same extent as the other States.

See Freund, *Standards of American Legislation* (1917); Reinsch, *American Legislatures and Legislative Methods* (1913); Willard, *Legislative Handbook* (1890); Jones, *Statute Law Making in the United States* (1912); Sutherland, *Statutes and Statutory Construction* (1904); Black, *Handbook on the Construction and Interpretation of the Laws* (1911); Clarke, *Science of Law and Lawmaking* (1898); Brown, *Underlying Principles of Modern Legislation* (6th ed. 1920). (J M. LA.)

STATUTORY RULES AND ORDERS. The British parliament being a sovereign body, its acts cannot be challenged as *ultra vires*. "Statutory rules and orders," not passed directly by parliament but made under delegated powers, have no such immunity. Occasionally a statute, when authorizing such delegations, directs that the resultant rules, regulations or orders shall "have effect as if enacted in this Act." These words, formerly used by draftsmen when annexing schedules to statutes, may place the rules and orders beyond challenge (*Patent Agents Institute* v. *Lockwood,* 1894, A.C. 347), but normally the law courts will vigilantly examine the departmental exercise of legislative power. Law-making by statutory rules and orders was immensely extended during the World War, under the Defence of the Realm Acts, and is authorized by the Emergency Powers Act of 1920, when the community requires special protection The pressure upon parliamentary time is developing a system by which Acts contain bare principles of law, and the clothing of the skeleton is left to subordinate rule-making. The making of rules of procedure in various courts or Orders in Council (*see* PRIVY COUNCIL) to bring Acts into effect on appointed days are well-known instances of such delegated legislation. Special provisions exist for the publication of draft rules (*see* especially the limited effect of s 1 of the Rules Publication Act, 1893), for consultation with interests concerned, for control by parliament, and for the promulgation of all subordinate legislation when finally made.

See C T. Carr, *Delegated Legislation* (1921); J H. Morgan, *Remedies against the Crown* (1926); Lord Justice Sankey, *Principles and Practice of the Law To-day* (1928) (C. T C)

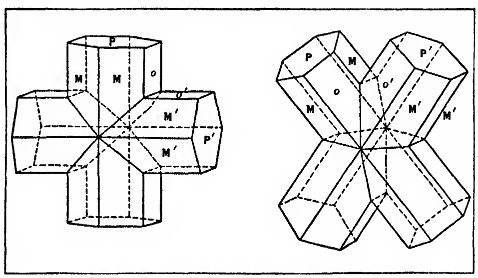
STAUNTON, HOWARD (1810–1874), English Shakespearian scholar and writer on chess, supposed to have been a natural son of Frederic Howard, fifth earl of Carlisle, was born in 1810 As a Shakespearian commentator he showed the qualities of acuteness and caution which made him excel in chess. He possessed, moreover, a thorough mastery of the literature of the period, shown in his papers in the *Athenaeum* on "Unsuspected Corruptions of Shakespeare's text," begun in October 1872. In 1864 he published a facsimile of the Shakespeare folio of 1623, and a facsimile edition of *Much Ado about Nothing,* photolithographed from the quarto of 1600 He died in London on June 22, 1874. Staunton's services to chess literature were very great, and the game in England owes much of its later popularity to him, while for thirty years he was the best player in England, perhaps in the world For his important works on the subject *see* CHESS.

STAUNTON, a city of Macoupin county, Illinois, U S A, 42 m. N.E. of Saint Louis. It is on Federal highway 66, and is served by the Wabash and the Illinois Traction (electric) railways, and for freight also by the Chicago and North Western and the Litchfield and Madison. Pop. 6,027 in 1920, 28% foreign-born white. Staunton is in the heart of a great coal-field and has several mines within its limits. The city was founded in 1830 and chartered in 1891.

STAUNTON (stăn'tọn), a city of Virginia, U S A, 1,385 ft. above sea-level, in the heart of the beautiful and fertile Shenandoah valley, 135 m N.W. of Richmond; the county seat of Augusta county, but administratively independent of it. It is on Federal highway 11 and is served by the Baltimore and Ohio and the Chesapeake and Ohio railways. Pop. 10,623 in 1920, 17% negroes; estimated locally at 12,500 in 1928. It is a city of beautiful residences and numerous schools and institutions The manse of the First Presbyterian church was the birthplace and childhood home of Woodrow Wilson About 20 m. S. of the city is the homestead of Cyrus McCormick, where he invented the reaper. Within 50 m. are five great caverns, Natural Bridge, and other points of interest. Just east of the city is a national cemetery, and west of it a Confederate cemetery. Staunton was the first city in America to adopt a city-manager form of government (1908).

The first settlement in the vicinity was made in 1731, 2 m E of the present city. A county court-house was built in 1745, and the name Staunton (the family name of the wife of Sir William Gooch) was adopted about 1748 In 1781, when Col. Tarleton drove the general assembly of Virginia across the Blue Ridge, they took refuge here, holding their sessions for a time in the old Trinity Episcopal church During the Civil War Staunton was an important supply-base for the army of northern Virginia and for Jackson's Valley campaign, and it was twice occupied by Federal troops It was chartered as a city in 1870

STAUROLITE, a mineral consisting of basic aluminium and ferrous iron silicate with the formula $HFeAl_5Si_2O_{13}$. The material is, however, usually very impure, the crystals enclosing sometimes as much as 30 or 40% of quartz and other minerals as well as carbonaceous matter Crystals are orthorhombic and have the form of six-sided prisms. Interpenetrating cruciform twinned crystals are very common and characteristic; they were early known as *pierres de croix* or *lapis crucifer,* and the name staurolite has the same meaning (Greek, σταυρός, a cross, and λίθος, a stone) In fig. 1 the twin-plane is (032) and the two prisms intercross



FIGS. 1 & 2.—TWIN CRYSTALS OF STAUROLITE

at an angle of 91° 22'; in fig 2 the twin-plane is (232) and the prisms intercross at nearly 60°. The mineral is translucent to opaque and dark reddish-brown in colour Waterworn pebbles of material sufficiently transparent for cutting as gem-stones are occasionally found in the diamantiferous sands of Brazil. The hardness is 7·5, specific gravity 3·75. Staurolite is a characteristic mineral of crystalline schists, and it is also a product of contact-metamorphism (L. J. S.)

STAVANGER, a seaport of Norway, capital of Stavanger *amt* (county), on the west coast on the Bukken fjord. Pop. (1921) 46,822 The town is one of the oldest in Norway, founded in the 8th or 9th century, but the greater part of the present town is modern and built of stone. It became the seat of a bishopric in the 13th century, and though the see was removed to Christian-

sand in 1685, it was restored in 1925. The cathedral church of St. Swithun, founded by the English bishop Reinald at the end of the 11th century, and rebuilt after being burned in 1272, is, next to the cathedral of Trondhjem, the most interesting stone church in Norway. The old episcopal palace of Kongsgaard is now a Latin school. The fisheries are important—for herring, mackerel, sprats, cod, salmon, lobsters and anchovies. The extraordinary growth of Stavanger during the last half century is mainly due to the development of its fish-canning industry. Other industries are the making of iodine from seaweed, and shipbuilding.

STAVELEY, town, in the north-eastern parliamentary division of Derbyshire, England, 12 m. S.E. of Sheffield, on the L.M.S. and L.N.E. railways. Pop. (1921) 12,646. It lies in the valley of the Rother, in a populous industrial district.

STAVELOT, town on the Amblève, province of Liége, Belgium. Pop. (1925) 5,724. Here Charles Martel gained a signal victory over Neustria in 719. The prince-abbot of the monastery of Stavelot (established 7th century) exercised secular authority over many towns in the Amblève and Warche valleys, including Malmédy, and had a seat in the old German Diet.

STAVROPOL, a former government of Russia, now in the Caucasian Area, North (*q.v.*).

STAVROPOL, a town of Russia, in the North Caucasian Area, in 45° N., 41° 58′ E., situated on a plateau 2,030 ft. above sea-level, on the northern slope of the Caucasus. The railway from Rostov-on-Don passes through it. Pop. (1926) 57,488. The town has textile and oil-pressing factories and manufactures agricultural machinery. It is a centre for Armenian, Georgian and Persian trade.

STAWELL, a municipality of Borung county, Victoria, Australia, 179 m. by rail W.N.W. of Melbourne. Pop. (1921) 4,413. The quartz reefs of the Pleasant Creek goldfields near the town are worked at very deep levels and there are cyanide plants.

STEAD, WILLIAM THOMAS (1849–1912), English journalist, was born at Embleton, Northumberland, on July 5, 1849, the son of a Congregational minister. He was early apprenticed in a merchant's office at Newcastle-on-Tyne; he soon gravitated, however, into journalism, and in 1871 became editor of the Darlington *Northern Echo.* In 1880 he went to London to be assistant editor of the *Pall Mall Gazette* under John Morley, and when the latter retired he became editor (1883–1889). Up to 1885 he had distinguished himself for his vigorous handling of public affairs, and his brilliant modernity in the presentation of news. He introduced the "interview," made a feature of the *Pall Mall* "extras" (*see* also NEWSPAPERS: *London*), and his enterprise and originality exercised a potent influence on contemporary journalism and politics. In 1885 he entered upon a crusade against vice by publishing a series of articles on the "Maiden Tribute of Modern Babylon." Though his action undoubtedly furthered the passing of the Criminal Law Amendment Act, it made his position on the paper impossible; and he was imprisoned in Holloway gaol for three months on a charge arising out of his crusade. On leaving the *Pall Mall* he founded the monthly *Review of Reviews* (1890). He started cheap reprints (*Penny Poets* and *Prose Classics,* etc.), conducted a spiritualistic organ, called *Borderland* (1893–1897), in which he gave full play to his interest in psychical research; and became an enthusiastic supporter of the peace movement, and of many other movements, popular and unpopular. He wrote with facility and sensational fervour on all sorts of subjects, from *The Truth about Russia* (1888) to *If Christ came to Chicago* (1893), and from *Mrs. Booth* (1900) to *The Americanization of the World* (1902). In private life his keen sense of merit and kindly interest influenced many aspirants to journalism and literature. Stead went down in the "Titanic" on April 15, 1912.

See *Life of W. T. Stead* (1913), by his daughter; and F. Whyte, *Life of W. T. Stead* (1925).

STEAM, the vapour of water. In the pure state it is a dry invisible gas. Often, however, as in a jet escaping from the spout of a kettle or the funnel of a locomotive, it is mixed with minute particles of water which are produced by condensation of portions of the gas. In such a mixture the suspended particles of water constitute a visible cloud. Any mixture of steam with water, whether in such a cloud or in the working chamber of an engine or turbine, is often spoken of as wet steam.

Its properties are most conveniently described by imagining an experiment in which steam is formed by applying heat to a small quantity of water contained at the bottom of a large upright cylindrical vessel. Suppose that the vessel is fitted with a piston which rests on the water to begin with and can rise when the fluid below it is made to change from water into steam by applying heat. Imagine further that the piston is frictionless and carries a definite weight so that, as the piston rises, the fluid continues to be subjected to a constant pressure, say, p lb. per square inch.

Saturated Steam.—When heat is applied, no steam is formed until the temperature of the water is raised to a value T which depends on p. Steam then forms, raising the piston, and this goes on without further rise of temperature until all the water is converted into steam, when it occupies a certain volume V. During this stage the steam is said to be *saturated.* T is the temperature of saturation corresponding to the pressure p, and is the lowest temperature at which steam can exist in stable equilibrium at that pressure.

Superheated Steam.—Suppose now, after all the water has turned into steam, that we go on applying heat. The temperature will rise and the volume will increase beyond V if we keep p constant, or the pressure will increase beyond p if we then fix the piston so as to keep V constant. In either case the steam is said to be *superheated.*

Steam is superheated when its temperature is raised in any manner to a value which exceeds the temperature of saturation corresponding to the actual pressure. Thus for example steam may change from the saturated to the superheated condition by being compressed (without loss of heat), or by passing (without loss of heat) through a throttle valve into a region of lower pressure. When steam is so "throttled" its temperature falls to some extent, but remains higher than the temperature of saturation corresponding to the reduced pressure.

Properties of Steam: Callendar's Tables.—The physical properties of steam have been the subject of systematic experimental enquiry by Regnault and many later observers. Our modern knowledge of them is largely due to H. L. Callendar who, with the help of formulas the basis of which is partly theoretical and partly empirical, has rationalized the experimental data and has compiled comprehensive tables for the use of engineers. Callendar's tables, published in 1915 and in an enlarged form in 1924, set forth all the important properties throughout a suitable range of pressures and temperatures. From the principles of thermodynamics (*q.v.*) it is known that certain relations hold between various properties, in steam or any other vapour; the values stated by Callendar, besides being founded on the best available data, are consistent with these relations. They apply to the superheated as well as to the saturated state; saturation is to be regarded as only a limiting case.

So long as steam is saturated the relation of temperature to pressure is definite. But steam may be superheated to any temperature above the saturation temperature at which it is formed in the boiling of water, and the temperature then becomes an independent variable. This affects certain other properties with which the steam engineer is concerned, namely:—

The volume V,
The internal energy E,
The total heat I,
The entropy ϕ,

all of which are to be reckoned per lb. of the substance. Each of these quantities has a definite value for steam or for water in any assigned state of pressure and temperature. Steam tables usually follow a convention, according to which quantities such as the energy or the entropy are treated as zero for water at 0° C; the tabulated numerical value accordingly expresses the amount by which the quantity in question has changed when the substance passes from that zero condition to the actual state.

Internal Energy.—When steam is formed (starting, say, from

the state of water at 0° C) heat is taken in, and some external work is done by the expansion of the substance. The difference, which depends simply on the final state and not on the manner of formation, is called the ***internal energy E***

Total Heat.—The total heat I is conveniently defined by the equation

$$I=E+APV,$$

where P and V are respectively the pressure and volume of the substance, and A is a factor which converts units of work into units of heat. Hence when the substance is heated under constant pressure the change of I is measured by the quantity of heat that is taken in, for it is then equal to the gain of internal energy plus the work done In a process of throttling it is easy to show that I does not change, provided there is no loss of heat to other bodies

Entropy.—To define entropy, it may be said that when the substance takes in heat in a reversible manner (namely a manner which excludes the existence of any turbulent movement) its entropy changes by the amount $\frac{Q}{T}$, where Q is the heat taken in and T is the temperature (on the absolute scale) at which it is taken in. If T is itself changing while the heat is being taken in, we must write this change of entropy as $\int\frac{dQ}{T}$. Thus when steam is formed in a quietly steaming boiler, at a constant temperature T, from water at the same temperature, the entropy ϕ changes by the quantity $\frac{L}{T}$, where L is the "latent heat." Like the other quantities, the entropy of water at 0° C is reckoned as zero for convenience in tabulation Both the entropy of steam and the total heat are quantities of great importance in the theory of the steam-engine (*q v*)

Critical Temperature.—Imagine a quantity of superheated steam at any usual temperature to be compressed while the temperature is kept constant When the pressure reaches a certain value condensation begins, and we are then dealing with a substance which is partly water and partly saturated steam The pressure in question is that which corresponds to saturation at the assumed constant temperature This pressure will not rise further until all is condensed. after that the pressure on the water may of course be increased to any extent The process is discontinuous, with three distinct stages Suppose this experiment to be repeated at various temperatures it will be found that when the temperature is sufficiently high there is no stage during which both water and steam are present together When this temperature is reached or exceeded, the substance passes, as its pressure is increased, from the condition of steam to that of water—from vapour to liquid—in a continuous manner without ever being a mixture of the two The lowest temperature at which this can happen is called the *critical Temperature,* and the limit of pressure above which the substance cannot exist as a non-homogeneous mixture of liquid and vapour is called the *critical Pressure* These conditions of pressure and temperature constitute the "critical point." The critical temperature of steam is about 374° C and the critical pressure about 3,158 lb. per square inch

The properties of steam in the neighbourhood of the critical point are less exactly known than at lower and more usual pressures The "characteristic equation" on which Callendar founds many of his tabulated values applies with sufficient exactness within the lower range of pressures commonly met with in engineering practice It takes the form

$$V = \frac{RT}{P} - c + b,$$

where V is the volume (per lb), T is the absolute temperature, P is the pressure, R is a constant relating to the ideal volume of a "perfect" gas, b is a constant which expresses the additional volume of the molecules, and c is a term, depending on the temperature, which expresses the loss of volume through "coaggregation" or temporary association of molecules. The equation is applicable to the superheated as well as the saturated state

Super-saturation.—When steam is cooled to a temperature at which condensation should occur, it is found, when no nuclei are present about which water droplets may form, that the temperature may fall some way below the temperature of saturation before condensation begins A temporary and unstable state may accordingly be produced, called *super-saturation* The vapour in this condition may be described as supercooled its state is analogous to that of a liquid cooled below its melting point without crystallization

Water-vapour in Air.—Water vapour is one of the constituents of the atmosphere, the proportion depending not only on the temperature but on other causes which affect local dryness At any given temperature air is said to be saturated with water vapour when the proportion present is such as to exert a partial pressure equal to the pressure of saturation corresponding to the given temperature Any excess tends to be thrown out as mist or rain. any less quantity than that required for saturation is held as an invisible constituent, namely, in the state of superheated steam The quantity of water-vapour present in air may be expressed as a fraction of the quantity which would cause saturation: this fraction is called the "relative humidity" of the air. The "dew-point" is the temperature to which air must be cooled to allow a deposit of water to take place

Air is often dried for industrial uses by cooling it to a very low temperature This causes it to deposit nearly all its contained moisture, which is then drained away, leaving only the trifling quantity that suffices to produce saturation at the low temperature When the air returns to normal temperature without taking up more water its relative humidity is very small

(J A E)

STEAM ACCUMULATORS are devices for equalizing steam flow and steam demand They are inserted between the source of steam supply and the point where it is used for the purpose of absorbing steam at times of low demand and releasing it when needed, several types have been developed One of the earliest was the Rateau accumulator or regenerator Its primary purpose was to utilize the intermittent exhaust from prime movers—such as steel rolling-mill engines—for driving low-pressure turbines carrying a fairly constant load; installed in the steam line between these two units, it served to equalize supply and demand, the turbine governor being designed to admit live steam when necessary Another type is the Smoot accumulator, designed primarily for use in gas manufacturing plants It collects, or accumulates, in a steel tank the exhaust from pumps and auxiliaries and from the

FIG 1—MECHANICAL DRAWING OF A COMPLETE ACCUMULATOR INSTALLATION

hot-water drips; by decreasing the pressure in this tank steam is made available for the intermittent operation of the water-gas apparatus, and deficiency in supply is taken care of by a live steam "make-up" valve The latest development is known as the Ruths steam accumulator, and while it operates on the same general principle as the others, it has been applied over a wider field of usefulness. Specially designed governor valves make its operation entirely automatic up to 200 lb. per sq in. and through greater pressure ranges (fig. 1). The tank A is filled with water to 90% of its capacity, and the regulating valves V-*1* and V-*2* automatically control the charging and discharging of the accumu-

lator. The accumulator must be placed between the high and the low pressure steam line, and its pressure varies between these limits; accumulated steam is made available by the regulating valves in such a way as to maintain uniform steam pressures in the low pressure steam lines. Any steam generated by the boilers and not used by the high pressure consumers overflows through valve *V-1* into the accumulator. *V-2* maintains a uniform pressure in the line *P* carrying the low pressure steam, so that if the valve *V-1* is passing more steam than is required in the low pressure line, the excess is stored in the accumulator. Charging nozzles *G* are equipped with circulating pipes *H* which permit a uniform and noiseless heating of the water. Should a sudden demand for high pressure steam arise the boiler pressure would drop slightly, *V-1* would close and a certain amount of steam would become available at or near this higher pressure. This diversion to the high pressure line of steam intended for the lower pressures would cause a deficit in the low pressure line. *V-2* would then open and the heat energy previously stored in the accumulator would instantly flash into steam to meet this deficit. Should the sudden increase in demand be caused by low pressure consumption and the flow through *V-1* not sufficient, the accumulator would supply it. (R. A. L.)

STEAM-CHEST is a box cast on or attached to the side of a steam cylinder, and containing the slide-valve which slides over the steam and exhaust ports, and uncovers these in turn. A stuffing-box maintains the valve-rod steam-tight. Some engines have two valves, one sliding upon the top of the other, for the purpose of giving expansive working of the steam. Cylindrical or piston valves are used extensively in marine and locomotive cylinders, as they give a balanced effect all around. In locomotive practice these valves have to be placed above the cylinders in many cases for reasons of design.

STEAM COAL: *see* COAL AND COAL MINING.

STEAM ENGINE. A steam engine is a heat engine in which the working substance is steam. By a heat engine is meant a machine for doing mechanical work through the agency of heat: it does this by taking in heat at comparatively high temperature, converting part of the heat into another form of energy, and rejecting the remainder of the heat at a lower temperature. The working substance is the vehicle by which heat is taken in and rejected. In a steam engine, the substance takes in heat mainly in a separate vessel—the boiler—in the process of being vaporized; it does work by expanding under pressure and thereby converts part of the heat that is taken in; finally the remainder of the heat is rejected, either by allowing the steam to escape into the atmosphere, as in locomotives, or by condensing it at a comparatively low temperature and pressure, as in marine and many other engines. This gives a broad distinction between non-condensing and condensing steam engines. The latter have the great advantage that they allow the effective expansion of the steam to be carried much farther; the substance rejects heat at a lower limit of temperature, and this enables the engine to convert into work a larger fraction of the heat which it has received. That fraction expresses what is called the *efficiency* of the engine as a contrivance for converting heat into work. The addition of a condenser, while it increases the efficiency, of course complicates the mechanism: it requires a supply of cooling water or some equivalent means of keeping down the temperature by absorbing the heat which the steam gives up in the act of being condensed, and also a pump or other means of removing the condensed substance together with any air that may be present. But the advantage which it brings about in respect of efficiency is so great that all engines of large power, where economy of fuel is an important factor, and where the use of a condenser is practicable, are of the condensing kind.

Given the upper limit of temperature, at which heat is taken in, the efficiency which the engine may attain is determined by the lowness of the temperature at which heat is rejected. Similarly, when the lower limit of temperature, at which heat is rejected, is assigned, the efficiency which the engine may attain is increased by raising the temperature at which the working substance takes in heat. To secure high efficiency there must be a wide range through which the temperature of the working substance falls, as a consequence of expansion within the engine, from the level of temperature at which heat is received to the level at which heat is rejected. Thus in the steam engine the most efficient performance, that is to say the greatest output of work in relation to the heat supplied, is secured by keeping the condenser as cold as the available cooling water will allow, and at the same time using a high boiler pressure, so that the working substance is very hot while it receives heat in the act of changing from water into steam. For this reason, modern practice tends towards higher and higher boiler pressures, as the mechanical difficulties of boiler construction and high pressure working are overcome.

After conversion into steam the working substance may take in a supplementary supply of heat on its way from the boiler to the engine, by passing through a *superheater,* in which its temperature is raised above that of the boiler. A common form of superheater is a group of parallel pipes with their surfaces exposed to hot gases of the boiler furnace.

Steam engines are classified into two general types according to the manner in which the steam does work during its expansion. In the first, or piston-and-cylinder type, the steam, in a confined space, namely the part of the cylinder behind the piston, enlarges the volume of that space by pushing the piston forward. It does work by exerting a static pressure on the moving piston: the movement of the steam itself is of no significance. In the second class, to which belong all kinds of steam turbines, the action is less direct. The pressure of the steam is first employed to set the steam itself into motion, forming a jet or group of jets, the momentum of which causes work to be done on a moving part of the machine, either by the impulsive action of the jet or jets on revolving vanes, or by the reaction on revolving guide-blades during the formation of the jets, or, as in Parsons' turbine, by a combination of impulse and reaction. In any turbine the action of the steam is kinetic, in contrast with its static action in an engine of the piston type. In both types there is progressive expansion of the steam from the high pressure and relatively small volume at which it is admitted, to the low pressure and relatively very great volume at which it is discharged. The principle already stated, that a large range of temperature and pressure, between admission and exhaust, is essential to efficiency applies equally to both types. In practice, the turbine has a notable advantage over the piston-and-cylinder engine in this respect, that it allows the last stages of the expansion, when the volume of the steam has become very great, to be effectively utilised, to a degree which is impracticable in the other type, because of the enormous size which the cylinder would have to assume and the waste of work that would be caused by piston friction, if the steam were expanded down to a very low pressure by the piston method. The turbine method escapes these difficulties; mainly for that reason it has become the most efficient way of converting heat into work, on a large scale, through the agency of steam. It has further advantages in compactness, in simplicity of working, and in the facility with which it can be adapted to take steam of exceptionally high initial pressure and high superheat.

HISTORICAL

In any historical sketch of the steam-engine, stress must be laid on the work of James Watt. But a process of evolution had been going on before his time which prepared a crude and primitive device for the immense improvements it received at his hands. The labours of Watt stand in natural sequence to those of Newcomen, and Newcomen's to those of Papin and Savery. Savery's engine, in its turn, was the reduction to practical form of an ancient scientific toy. Along another line of development, the modern steam turbine, which we owe to the genius of Charles Parsons, can be traced back to an early prototype.

In the *Pneumatica* of Hero of Alexandria (*c.* 130 B.C.) there is described the aeolipile, which may be called a primitive steam reaction turbine. It consists of a hollow globe pivoted so that it can turn on a pair of central trunnions, and supplied with steam through one of them, which is hollow. The steam escapes from the globe to the outside air through two bent pipes facing tan-

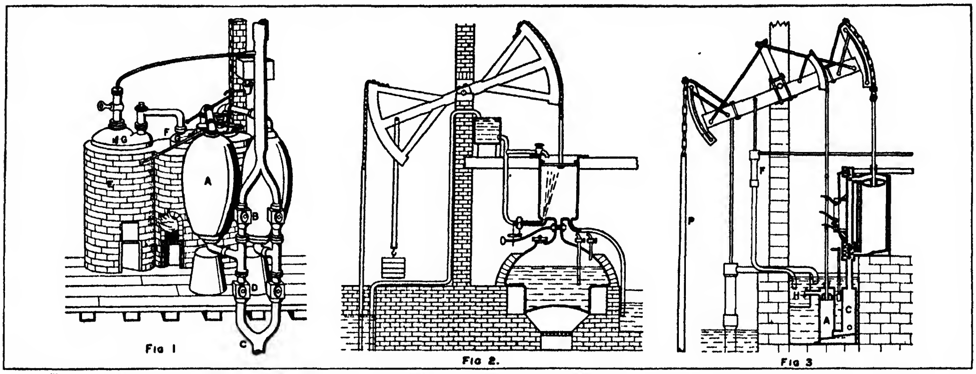

FIG. 1. SAVERY'S STEAM ENGINE (1698). FIG. 2. NEWCOMEN AND CAWLEY STEAM ENGINE (1705). FIG. 3. THE WATT PUMPING ENGINE

gentially in opposite directions at the ends of a diameter perpendicular to the axis The globe revolves by reaction from the escaping steam Hero's volume also mentions (Greenwood's translation of Hero's *Pneumatica*) another device which may be described as the prototype of the pressure engine. A hollow altar containing air is heated by kindling a fire on it; the air expands and by its pressure drives some of the water in a vessel below into a hanging bucket, which then descends, opening the doors of a shrine. When the fire is extinguished the air contracts, the bucket empties, and the doors close.

In a treatise on pneumatics (1601) by Giovanni Battista della Porta there is shown a somewhat similar apparatus, but with steam for working substance. Its pressure forces up water from a separate vessel He also points out that the condensation of the steam may be used to produce a vacuum and thereby suck up water from a lower vessel. His suggestions go far to anticipate the engine which, a century later, in the hands of Savery, became the first commercially successful steam engine

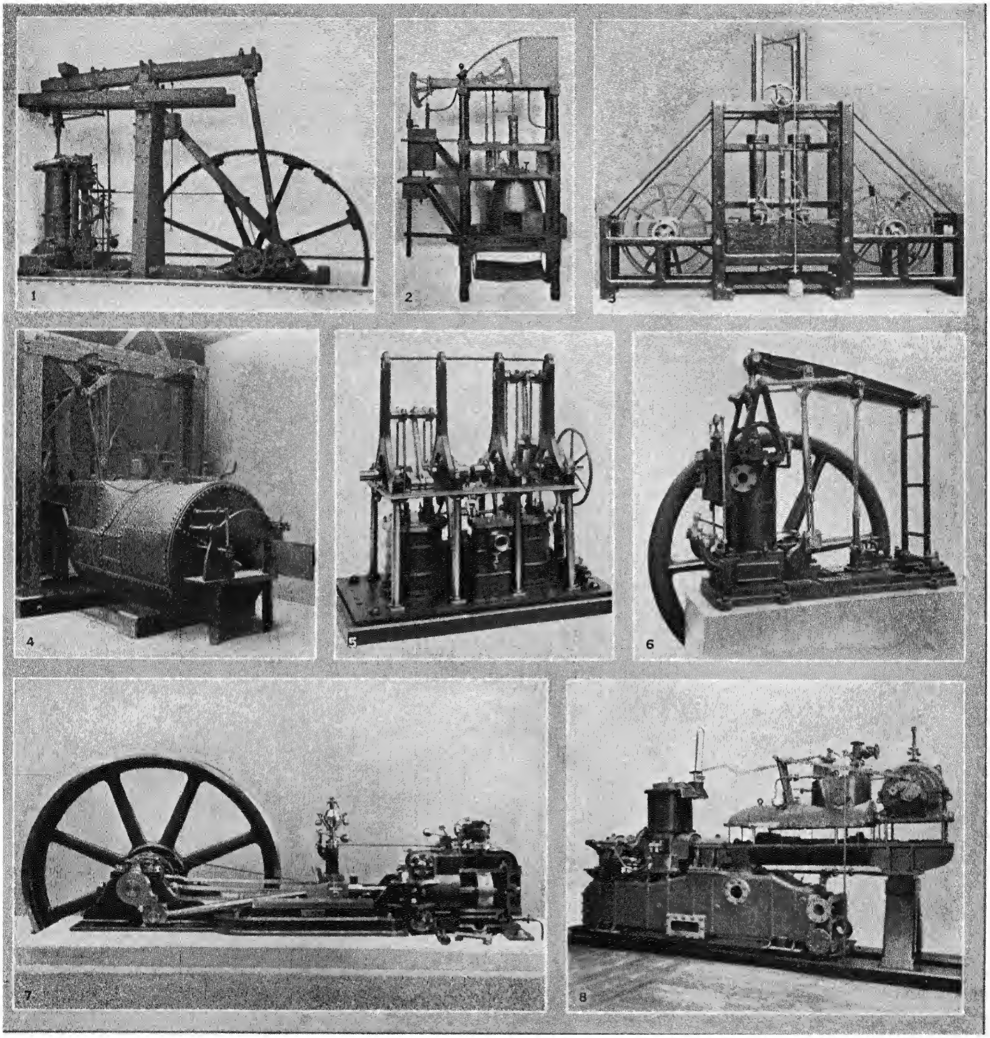
Meanwhile Edward Somerset, second Marquis of Worcester, described in his *Century of Inventions* (1663) a method of raising water by the agency of steam. His description is obscure, and no drawings of the device are extant. It appears to have consisted of a pair of displacement chambers, from each of which alternately water was forced, probably by admitting steam from an independent boiler, while the other vessel was allowed to refill.

Savery, 1698.—The earliest steam-engine to take a practical form and find employment in industry was that of Thomas Savery, who, in 1698, obtained a patent for a water-raising engine, shown in fig. 1. Steam is admitted to one of the oval vessels *A*, displacing water, which it drives up through the check-valve *B*. When the vessel *A* is emptied of water the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel This produces a vacuum and causes water to be sucked up through the pipe *C* and the valve *D*. Meanwhile steam has been displacing water from the other vessel, and is ready to be condensed there. The valves *B* and *D* open only upwards. The supplementary boiler and furnace *E* are for feeding water to the main boiler; *E* is filled while cold and a fire is lighted under it; it then forces a supply of feeding-water into the main boiler *F*. The gauge cocks *G*, *G* are an interesting detail. Another form of Savery's engine had only one displacement-chamber and worked intermittently. In the use of artificial means to condense the steam, and in the application of the vacuum so formed to raise water by suction from a level lower than that of the engine, as well as in practical features, Savery's engine marked an inventive advance. It found considerable employment in pumping mines and in raising water to supply houses and towns, and even to drive water-wheels. A serious difficulty which prevented its general use in mines was the fact that the height through which it would lift water was limited by the pressure the boiler and vessels could bear. Pressures as high as 8 or 10 atmospheres were employed—and that, too, without a safety-valve—but Savery found it no easy matter to deal with high-pressure steam. Apart from this drawback, the waste of fuel was enormous, from the condensation of steam which took place on the surface of the water and on the sides of the displacement-chamber at each operation; the consumption of coal was, in proportion to the work done, some twenty times greater than in a modern engine.

Before Savery's engine was displaced by its successor, Newcomen's, it was improved by J. T Desaguliers who applied to the safety valve (invented by Papin), and substituted condensation by a jet of cold water within the vessel for the surface condensation used by Savery To Savery is ascribed the first use of the term "horse-power" as a measure of performance.

In 1690 Denis Papin suggested that the condensation of steam should be employed to make a vacuum under a piston previously raised by the expansion of the steam. Papin's was the earliest cylinder and piston steam engine, and his plan of using steam was that which afterwards took practical shape in the atmospheric engine of Newcomen. But his scheme was made unworkable by the fact that he proposed to use but one vessel as both boiler and cylinder. A small quantity of water was placed at the bottom of a cylinder and heat was applied. When the piston had risen the fire was removed, the steam was allowed to cool, and the piston did work in its down-stroke under the pressure of the atmosphere After hearing of Savery's engine in 1705 Papin turned his attention to improving it, and devised a modified form, with a floating diaphragm or piston on the top of the water to keep the water and steam from direct contact with one another Papin's engine may be described as a non-condensing single-acting steam pump, with steam cylinder and pump cylinder in one.

Newcomen's Atmospheric Engine, 1705.—While Papin was thus going back from his first notion of a piston engine to Savery's cruder type, a new inventor had appeared who made the piston engine a practical success by separating the boiler from the cylinder and by using (as Savery had done) artificial means to condense the steam. This was Thomas Newcomen, who in 1705, with his assistant, John Cawley, gave the steam engine the form shown in fig. 2. Steam admitted from the boiler to the cylinder by the opening of a valve allowed the piston to be raised by a heavy counterpoise on the other side of the beam. Then the steam valve was shut and a jet of cold water entered the cylinder and condensed the steam. The piston was consequently forced down by the pressure of the atmosphere and did work on the pump. The next entry of steam expelled the condensed water from the cylinder through an escape valve. The piston was kept tight by a layer of water on its upper surface. Condensation was at first effected by cooling the outside of the cylinder, but an accidental leakage of the packing water past the piston showed the advantage of condensing by a jet of injection water, and this plan took the place of surface condensation. The engine used



THE PROGRESS OF THE STEAM ENGINE

1. One of Boulton and Watt's early (1789) rotative steam engines, among the first to utilize the double-acting principle
2. Model of Newcomen's steam engine (1719), the precursor of Watt's engine, and successfully used in pumping and mine drainage. Newcomen created a vacuum within the cylinder by the condensation of steam
3. Symington's original marine steam engine (1788), first used to propel a paddle-boat on Dalswinton Loch, Scotland, at a speed of about 4 m. per hour
4. Trevithick's high-pressure, or non-condensing engine (1811)
5. Quadruple piston-rod steeple paddle engine (1842)
6. Grasshopper engine (1862), so-called because of the obvious resemblance of its upper and right-hand portions to that insect
7. Model of single-cylinder horizontal engine (1898), with Corliss valve gear. A sectional view at the right end of cylinder reveals the piston and valve construction
8. Parsons' turbo-generator (1902), with upper turbine casing lifted to show rotor

steam whose pressure was little if at all greater than that of the atmosphere.

About 1711 Newcomen's engine began to be introduced for pumping mines. It is doubtful whether the action was originally automatic, or depended on the periodical turning of taps by an attendant. The common story is that in 1713 a boy named Humphrey Potter, whose duty it was to open and shut the valves of an engine he attended, made the engine self-acting by causing the beam itself to open and close the valves by suitable cords and catches. This device was simplified in 1718 by Henry Beighton, who suspended from the beam a rod called the plug-tree, which worked the valves by means of tappets. By 1725 the engine was in common use in collieries, and it held its place without material change for about three-quarters of a century in all. Near the close of its career Newcomen's engine was much improved in its mechanical details by John Smeaton, who built many large engines of this type about the year 1770, just after the great step which was to make Newcomen's engine obsolete had been taken by James Watt.

Compared with Savery's engine, Newcomen's had (as a pumping engine) the great advantage that the intensity of pressure in the pumps was not in any way limited by the pressure of the steam. It shared with Savery's, in a scarcely less degree, the defect already pointed out, that steam was wasted by the alternate heating and cooling of the vessel into which it was led. Though obviously capable of more extended uses, it was in fact almost exclusively employed to raise water—in some instances for the purpose of turning water-wheels to drive other machinery. Even contemporary writers complain of its great consumption of fuel.

James Watt, 1763, 1769, 1781, etc.—In 1763 James Watt, an instrument maker in Glasgow, while engaged by the University in repairing a model of Newcomen's engine, was struck with the waste of steam to which the alternate chilling and heating of the cylinder gave rise. He saw that the remedy, in his own words, would lie in keeping the cylinder as hot as the steam that entered it. With this view he added to the engine a new organ—namely the "separate condenser"—an empty vessel separate from the cylinder, into which the steam should be allowed to escape from the cylinder, to be condensed there by the application of cold water either outside or as a jet. To preserve the vacuum in his condenser he added a pump called the air pump, whose function was to extract from it the condensed steam and water of condensation, as well as any air which might come in by leakage or by solution in the steam or the injection water. Then, as the cylinder was no longer used as a condenser, he was able to keep it hot by clothing it with non-conducting bodies, and in particular by the use of what is called a steam-jacket—a layer of hot steam between the cylinder and an external casing. Further and still with the same object, he covered in the top of the cylinder, taking the piston-rod out through a steam-tight gland or stuffing-box, and allowed steam instead of air to press upon the piston's upper surface. After much experiment Watt patented his improvements in 1769; they are described in a specification from which the following extracts are taken:—

"My method of lessening the consumption of steam, and consequently fuel, in fire-engines, consists of the following principles:—

"*First*, That vessel in which the powers of steam are to be employed to work the engine, which is called the cylinder in common fire-engines, and which I call the steam vessel, must, during the whole time the engine is at work, be kept as hot as the steam that enters it; first by inclosing it in a case of wood, or any other materials that transmit heat slowly; secondly, by surrounding it with steam or other heated bodies; and, thirdly, by suffering neither water nor any other substance colder than the steam to enter or touch it during that time.

"*Secondly*, In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensed in vessels distinct from the steam-vessels or cylinders, although occasionally communicating with them; these vessels I call condensers; and, whilst the engines are working, these condensers ought at least to be kept as cold as the air in the neighbourhood of the engines, by application of water or other cold bodies.

"*Thirdly*, Whatever air or other elastic vapour is not condensed by the cold of the condenser, and may impede the working of the engine, is to be drawn out of the steam-vessels or condensers by means of pumps, wrought by the engines themselves, or otherwise.

"*Fourthly*, I intend in many cases to employ the expansive force of steam to press on the pistons, or whatever may be used instead of them, in the same manner in which the pressure of the atmosphere is now employed in common fire-engines. In cases where cold water cannot be had in plenty, the engines may be wrought by this force of steam only, by discharging the steam into the air after it has done its office."

The "common fire-engine" alluded to was the steam engine of Newcomen. Highly important as Watt's first inventions were, they resulted for a time in the production of nothing more than a greatly improved engine of the Newcomen type, much less wasteful of fuel, able to make faster strokes, but still only suitable for pumping, still single-acting, with steam admitted during the whole stroke, the piston, as before, pulling the beam by a chain working on a circular arc. The condenser was generally worked by injection, but Watt has left a model of a surface condenser made up of small tubes, in every essential respect like the condensers now used.

Fig. 3 is an example of the Watt pumping engine of this period. It should be noticed that, although the top of the cylinder is closed, and steam has access to the upper side of the piston, this is done only to keep the cylinder and piston warm. The engine is still single-acting; the steam on the upper side merely plays the part which was played in Newcomen's engine by the atmosphere; and it is the lower end of the cylinder alone that is ever put in communication with the condenser. There are three valves: the "steam" valve *a*, the "equilibrium" valve *b*, and the "exhaust" valve *c*. At the beginning of the down-stroke *c* is opened to produce a vacuum below the piston and *a* is opened to admit steam above it. At the end of the down-stroke *a* and *c* are shut and *b* is opened. This puts the two sides in equilibrium and allows the piston to be pulled up by the pump-rod P, which is heavy enough to serve as a counterpoise. C is the condenser, and A is the air-pump, which discharges into the hot well H, whence the supply of the feed-pump F is drawn.

In a second patent (1781) Watt describes the "sun-and-planet" wheels and other methods of making the engine give continuous revolving motion to a shaft provided with a flywheel. The crank and connecting-rod—already a familiar mechanical device from its use on the treadle of a lathe—would have been the natural means of doing this, but its application to the steam engine in a particular manner had been made the subject of a patent by James Pickard, and Watt, rather than make terms with Pickard, whom he regarded as a plagiarist of his own ideas, made use of his sun-and-planet motion until the patent on the crank expired. The reciprocating motion of earlier forms had served only for pumping; by making the steam engine drive a revolving shaft Watt opened up for it many other channels of usefulness. The engine was still single-acting; the connecting-rod was attached to the far end of the beam, and that carried a counterpoise which served to raise the piston when steam was admitted below it.

In 1782 Watt patented two further improvements of the first importance, both of which he had invented some years before. One was the use of double action, that is to say, the application of steam and vacuum to each side of the piston alternately. The other (invented as early as 1769) was the use of steam expansively, in other words the plan, essential to economy of fuel, of stopping the admission of steam when the piston had made only a part of its stroke, and allowing the rest of the stroke to be performed by the expansion of the steam already in the cylinder. To let the piston push as well as pull the end of the beam Watt devised his so-called parallel motion, an arrangement of links connecting the piston-rod head with the beam in such a way as to guide the rod to move in a very nearly straight line. He further added a throttle valve, for regulating the rate of admission of steam, and a centrifugal governor, in the form of a double conical pendulum, which controlled the speed by a throttle-valve.

Among other important devices associated with Watt was the "indicator," by which diagrams showing the relation of the steam pressure in the cylinder to the movement of the piston are automatically drawn: its invention seems to have been mainly due to his assistant John Southern.

In partnership with Matthew Boulton, Watt carried on in Birmingham the manufacture and sale of his engines with great success, and held the field against all rivals in spite of severe assaults

on the validity of his patents Notwithstanding his knowledge of the advantage to be gained by using steam expansively, he continued to employ only low pressures—seldom more than 7 lb. per square inch over that of the atmosphere. His boilers were fed, as Newcomen's had been, through an open pipe which rose high enough to let the column of water in it balance the pressure of the steam. He gave a definite numerical significance to the term "horse-power," defining it as the rate at which work is done when 33,000 lb are raised one foot in one minute

In the fourth claim of Watt's first patent, quoted above, the second sentence describes a non-condensing engine, which would have required steam of a higher pressure. This, however, was a line of invention which Watt did not follow up, perhaps because so early as 1725 a non-condensing engine had been described by Jacob Leupold in his *Theatrum machinarum.*

It was not till much later that the thermodynamic principles underlying the action of the steam engine came to be understood Engineers were consequently slow to appreciate the fact that to obtain economy of fuel it was advantageous to employ a high initial pressure, in combination with much expansion in the cylinder and with the separate condenser of Watt.

Trevithick, Bull and Evans.—The introduction of the non-condensing and, at that time, relatively high-pressure engine was effected in England by Richard Trevithick and in America by Oliver Evans about 1800 Both Evans and Trevithick applied their engines to propel carriages on roads, and both used for boiler a cylindrical vessel with a cylindrical flue inside containing the fire —the construction now known as the Cornish boiler In association with Edward Bull, Trevithick had previously made direct acting pumping-engines, with an inverted cylinder set over and in line with the pump-rod, thus dispensing with the beam that had been a feature in all earlier forms But in these "Bull" engines, as they were called, the steam was condensed by a jet of cold water in the exhaust-pipe, and Boulton and Watt successfully opposed them as infringing Watt's patent To Trevithick belongs the honour of being the first to use a steam carriage on a railway; in 1804 he built a locomotive in the modern sense, to run on what had formerly been a horse-tramway, in Wales In this connection it may be added that as early as 1769 a steam carriage for roads had been built in France by Nicolas Joseph Cugnot, who used a pair of single-acting high-pressure cylinders to turn a driving axle step by step by means of pawls and ratchet-wheels To the initiative of Evans may be ascribed the early general use of high-pressure steam in the United States, a feature which for many years distinguished American from English practice (*See* LOCOMOTIVE)

Compound Engine and Cornish Engine.—Among contemporaries of Watt the name of Jonathan Hornblower deserves special mention. In 1781 he constructed and patented what would now be called a compound engine, with two cylinders of different sizes Steam was first admitted into the smaller cylinder, and then passed over into the larger, doing work against a piston in each. In Hornblower's engine the two cylinders were placed side by side, and both pistons worked on the same end of a beam overhead. This was an instance of the use of steam expansively, and as such was earlier than the patent, though not earlier than the invention, of expansive working by Watt Hornblower was crushed by the Birmingham firm for infringing their patent in the use of a separate condenser and air-pump The compound engine was revived in 1804 by Arthur Woolf, with whose name it is often associated. Using steam of fairly high pressure, and cutting off the supply before the end of the stroke in the small cylinder, Woolf expanded the steam to several times its original volume. Mechanically the two-cylinder compound engine has some advantage over a one-cylinder engine with the same amount of expansion, in exerting a more uniform driving effort But another and more important merit of the system lies in the fact that by dividing the whole range of expansion into two parts the cylinders in which these are separately performed are subject to a reduced range of fluctuation in their temperature This helps to limit a source of waste which is present in all piston engines, namely the waste which results from the heating and cooling of the metal by its alternate contact with hot and cooler steam. The introduction of compound expansion forms the most outstanding improvement which steam engines of the piston and cylinder type have undergone since the time of Watt

Woolf introduced the compound engine somewhat widely about 1814 as a pumping engine in the mines of Cornwall But here it met a strong competitor in the high-pressure single-cylinder engine of Trevithick, which had the advantage of greater simplicity in construction Woolf's engine fell into comparative disuse, and the single-cylinder type took a form which, under the name of the Cornish pumping-engine, was for many years famous for its great economy of fuel. In this engine the cylinder was set under one end of a beam, from the other end of which hung a heavy rod which operated a pump at the foot of the shaft Steam was admitted above the piston for a short portion of the stroke, thereby raising the pump-rod, and was allowed to expand for the remainder Then an equilibrium valve, connecting the space above and below the piston, as in fig 3, was opened, and the pump-rod descended, doing work in the pump and raising the engine piston The large mass which had to be started and stopped at each stroke served by its inertia to counterbalance the unequal pressure of the steam, for the ascending rods stored up energy of motion in the early part of the stroke, when the steam pressure was greatest, and gave out energy in the later part, when the pressure was much lowered by expansion The frequency of the stroke was controlled by a device called a cataract, consisting of a small plunger pump, in which the plunger, raised at each stroke by the engine, was allowed to descend more or less slowly by the escape of fluid below it through an adjustable orifice, and in its descent liberated catches which held the steam and exhaust valves from opening A similar device controlled the equilibrium valve, and could be set to give a pause at the end of the piston's down-stroke, so that the pump-cylinder might have time to become filled.

The final revival of the compound engine did not occur until about the middle of the 19th century, and then several agencies combined to effect it. In 1845 John M'Naught introduced a plan of improving beam engines of the original Watt type, by adding a high-pressure cylinder whose piston acted on the beam between the centre and the fly-wheel end Steam of higher pressure than had formerly been used, after doing work in the new cylinder, passed into the old or low-pressure cylinder, where it was further expanded Many engines whose power was proving insufficient for the extended machinery they had to drive were "M'Naughted" in this way, and after conversion were found not only to yield more power but to show a marked economy of fuel The compound form was selected by William Pole for the pumping engines of Lambeth and other waterworks about 1850, in 1854 John Elder began to use it in marine engines; in 1857 E A Cowper added a steam-jacketed intermediate reservoir for steam between the high- and low-pressure cylinders, which made it unnecessary for the stroke of the low-pressure piston to be just beginning when that of the other piston was just ending As facilities increased for the use of high-pressure steam, compound expansion came into more general use, its advantage becoming more conspicuous with every increase in boiler pressure. In marine practice, where economy of fuel was from the first an obviously important factor in design, the principle of compound expansion was extended by the introduction of triple and even quadruple expansion engines.

Application to Locomotives and Steamboats.—The adaptation of the steam engine to railways, begun by Trevithick, became a success in the hands of George Stephenson, whose engine, the "Rocket," when tried along with others in 1829, distanced its competitors The principal features of the "Rocket" were an improved steam-blast for urging the combustion of coal and a boiler (suggested by Henry Booth) in which a large heating surface was given by the use of many small tubes through which the hot gases passed Further, the cylinders, instead of being vertical as in earlier locomotives, were set at a slope, which was afterwards altered to a position more nearly horizontal. To these features there was added later the "link motion," a contrivance which enabled the engine to be easily reversed, and the amount of expansion to be readily varied. In the hands of George Stephenson

and his son Robert the locomotive took a form which in the main is retained by the far heavier locomotives (*q.v.*) now in use.

The first practical steamboat was the tug "Charlotte Dundas," built by William Symington, and tried in the Forth and Clyde canal in 1802. A Watt double-acting condensing engine, placed horizontally, acted directly by a connecting-rod on the crank of a shaft at the stern, which carried a revolving paddle-wheel. The trial was successful, but steam towing was abandoned for fear of injuring the banks of the canal. Ten years later Henry Bell built the "Comet," with side paddle-wheels, which ran as a passenger steamer on the Clyde; but an earlier inventor to follow up Symington's success was the American, Robert Fulton, who, after unsuccessful experiments on the Seine, fitted a steamer on the Hudson in 1807 with engines made to his designs by Boulton and Watt, and brought steam navigation for the first time to commercial success.

Rise in Steam Pressure and in Piston Speed.—With improvements in the details of design and construction it gradually became practicable to use higher steam pressures and higher piston speeds, and consequently to obtain not only greater efficiency, but also a greater amount of power from engines of given bulk. The triple expansion engine, introduced by A. C. Kirk in 1874, did not come into general use until after 1881. It became the normal type of marine engine, with pressures ranging, as a rule, from 150 to 200 lb. per sq. inch, piston speeds generally of 500 or 600 ft. per minute, but sometimes as high as 900 or 1,000, and coal consumption of about 1½ lb. per hour per indicated horsepower. It continues to be very largely used in steamships which are not driven by turbines. In some instances quadruple expansion has been preferred, with somewhat higher pressures, but when the pressure is much raised the tendency is to abandon the piston type in favour of the steam turbine. This is true both in marine and in land practice. The gigantic concentration of steam power that is found in a great steamship or in a power station has been made practicable by the turbine. The selection of Parsons turbines in 1907 as the motive engines of the Cunarders "Lusitania" and "Mauretania" constituted a new departure in steam engineering. It was then a novelty to develop some 70,000 horsepower in the engine room of a single ship. Many of the turbines in power stations now exceed this figure.

Introduction of the Steam Turbine.—The invention of the steam turbine has revolutionized marine engine practice, in respect especially of the largest and fastest vessels. For the generation of electricity the turbine has a notable advantage in directly developing the high speed of rotation which a dynamo requires, and, when designed on a large scale, its efficiency is unrivalled by steam engines of other kinds. To Sir Charles Parsons we owe not only the main idea of the modern steam turbine, but also the invention of many mechanical features and details essential to its practical success and general adaptation.

In the steam turbine, as we have seen, pressure, instead of being exerted on a piston, is employed in the first instance to set the fluid itself in motion. There is a conversion of pressure-energy into velocity-energy as a preliminary step towards obtaining the effective work of the machine. If this were done in a single step it would involve immensely high velocities in the steam jet and in the vanes on which the jet acts. Attempts to design a steam turbine were made by numerous inventors, but fell short of practical success mainly because of the difficulty of arranging for high enough velocity in the working parts to utilize a reasonably large fraction of the kinetic energy of the steam. There was a further difficulty in getting the energy of the steam into a suitable kinetic form, namely, to get the stream of issuing particles to take a single direction, without undue dispersion, when steam was allowed to expand through an orifice from a chamber at high pressure into a space where the pressure was greatly less.

In 1889 Dr. Gustaf de Laval introduced a form of steam turbine in which both of these difficulties were, to a considerable degree, overcome, partly by the special form of the nozzle used to produce the steam jet and partly by features of design which allowed an exceptionally high speed to be reached in the wheel carrying the vanes against which the steam impinged.

Parsons attacked the problem at an earlier date and in a different way, by his invention of the "compound" turbine. He divided the whole expansion of the steam into a great number of successive and separate steps and thereby limited the velocity acquired at each step to such an extent as to make it comparatively easy to extract the greater part of the kinetic energy as work done upon the moving blades, without making the velocity of these blades inconveniently high. Moreover, in Parsons's compound turbine the range of pressure through which the steam expands in each separate step is too small to cause any difficulty in the formation of the jets. The guide blades, which form the jets, are distributed round the whole circumference of the revolving wheel, and all the revolving blades are consequently in action at once. The steam streams from end to end of the turbine through an annular space between a revolving drum and the casing which surrounds it. Parallel rings of fixed guide blades project inwards from the casing at suitable distances, and between these are rings of moving blades which project outwards from the drum and revolve with it. At each step in the expansion the steam streams through a ring of fixed guide blades, and the streams so formed impinge on the next ring of moving blades, and so on. The construction, which is of great simplicity, is described, along with others, in the article TURBINE: STEAM. It lends itself well to the generation of power on a large scale, especially where a fairly high speed of rotation is wanted.

Parsons introduced his compound steam turbine in 1884. For some years it was made in small sizes only, and the steam was discharged to the atmosphere without condensation. So long, however, as this was done the steam turbine was sacrificing one of its most important advantages, namely, its exceptional capacity for utilizing the energy of low-pressure steam down to the lowest vacuum obtainable in a condenser. In 1891 it was first fitted with a condenser, and it then began to be used in electric supply stations. The first application to marine propulsion was in the "Turbinia," in 1897. The success of this little experimental vessel of 100 tons, which, with its horse-power of 2,100, made what was then a record in speed for any ship, was soon followed by the application of the turbine to war-ships and other steamers. In merchant vessels its use was at first limited to those of the highest speed, for the turbine shaft was directly coupled to the shaft of the screw propeller; but in 1910 Parsons introduced a mechanical reducing gear between the two, which allowed the turbine shaft to run much faster than the propeller shaft, to the great advantage in efficiency of both turbine and propeller. Later he followed this up by a "double-reduction" gearing which admitted of a still greater difference in speed of rotation between the propeller and the turbine. In most ships the single reduction system is sufficient for the purpose: its introduction greatly extended the range within which the turbine could be advantageously substituted for the three-cylinder or four-cylinder compound engine of the piston type in ocean-going steamships.

Enough has been said to show that the invention of the steam turbine is by far the most important step in steam engineering since the time of Watt. It solved the problem of using steam efficiently in an engine without reciprocating parts.

Early Theory.—In the early development of the steam engine inventors had little in the way of theory to guide them. Watt had the advantage of a knowledge of Joseph Black's doctrine of latent heat; but there was no philosophy of the relation of work to heat until long after the inventions of Watt were complete. The theory of the steam engine as a heat engine may be said to date from 1824, when N. L. Sadi Carnot published his ***Réflexions sur la puissance motrice du feu***, a remarkable essay in which he showed that heat does work only by being let down from a higher to a lower temperature. But Carnot was not then aware that any of the heat disappears in the process, and it was not until the doctrine of the conservation of energy was established in 1843 by the experiments of James Prescott Joule that the theory of heat engines began a vigorous growth. From 1849 onwards the science of thermodynamics was developed with extraordinary rapidity by Rudolf Clausius, W. J. Macquorn Rankine and William Thomson (Lord Kelvin) and was applied, especially by Rankine, to prac-

tical problems in the use of steam. Rankine's *Manual of the Steam Engine,* published in 1859, was the first attempt at a systematic treatment of steam-engine theory. It involved the simplifying assumption that the cylinder and piston might be treated as behaving to the steam like non-conducting bodies, in other words, that the transfer of heat between the steam and the metal might generally be disregarded. One effect of this was to treat the volume of steam consumed per stroke as corresponding to the volume of the cylinder up to the point of cut-off. When steam enters the engine cylinder it finds the metal chilled by the previous exhaust, and a portion of it is at once condensed. This has the effect of increasing, often very largely, the volume of boiler steam required per stroke As expansion goes on, the water that was condensed during admission begins to be re-evaporated, and this action is often prolonged into the exhaust. It is now recognized that exchanges of heat between the steam and its metal envelope cannot be ignored. They cause the actual performance to fall short, in some cases very much short, of the ideal limit. They may be reduced by suitable design

ACTION OF RECIPROCATING ENGINES

Most, though not all, reciprocating engines are double-acting. that is to say, steam from the boiler is alternately admitted to each side of the piston. In each double stroke, or revolution, there are four events for each end of the cylinder:—(1) *Admission,* which begins by the opening of a steam-valve when the piston is at or very near the limit of its travel; (2) *Cut-off,* at which the steam-valve is closed and admission ceases This may take place early in the stroke The steam which is enclosed behind the piston then expands, with falling pressure, while the stroke continues, until (3) *Release* occurs; that is to say, an exhaust-valve opens, allowing the steam to escape from the cylinder. Its discharge generally continues for a large part of the back-stroke, until event (4), at which the exhaust-valve closes, and *Compression* begins: from there to the end of the back-stroke, the steam remaining in the cylinder is compressed into the clearance space behind the piston. This compression of the residue of steam, which is called cushioning, assists smoothness of working as the piston passes what is called the dead-point, at the limit of its stroke, and the cushioning effect is often augmented by giving the steam-valve what is called "lead,"—that is, causing it to open a little before the piston reaches the dead point

Distribution of the Steam: Indicator Diagram.—Together, these various events of the stroke constitute what is termed the distribution of the steam. They are conveniently exhibited by drawing an indicator diagram of the action, such as that illustrated in fig. 4 There, on a base *PQ* which represents the stroke, lines are drawn to show the continuous changes of pressure that go on within the cylinder during the whole action. Starting from the beginning of the stroke at *a*, for one side of the piston, steam is admitted up to the point *b* which shows the cut-off. At (or near) the end of the forward stroke, at *c*, the steam is allowed to escape Compression, in the return stroke, begins at *e*. From *b* to *c* the steam confined in the cylinder is expanding, with falling pressure, doing work on the piston The whole work done in the revolution, namely the integral of the force acting on the piston and the distance through which it moves, is represented by the enclosed area of the indicator diagram, *a b c d*

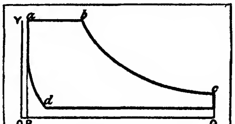


FIG 4—INDICATOR DIAGRAM SHOWING DISTRIBUTION OF STEAM

The diagram is idealised in the sense that the events are shown as if they happened suddenly, giving sharply defined changes from admission to expansion and so on In any real engine the events are necessarily gradual, for no valve—whatever its type—can close or open quite instantaneously A real indicator diagram accordingly has a smoother outline with rounded corners to mark the places of cut-off, release, compression and admission. In practice release always occurs before the piston has quite completed its stroke.

The distance *PQ* which represents the stroke may (by the use of an appropriate scale) be interpreted as a volume, namely the volume swept through by the piston, and a point *O* behind *P* may be so taken that *OP* represents, on the same scale, the volume of the clearance. The distance measured horizontally from the line *OY* to any point of the curve represents the whole volume of steam behind the piston at that point, and the curve between admission and release exhibits the relation of the pressure to the

total volume of the steam enclosed behind the piston throughout its process of expansion

Actual indicator diagrams may be automatically drawn by attaching to the cylinder of the engine a device in which a pencil is made to rise or fall proportionally to the variations of steam pressure, while a paper, on which it inscribes a record, moves back and forth horizontally through distances proportional to the movement of the engine piston Many forms of indicator have been designed to give, in some such way, a diagram in which the co-ordinates represent respectively the displacement of the piston and the pressure of the steam against it From such diagrams it is easy to infer the mean effective pressure throughout the stroke, and also to observe how the valves are working. By connecting the instrument successively to each of the two ends of the cylinder, in a double-acting engine, a complete record is obtained for the two strokes which make up a revolution. The "indicated horse-power" is determined by the formula

$$\text{I.H.P.} = \frac{nL(p_1A_1 + p_2A_2)}{33{,}000}$$

where A_1 and A_2 are the areas of the two sides of the piston, in square inches; p_1 and p_2 are the mean effective pressures on the two sides, in lb per sq. inch, as determined from the diagrams; n is the number of revolutions per minute, and L is the stroke in feet In trials of a steam engine such diagrams are taken during a considerable period. The amount and condition of the steam passing through the engine is observed, by measuring either the quantity of water discharged from the condenser (if of the surface type), or the quantity of feed-water required to be supplied to the boiler to keep the water level constant. From these data it becomes possible to compare the power developed with the heat supplied. Measurements of the heat rejected may also be made by observing the quantity of condensing water used and its rise in temperature; and together these figures give material for drawing up a balance sheet of the disposal of thermal energy.

The Slide-valve.—The admission and exhaust of steam, for each end of the cylinder, may be controlled by separate valves, but very commonly a single moving piece, called a slide-valve, serves to control the events for both ends. The slide-valve was invented by William Murdock, an assistant of Watt. A common form of it is illustrated in section in fig. 5, which also shows the cylinder, with the piston, and the steam ports and passages leading to each end of the cylinder. The face on which the valve slides is a plane surface on one side of the cylinder with three ports or openings which extend across the greater part of the cylinder's width. The central opening is the exhaust port, through which the steam escapes after doing its duty in the cylinder. The others, which are narrower, lead to the two ends. The valve itself is a box-shaped cover, sliding on the face, and contained in the valve-chest, or chamber to which steam is admitted from the boiler. When the valve moves a sufficient distance to either side of the middle position steam is admitted to one end of the cylinder, past the outer edge. Similarly steam escapes from the other end of the cylinder, through the cavity of the valve, to the exhaust port. The valve takes its motion from an eccentric on the engine shaft, which is set more than 90° ahead of the crank, so that the valve has already begun to uncover the port on one side when the piston is at the corresponding dead point, with the result that steam passes from the steam chest above the valve into the space behind the piston. Figure 6 shows a slide-valve in its middle position, and illustrates the internal lap *i* and the external lap *e* which the valve must have to make expansive working possible. At the beginning of the stroke it has already passed its middle position by an amount at least equal to *e*, so that steam may enter. It continues to move further, opening the port more widely, and then begins to return, while the piston is still advancing in the cylinder. At a particular point in its return the outer edge of the valve closes the port; this determines the instant of cut-off. The piston continues to advance, with expansion of the steam confined in the cylinder, while the valve continues to move back, until the inner edge of the valve begins to uncover the port, allowing steam from the cylinder to escape to the exhaust channel. This point, which depends on the internal lap *i*, determines the instant of release. The port then opens more widely to exhaust, and remains open during most of the back stroke of the piston, until the valve, again moving in the original direction, brings its inner edge again over the port and compression begins. Similar events for the other end of the cylinder are determined by the other side of the valve. The positions of the piston when the several events occur depend on the amounts of the laps *e* and *i*, and of the "angular advance" which is the excess over 90° in the angle by which the eccentric stands ahead of the crank. If there were no laps and no angular advance steam would be admitted during the whole forward stroke and exhausted during the whole backward stroke. By giving the valve laps and angular advance expansive working becomes possible. But the slide-valve is not well adapted to effect a cut-off early in the stroke, and when much expansion is desired, a device called a separate expansion valve is added, or valves of a different type are used to control the distribution of the steam.

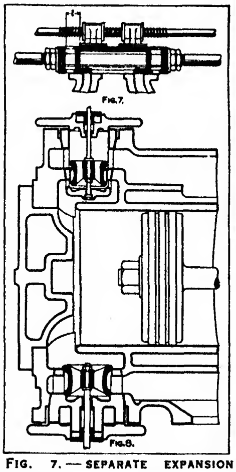

FIG. 7.—SEPARATE EXPANSION VALVE

FIG. 8.—CROSS SECTION OF ONE END OF A CYLINDER SHOWING DROP VALVES

Separate Expansion Valves.—Fig. 7 shows Meyer's expansion valve, which consists of two blocks sliding on the back of a slide-valve. It is caused to reciprocate by an eccentric, generally set directly opposite the crank, so that it moves to the left while the piston moves to the right, and *vice versa*. The admission of steam ceases when the relative displacement of the expansion blocks over the slide-valve amounts to the distance *l*, and this can be arranged to happen early in the piston's stroke without affecting the release or the compression.

In this example the rod which carries the two blocks is fitted with right- and left-handed screws, so that by turning the rod the distance between the blocks may be adjusted, and the distance *l* consequently altered. This allows the valve to be set to give an earlier or later cut-off: when *l* is increased by bringing the blocks nearer together, the cut-off comes later in the stroke. The adjustment may be made while the engine is running. Another way to change the cut-off with a valve of the Meyer type is to alter its travel. Increasing the travel of the expansion valve, while *l* remains constant, makes the cut-off come later.

In many engines the events are controlled by using, at each end of the cylinder, separate valves for admission and exhaust (fig. 8). Sometimes these are drop valves which are "double-beat" in the sense that the valve when it drops into its seat closes simultaneously two passages. These are so arranged that the steam pressure tending to close or open the valve remains balanced, and no large force has to be exerted. Such valves are often worked by cams and levers from a lay shaft alongside the cylinder, driven from the main shaft so as to turn in unison. In many examples the valves giving admission are caused to close by a tripping device; that is to say they spring suddenly into the closed position, at the instant when cut-off is desired, through the action of a trigger which brings a closing spring into play; and the tripping device is connected with the governor of the engine in such a manner that the cut-off comes earlier or later when the speed exceeds or falls short of the normal. In this way the engine automatically adjusts the amount of power it develops to suit changes in the demand made upon it by the mechanism which it drives.

Balanced Valves.—Fig. 5 shows a slide-valve form usual in locomotives and small engines but in large sizes the objection is that the unbalanced pressure of steam on the back of the valve would cause much friction and wear in the movement of the valve over the working face on which it slides. In large engines, such as those of steamships, it is usual to relieve the pressure of the valve on the working face by fitting the back of the valve with what is called a relief frame, extending between the valve and the steam-chest cover, the effect of which is to prevent the steam of the steam-chest from having access to the whole back surface of the valve. Another device, often resorted to, is to substitute for the flat form of slide-valve a piston form in which the effective sliding portions of the valve extend all round the surface of a cylinder and slide over cylindrical fixtures in the valve chest, round which the steam-ports extend.

Reversing Gears.—The slide-valve is a particularly convenient means of controlling the admission of steam when, as in locomotives or marine engines, etc., the engine's direction of motion has frequently to be reversed. It is only necessary to provide means by which the valve may be actuated by either of two eccentrics, one set at the angle suitable for forward running and the other set at the angle suitable for backward running.

In Stephenson's link motion which is an early and familiar device for this purpose, the engine shaft carries two eccentrics, one of which is set ahead of the crank at a suitable angle for one direction of running, and the other at a suitable angle for the other direction. Their rods are connected to the ends of a link which gives its name to the contrivance. The link is a slotted bar curved to a circular arc, and capable of being moved up or down, being suspended from a rod which can be raised or lowered by means of the hand lever above. The valve rod ends in a block which slides within the link. This device allows either the forward eccentric or the backward eccentric to determine the motion of the valve, and so allows the engine to be reversed. But it does more, for if the link be set to an intermediate position, in which it takes its motion chiefly from one eccentric but partly from the other, the valve receives a motion virtually the same as that which it would get from a single eccentric of shorter travel and greater

angular advance. The effect is to give a distribution of steam in which the cut-off is hastened and the expansion and compression are increased. Thus besides allowing of "full forward" and "full backward gear" the link may be "notched up" to give a much shorter admission of steam along with more compression, a matter of practical value in the running of a locomotive, where frequent large variations in the demand for driving effort have to be met.

Various other forms of link-motion have been devised which

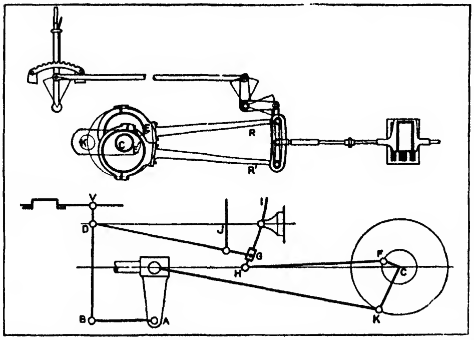

FIG 9—(ABOVE) STEPHENSON'S LINK-MOTION. (E, E') ECCENTRICS. (R, R') RODS CONNECTED TO ECCENTRICS. (BELOW) WALSCHAERT'S GEAR

share this advantage It is also shared by a group of equivalent mechanical devices, called by the general name of "radial valve gears," in which only one eccentric is employed but the valve is caused to take a motion capable of being varied in the same way. Of these the most widely used is the Walschaert's gear, very common in locomotives, a skeleton diagram of which is shown in fig. 9. There *A* is a projection moving with the engine piston. The valve *V* takes motion partly from it, through the rods *AB* and *BV;* but *BV* has a fulcrum at *D,* the position of which varies through the movement of the rod *DG* That rod is supported by a suspension rod *J,* and its end at *G* can slide in a link *HI* rocking about a fixed fulcrum at *O* There is one eccentric, *CF,* set at right angles to the crank *CK,* and giving motion to the rocking link *HI* by the rod *FH.* The block *G* can be shifted from near *H* to *I* by raising the suspension rod *J.* This reverses the motion, and allows also of notching up to any intermediate position.

Governing.—To keep a steam engine running at a uniform speed, notwithstanding variations in the demand for power, hand regulation may to some extent serve, but in very many cases an automatic regulator called a governor is provided. Regulation, whether by hand or by automatic governor, may be effected in two ways: the steam may be throttled more or less on its way from the boiler to the engine, so that the pressure of admission is reduced when the speed tends to rise, and increased when the speed tends to fall: or the point of cut-off may be varied, with the result of admitting a greater or less volume of steam in each stroke. In small engines the governor often acts on a throttle valve, but at engines which aim at efficiency it is preferable to govern by altering the cut-off. In such engines, to secure in any case a proper amount of expansion, there is an early cut-off, and a small change in its position largely affects the amount of steam admitted and consequently the amount of work done

Watt's original governor was a pair of balls revolving about a vertical spindle as conical pendulums under the combined effect of their own weight and the "centrifugal force" due to their speed of revolution. Any increase of speed sufficient to overcome the slight friction of the attached gearing made them take up a higher position, and in so doing they partially closed a throttle valve. This went on till, at a slightly greater speed than before, equilibrium was established between the supply of steam and the demand for power. Here, as in all governors, the effect is not to maintain a strictly constant speed, but to prevent the variation, either way, from exceeding narrow limits.

In modern governors the "centrifugal force" of the balls generally acts not simply against their own weight, but against an extra load or against the force of a spring.

In many factory and other engines the governor determines the position of cut-off by means of a trigger action of the type already mentioned: the admission valve, which has been opened and held open by a cam turning with the engine shaft, is suddenly disconnected by the release of a trigger, at a point depending on the exact height of the governor balls.

Function of the Fly Wheel.—The function of the governor is, generally, to keep the engine running at a nearly uniform rate, measured in turns per minute: the function of the flywheel is to keep the rate nearly uniform within the limits of any one revolution For this purpose it must act as a reservoir of energy, alternately storing and restoring the excess amounts which result from periodic variations of turning moment in the operation of the piston on the crank. At the dead points the piston's rate of doing work is zero, and it rises to a maximum at an intermediate point the position of which may be much affected by an early cut-off. The flywheel is drawn upon for energy during those parts of the revolution in which the work done by the piston (or pistons) on the engine shaft is less than the work done by the shaft on the mechanism which the engine drives; and it takes up the surplus during the other parts of the revolution. To effect this alternate give and take of energy the flywheel must undergo small variations of speed, the magnitude of which may be kept down to any assigned amount by giving the rim a sufficient mass and speed.

Inertia of Reciprocating Parts.—The effective effort on the crank is greatly influenced, especially in high-speed engines, by the inertia of the piston, piston-rod and connecting rod. At the beginning of the stroke, when the piston is coming towards the crank-shaft, these reciprocating masses are acquiring motion, from a point near the middle to the end of the stroke they are losing motion Hence in the early part the effort on the crank is reduced below what is due to the steam-pressure on the piston and in the later part it is increased In a high-speed engine the forces due to acceleration become so large as seriously to affect questions of design In direct-acting steam pumps the inertia of pump rods and buckets forms an additional item in the consideration of reciprocating mass: its effect there is on the whole beneficial in tending to equalize the force which is exerted on the pump throughout the stroke.

Balancing of Engines.—Another aspect of the acceleration of reciprocating parts is its effect on the balance of the engine as a whole. This is specially important in locomotives and marine engines (*q v.*). In a locomotive the forces on the engine frame arising from the inertia of the pistons and rods tend to make the engine sway laterally: this is to some extent prevented by placing "balance masses" on the wheels But such masses, although they may be adjusted nearly to balance the horizontal forces, introduce unbalanced vertical forces, causing what is called hammerblow In extreme cases these vertical forces might even lift the wheels from the rails: short of that, however, they are objectionable in causing periodic variations in the pressure on the rails, which tend to set bridges into oscillation and may add substantially to the stresses for which the railway engineer must provide.

TYPES OF RECIPROCATING ENGINES

In classifying engines with regard to their general arrangement of parts and mode of working, account has to be taken of a considerable number of independent characteristics. We have first a general division into *condensing* and *non-condensing* engines, with a subdivision of the condensing class into those which act by surface condensation and those which use injection. Next there is the division into *compound* and *non-compound,* with a further classification of the former as double-, triple-, or quadruple-expansion engines Again, engines may be classed as *single* or *double-acting,* according as the steam acts on one or alternately on both sides of the piston. Again, a few engines—such as steam hammers and certain kinds of steam pumps—are *non-rotative,* that is to say, the reciprocating motion of the piston does work simply on a reciprocating piece; but generally an engine does work on a continuously revolving shaft In most cases the crank-pin of the

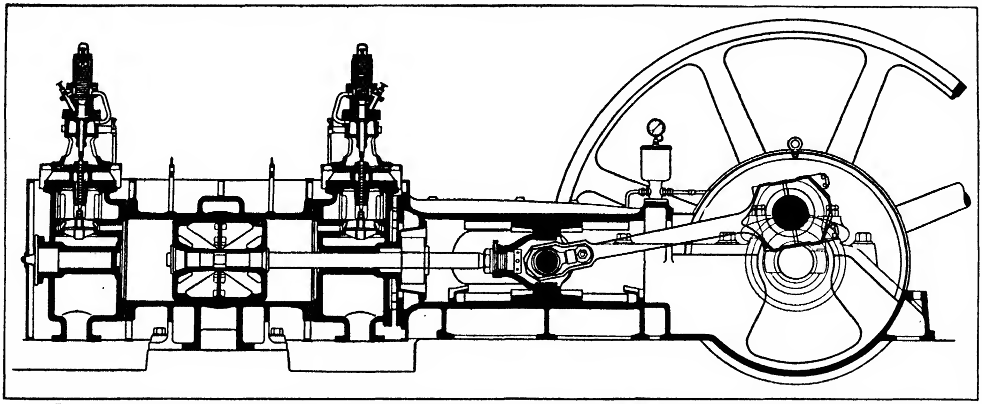

FIG. 10.—UNIFLOW ENGINE IN WHICH THE PISTON ACTS AS EXHAUST VALVE AND THE ADMISSION VALVES ARE IN THE CYLINDER ENDS

revolving shaft is connected directly with the piston-rod by a connecting-rod, and the engine is then said to be *direct-acting;* in other cases, of which the beam engine is an historical example, a lever is interposed between the piston and the connecting-rod. The same distinction applies to non-rotative pumping engines, in some of which the piston acts directly on the pump-rod, while in others it acts through a beam. The position of the cylinder is another element of classification, giving *horizontal, vertical* and *inclined cylinder* engines. In most vertical engines the cylinder is above the connecting-rod and crank. In *oscillating cylinder* engines (a type still found in some river boats) the connecting-rod is dispensed with; the piston-rod works on the crank-pin, and the cylinder oscillates on trunnions to allow the piston-rod to follow the crank-pin round its circular path. In *rotary* engines there is no piston in the ordinary sense; the steam does work on a revolving piece, and the necessity is thus avoided of afterwards converting reciprocating into rotary motion.

Beam Engines.—In the single-acting atmospheric engine of Newcomen the beam was a necessary feature; the use of water-packing for the piston required that the piston should move down in the working stroke, and a beam was needed to let the counterpoise pull the piston up. Watt's improvements made the beam no longer necessary; and in one of the forms he designed it was discarded—namely, in the form of pumping engine known as the Bull engine, in which a vertical inverted cylinder stands over and acts directly on the pump-rod. However, the beam formed a convenient driver for pump-rods and valve-rods; and the parallel motion invented by Watt as a means of guiding the piston-rod, which could easily be applied to a beam engine, was, in the early days of engine-building, an easier thing to construct than the plane surfaces which are the natural guides of the piston-rod in a direct-acting engine. In modern practice the direct-acting type has almost wholly displaced the beam engine.

Direct-acting Engines.—Of direct-acting engines the horizontal arrangement has in general the advantage of greater accessibility, but the vertical economises floor space. In small forms the engine is generally self-contained, that is to say, a single frame or bedplate carries all the parts including the main bearings in which the crank-shaft with its flywheel turns. The frame often takes what is called a girder shape, which brings a portion of it into a favourable position for taking the thrust between the cylinder and the crank-shaft bearings and allows two surfaces to be formed on the frame to serve as guides for the cross-head. When a condenser is used with a horizontal engine it is often placed behind the cylinder, and the air-pump, which may be within the condenser, has a horizontal plunger or piston on a "tail-rod" or continuation of the main piston-rod through the back cover of the cylinder. In large horizontal engines the condenser generally is in a well below, and its pump is driven by a mechanism linked with the crosshead.

Coupled Engines.—When uniformity of driving effort or the absence of dead points is important, two independent cylinders often work on the same shaft by cranks at right angles to each other. Such engines, which are called "coupled," can start readily from any position; the ordinary locomotive engine is an example. In some engines three cylinders, set to work on cranks 120° apart, co-operate in giving a still more uniform drive. Winding engines for mines and collieries, in which ease of starting, stopping and reversing is essential, are very generally made by coupling a pair of cylinders on opposite sides of the winding drum.

Compound Engines, Coupled or Tandem.—Large direct-acting engines are usually compounded either by having a high- and a low-pressure cylinder side by side, with cranks at right angles, or by putting one cylinder behind the other with a common centre line. The latter is called a *tandem* arrangement. In a tandem engine, since the pistons agree in phase, the steam may expand directly from the small into the large cylinder. But the connecting-pipe and steam chest form a receiver of considerable size, and it is preferable to cut off the supply of steam to the large cylinder at an earlier stage of the stroke. For mill engines the compound tandem and compound coupled types of engine are very usual. The high-pressure cylinder is often fitted with some form of trip-gear.

The chief advantage of compounding, as was pointed out in the historical section, is that it reduces the condensation which hot steam undergoes in the cylinder through contact with metal which has been chilled by the exhaust of the previous stroke. Compound working acts beneficially by narrowing the range through which the temperature periodically fluctuates in the metallic surfaces exposed to contact with the operative steam. The amount of steam that is at once condensed on admission depends on the extent to which the surface with which it comes in contact has been chilled during the previous exhaust. For this reason there is less loss through initial condensation in a compound engine giving the same total ratio of expansion.

Uniflow Engine.—The periodic give and take of heat between the steam and the metallic surfaces, which is a serious source of loss in any reciprocating engine, can be reduced by having separate valves for admission and exhaust, so that the same port-surfaces and valve-surfaces are not brought into contact with hot and comparatively cold steam. This idea is carried further in what is called the "uniflow" engine, by an ingenious arrangement which secures that the ends of the cylinder, where the steam is admitted, shall always be kept hot, the exhaust taking place at the middle of the cylinder through ports in the circumference which are uncovered by the motion of the piston.

The uniflow design is a recent but conspicuously successful departure from earlier practice. It allows high pressure steam to be expanded in a single cylinder without the drawbacks ordinarily

entailed in non-compound working There is, however, still enough exchange of heat between the metal and the steam to make superheating highly advantageous

Condensation.—In land engines a jet form of condenser is common, but surface condensation is resorted to when the available water-supply is unsuited for boiler feed. When there is no large supply of condensing water a very fair vacuum can be obtained by using an *evaporative condenser,* consisting of a stack of pipes into which the exhaust steam is admitted and over which a small amount of cooling water is allowed to drip. This water is evaporated by the heat which the condensing steam gives up. Such a condenser is placed in the open, generally on a roof where the air has free access The amount of water it uses need not exceed the amount of steam that is condensed, and is a small fraction of the amount that would be required in a jet or surface condenser

High-speed Direct-acting Engines.—Prior to the development of the steam turbine the demand for engines suitable for driving electric generators without the intervention of a belt led to the introduction of various forms of direct-acting engine adapted to run at a high speed. Some of these were *single-acting,* steam being admitted to one side of the piston only, generally the back, with the result that the rods could be kept in a state of thrust throughout the revolution, and alternations of stress in them and at the joints thereby avoided, together with the knocking and wear of the bearing brasses which it is apt to cause. To secure, however, that the connecting-rod should always push and never pull against the crank-pin there had to be much cushioning during the out stroke on account of the fact that from about the middle of that stroke to the end the reciprocating mass was being retarded. In engines of this class designed by P. W. Willans, which were at one time much used, but are now displaced by turbines, the cushioning was provided by means of a supplementary piston which compressed air during the out stroke, the energy which the reciprocating masses had to part with in losing their motion during the second half of the out stroke was stored in this air and was restored in the succeeding down stroke. The engine was entirely enclosed in a casing the bottom of which formed an oil bath in which the cranks splashed to ensure ample lubrication. This feature is retained in many modern high-speed engines.

Pumping Engines.—In engines for pumping or for blowing air it is not essential to drive a revolving shaft, and in many forms the reciprocating motion of the steam piston is applied directly to produce the reciprocating motion of the pump-piston or plunger. Often an inverted vertical triple expansion engine is used, resembling the usual marine form, with a pump-plunger under each of the three cylinders. Most of the power is directly transmitted from the piston to the pump, but there is an auxiliary crank for each cylinder, driving a shaft with a flywheel to equalize the effort on the pump.

A familiar example of direct-acting pump is the small donkey pump used for feeding boilers, in which the steam-piston and pump-plunger are on one and the same rod. In some of these pumps a rotative element is introduced, partly to secure steadiness of running and partly for convenience in working the valves. But many pumps of this class are entirely non-rotative, and in such cases the steam is generally admitted throughout the stroke without expansion The valve may be actuated by tappets from the piston-rod. In some cases a tappet worked by the piston as it reaches each end of its stroke throws over an auxiliary steam-valve, which admits steam to one or other side of an auxiliary piston carrying the main slide-valve.

Pulsometer.—Hall's "pulsometer" is a peculiar pumping engine without cylinder or piston, which may be regarded as the modern representative of the engine of Savery. The sectional view, fig. 11, shows its principal parts There are two chambers, *A, A′,* narrowing towards the top, where the steam-pipe *B* enters. A ball-valve *C* allows steam to pass into one of the chambers and closes the other. Steam entering (say) the right-hand chamber forces water out of it past the clack-valve *V* into a delivery passage *D,* which is connected with an air-vessel. When the water level in *A* sinks so far that steam begins to blow through the delivery passage, the water and steam are disturbed and so brought into intimate contact, the steam in *A* condenses, and a partial vacuum is formed This causes the ball-valve *C* to rock over and close the top of *A,* while water rises from the suction-pipe *E* to fill that chamber. At the same time steam begins to enter the other chamber *A′,* discharging water from it, and the same series of actions is repeated in each chamber alternately. While the water is being driven out there is comparatively little condensation of steam, partly because the shape of the vessel does not promote the formation of eddies, and partly because there is a cushion of air between the steam and the water. Near the top of each chamber is a small air-valve opening inwards, which allows a little air to enter each time a vacuum is formed. When any steam is condensed, the air mixed with it remains on the cold surface and forms a non-conducting layer. The pulsometer is, of course, far from efficient as a thermodynamic engine, but its adaptability to situations where other steam-pumps cannot easily be applied, and the simplicity of its working parts, sometimes make it practically useful.

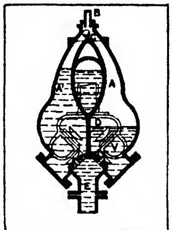

FIG. 11—HALL'S PULSOMETER

Marine Engines.—The early steamers were fitted with paddle-wheels, and the engines used to drive them were for the most part modified beam engines. Bell's "Comet" was driven by a species of inverted beam engine, and another form of inverted beam, known as the *side-lever* engine, was for long a favourite with marine engineers. An old form of direct-acting paddle-engine was the *steeple* engine, in which the cylinder was set vertically below the crank. Two piston-rods projected through the top of the cylinder, one on each side of the shaft and of the crank They were united by a cross-head sliding in vertical guides, and from this a return-connecting-rod led to the crank Most modern paddle-wheel engines are direct-acting engines of the ordinary connecting-rod type, with the cylinders fixed on an inclined bed and the guides sloping up towards the shaft

When the screw-propeller began to take the place of paddle-wheels in ocean steamers, the increased speed which it required was at first obtained by using spur-wheel gearing in conjunction with one of the forms of engines then usual in paddle steamers. Types of engine better suited to the screw were introduced later, and were driven fast enough to be connected directly to the screw-shaft. After passing through various forms, now obsolete, the marine engine settled into one which is now universal in all screw steamships that are not driven by steam turbine

This is the inverted vertical direct-acting engine, with two or more cylinders placed side by side directly over the shaft. It has the great advantage that the shaft can readily be put at the low level necessary for screw propulsion. Two, three and four cranks are employed, the arrangement with four cranks being specially suitable, as has already been pointed out, when a balance of the engine at high speeds has to be secured. In vessels of high speed and power the engines are often arranged in twin sets, on two shafts with twin screw propellers.

The marine engine is always furnished with a surface condenser, consisting of a multitude of brass tubes about $\frac{3}{4}$ inch in diameter cooled by sea-water which is caused to circulate through the condenser by means of a circulating pump. This pump and the air pump are often driven independently of the main engine.

It is in marine practice that the most powerful reciprocating engines are still to be found, although in the largest and fastest vessels the turbine has taken their place. Another and more recent rival is the internal combustion engine, using the Diesel cycle of action, which by 1928 had found favour in many new liners The reciprocating engine continues, however, to be much used for sea-going vessels, especially those of the "tramp" class, most commonly in the triple expansion form. Often the third stage of the expansion is performed in two cylinders, making four in all. This avoids the use of a very large cylinder, and secures an advantage in the better balance which can be obtained with four cranks.

Locomotive Engines.—The ordinary locomotive consists of a

pair of direct-acting horizontal or nearly horizontal engines, fixed in a rigid frame under the front end of the boiler, and coupled to the same shaft by cranks at right angles, each with a single slide-valve worked by a link-motion, or by a form of radial gear. The engine is non-condensing, except in a very few special cases, and the exhaust steam, delivered at the base of the funnel through a blast-pipe, serves to produce a draught of air through the furnace. In some instances a portion of the exhaust steam, amounting to about one-fifth of the whole, is diverted to heat the feed-water.

On the shaft are a pair of driving-wheels, whose frictional adhesion to the rails furnishes the necessary tractive force. Nearly always a greater tractive force is secured by having two or more driving-wheels on each side, connected by a coupling-rod between pins on the outside of the wheels.

It is general to have under the front of the engine a group of smaller wheels which do not form part of the driving system. These are carried in a *bogie,* that is, a small truck upon which the front end of the boiler rests by a swivel-pin or plate which allows the bogie to turn, so as to adapt itself to curves in the line, and thus obviate the grinding of tyres and danger of derailment which would be caused by using a long rigid wheel base.

In *inside-cylinder* engines the cylinders are placed side by side within the frame of the engine, and their connecting-rods work on cranks in the driving shaft. In *outside-cylinder* engines the cylinders are spread apart far enough to lie outside the frame of the engine, and work on crank-pins on the outsides of the driving wheels. Many modern locomotives combine the outside and inside arrangement, in order to get greater power, placing one or in some cases two cylinders within the frame, as well as two outside.

The principle of compounding has often been applied to locomotive engines, but without much advantage. (*See* LOCOMOTIVES.)

THEORY OF THE STEAM ENGINE AS A HEAT ENGINE

Properties of Steam.—Steam-engine theory is an application of the principles of thermodynamics (*q.v.*) to a machine using steam as its working substance. The relevant properties of the substance have been briefly described in the article STEAM. They include the pressure, temperature, and density (or volume per unit of mass); also (per unit of mass) the entropy ϕ and the total heat I. For definitions of these quantities reference should be made to that article. Numerical values will be found in Callendar's or other steam tables, over a sufficiently wide range of conditions to meet the purposes of the engineer.

Given steam in any initial state, we have to consider what happens when it expands, doing work, as in the cylinder of a steam engine. It is easy to imagine steam expanding without turbulence in an ideal cylinder which is a perfect non-conductor of heat. Under these conditions no heat is being taken in, and there is no change of entropy: such expansion is said to be *adiabatic.* Adiabatic expansion, and adiabatic compression, although never strictly realized owing to the influence of the conducting cylinder walls, are ideal actions important in the theory of the steam engine.

During adiabatic expansion the substance is doing work at the expense of its stock of internal energy, and its temperature falls. Steam expanding adiabatically becomes partly condensed: the substance then becomes a mixture of saturated steam with water at the same temperature, and the energy or the total heat of one pound is to be found by considering what fraction is present as water and what fraction is steam. Such a mixture is often called wet steam. The degree of wetness reached at any stage of adiabatic expansion is readily calculated by taking account of the fact that the expanding mixture keeps its entropy unchanged.

From the general principles of thermodynamics it is easy to assign an upper limit to the efficiency of a steam engine, when the temperatures are known at which the working substance takes in and rejects heat. By "efficiency" is here meant the ratio of the work done to the quantity of heat supplied. Suppose, to simplify the problem, that there is no superheating, that is to say no supplementary taking in of heat after the steam has been formed at the constant temperature T_1 of the boiler. Suppose also that the only rejection of heat is at the constant temperature T_2 of the condenser. Then the principle of Carnot (*see* THERMODYNAMICS) shows that under ideally favourable conditions of working the fraction of the heat supplied which is converted into work cannot exceed $1-T_2/T_1$, when the temperatures are expressed on the absolute scale.

Carnot Cycle.—This result would be attained in an engine working in a strictly reversible manner, where the whole change from T_1 to T_2 occurs as a result of adiabatic expansion, and the whole change from T_2 to T_1 as a result of adiabatic compression. The indicator diagram of an ideal engine working in this manner is shown in fig. 12. The engine there imagined is one whose cylinder also serves as boiler and condenser. It is supposed to have perfectly non-conducting sides, but a conducting bottom to which any one of three bodies A, B, or C may be applied. B is a non-conducting cover, to be applied during the two adiabatic stages. A is a hot "source," maintained at a high temperature T_1, and C is a cold "sink" or receiver of heat, maintained at a low temperature T_2. Imagine the cylinder to contain one lb. of water at T_1 and A to be applied, while the piston begins to move towards the right. The "isothermal" (constant temperature) line *ab* is traced out during the evaporation of the water. At *b* the substance is all steam. A is then removed, B is applied, and the adiabatic expansion *bc* takes place, until the temperature of the working substance falls to T_2. C is then applied and the piston is pressed back, giving an isothermal line *cd* during which most of the steam is condensed. At *d* there is a mixture, chiefly water, which is adiabatically compressed. If this point *d* has been properly chosen, the operation *da* completes the cycle, bringing the substance back to the condition *a* in which it is all water at temperature T_1. The whole process is called Carnot's cycle.

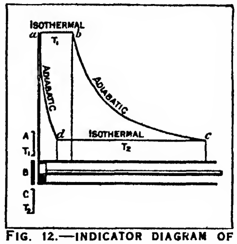

FIG. 12.—INDICATOR DIAGRAM OF CARNOT'S CYCLE

The formula $1-T_2/T_1$ which expresses the efficiency in this ideal operation shows the importance of making T_1 high and T_2 low. No real engine attains this limit of efficiency, for no engine completely expands the steam down to the condenser temperature in a strictly adiabatic manner. Further, no engine has an adiabatic compression stage corresponding to *da*: the use of a separate condenser makes that impracticable.

The action in an engine cylinder may be more appropriately idealized as in fig. 13 where *AB* represents the admission of the steam at T_1, *BC* its adiabatic and complete expansion to T_2, and *CD* its rejection to the condenser. Under these conditions it is easy to show that the work done, which corresponds to the area of this ideal diagram, is equal to

$$I_1-I_2$$

for each lb. of steam admitted to the engine, where I_1 is the total heat (per lb.) on admission, and I_2 is the total heat (per lb. of mixture) in the condition *C*, when expansion is complete. This applies whatever be the state of the steam on admission, whether superheated or not. The quantity I_1-I_2 is called the *adiabatic heat-drop,* and measures the greatest amount of work theoretically obtainable from each lb. of steam. In practice about 70 per cent. of the adiabatic heat-drop may be realized in favourable cases. Tables of the adiabatic heat-drop, for steam in various assumed initial states as to pressure and temperature, expanding to various assumed condenser pressures, have been compiled, and are of great service in problems of engine design.

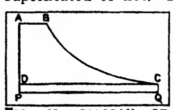

FIG. 13.—DIAGRAM OF THE ACTION OF AN AVERAGE ENGINE

Rankine Cycle.—The process exhibited in fig. 13 becomes a complete cycle when, in addition, account is taken of the action by which the feed-pump restores the condensed steam to the boiler. Thus completed the process is called the Rankine cycle. Its efficiency is necessarily somewhat less than that of the Carnot cycle of fig. 12. Superheating, which is not in practice carried

beyond a temperature of 400° C, and rarely so far, adds to the heat-drop by increasing I_1. But its chief effect on the efficiency of the process is indirect. By tending to keep the steam in a drier state it greatly reduces the losses that arise through exchange of heat between the working substances and the cylinder walls. in effect superheating makes the expansion more nearly adiabatic than it would otherwise be, and therefore gives a better approach to the ideal conditions of fig. 12. In a turbine superheating is beneficial by reducing the friction of wet steam on the blades.

Entropy-temperature Diagrams.—In exhibiting graphically the action of an engine under assumed conditions of working we may adopt various alternatives to the pressure-volume or "indicator" diagram One interesting form takes for its two co-ordinates the temperature and the entropy: another (introduced by Mollier) takes the entropy and the total heat Both of these diagrams are instructive in allowing the action to be traced through its several stages and in exhibiting the differences which result from varying the conditions of supply and of condensation They show the direct influence of superheating, and the amount of wetness to be expected at any stage in the expansion. They allow, in some cases, measurement from a chart to take the place of numerical calculation; but their greatest merit is that they enable the operation of the working fluid to be visualized. No account of such diagrams can, however, be attempted within the limits of this article.

Modern High-efficiency Steam Plants.—In modern steam engines, especially of the turbine class where a very large range of expansion may be effectively carried out, efficiency is aimed at by using the best possible vacuum, to make T_2 low, and by raising the pressure of supply to make T_1 high Pressures approaching 1000 lb per square inch are not uncommon, occasionally that figure is exceeded, and even at the highest pressures some additional high-temperature heat is taken in by superheating Reheating at one or more stages during expansion is resorted to, in order to prevent the expanding steam from becoming unduly wet. Another device, which is also applied in the most economical large-scale turbine plants, is to remove a portion of the expanding steam at each of two or three stages, and apply it in heating the feedwater on its way back from the condenser to the boiler This progressive heating of the feedwater, by "bleeding" the turbine of steam which has already done more or less work, is called "cascade" feed-heating Its effect is to make the whole cycle approach more nearly to the ideal cycle of Carnot, for the progressive feed-heating is nearly reversible and serves as a substitute, in this respect, for the adiabatic compression which makes that cycle differ from the cycle of Rankine (*See* also TURBINE. STEAM; LOCOMOTIVE, MARINE ENGINEERING.)

STEAM-GAUGE is an instrument which by utilizing the elasticity of a metal indicates the pressure of steam in a boiler or other vessel The action is explained in the article PRESSURE-GAUGE. The gauge must be fixed above the highest water level of the boiler, and stand away from it to avoid heating A gauge is unduly hot if it cannot be touched by the hand without discomfort, and the U-tube or syphon is therefore used for connection to the boiler. In order to avoid straining the action, a gauge is generally graduated to twice the working pressure Then the pointer stands vertically at the normal working pressure. High-pressure steam-gauges are those graduated for pressures between 200 lb. and 1,000 lb.

STEAM GENERATION. In a modern plant the course of operation can be traced broadly as follows: The water operates in a closed system and circulates in the form of steam or vapour and returns to its original state in the form of condensation. The water is first heated in feed water heaters, then goes through the tubes in the boilers and is changed to steam, then through a superheater that adds heat to it and from there to the utilizing equipment, a turbine for example. Finally it reaches the condenser from which it is returned to the starting point. The fuel usually starts through some preparation process such as crushing From there it is usually conveyed to bunkers that provide a continuous feed to the stokers under the boilers. It is burnt on the stoker grates in the furnaces with natural or forced draft and the gases are used as they leave the boiler in superheaters, economizers and air preheaters From there they finally escape through the stack. The economizers, superheaters and air preheaters are means by which some of the waste heat in the gases is reclaimed In steam generating plants is found all or some of this equipment and much other auxiliary equipment.

Subjects dealing with the generation of steam and with the equipment used in that process will be found in the articles: BOILERS; STEAM; COMBUSTION; ECONOMIZERS; ELECTRICAL POWER GENERATION; FUEL; HEAT; HEATING AND VENTILATION; PULVERIZED FUEL, STEAM ACCUMULATORS; STEAM CHEST, STEAM ENGINES; STEAM TURBINES, etc The present article attempts to co-ordinate the above references under the following headings: *Fuel; Combustion; Boilers; Mechanical Stokers; Other Equipment;* and *Selection of Steam Generating Equipment*

DEVELOPMENT OF STEAM GENERATORS

When steam units were first used industrially the boiler was purchased, a brickmason employed to set the boiler in place and a labourer indiscriminately secured to shovel fuel under the boiler to generate enough steam for the process in question. Fuel, labour and material were cheap It was not then economical to seek refinements in equipment or labour-saving devices, steam demands and pressures were low and in many cases, return tubular boilers answered the necessary requirements The industrial development of the 20th century caused rapidly increasing demands for power. These were first met by the improvement in the design of steam turbines, and the application of mechanical stokers to the existing boilers This met the needs for a few years but about 1916 steam turbine units began to increase rapidly in size and in 1929 single turbines of 60,000 kw were in operation and compound units of 200,000 kw turbines in course of construction In 1929 power houses containing 200,000 kw were in operation and power houses designed for 1,000,000 kw output were in process of erection In 1920 there were a few stations operating above 250 lb. pressure In 1929 there were several score of stations operating at over 500 lb pressure and others in course of erection

With these changes steam boilermakers discarded rule of thumb methods and employed research engineers, metallurgists and various specialists, installed machine tools, and adopted scientific methods of manufacture It was found at this time that the kind of water introduced into the boiler was of considerable importance; that the superheater should be located in a position that would give a wide range of load with very little change of temperature; that an evaporation of from 13 to 21 lb of steam per square foot of heating surface per hour should be the minimum, that the use of pulverized coal to secure these high ratings was desirable. Air-cooled refractory furnaces to burn pulverized coal at high ratings were tried but it was seen that, with water-cooled furnaces, a unit could be designed that would combine economy and efficiency with low maintenance cost and maximum continuous hours of service. With new and larger plants, the question of the best cycle to be used became of paramount importance affecting the boiler, superheater, feed water heater and economizer design. Means were needed to remove free oxygen from water to prevent corrosion The water entering the economizer was of higher temperature than when exhaust steam alone was used and the temperature of the gases leaving the economizer were too high for the best efficiency. Consequently air preheaters were developed to recover heat from the escaping gases, to provide hot air for drying the coal in the course of pulverization and to preheat the air for combustion before being introduced into the furnace. This cut down the time required for complete com-

bustion and raised the temperature of the furnace.

A 200,000 kw. plant will burn 100 tons of coal per hour and roughly one-tenth of this will be ash which must be removed. Methods of handling such quantities of materials, to provide for continuous and uninterrupted service, needed to be designed and installed. Safety consideration, abatement of smoke and noise, consideration of the design of the plant to fit in with surrounding buildings and landscape, were additional problems to be solved. It will be seen then that the problem of generation of steam to meet the requirements of modern industrial civilization has become extremely complex. (J. B. C.)

FUELS

The principal fuels for the generation of steam are coal and oil and these are treated under the articles: FUELS; PULVERIZED FUEL; PETROLEUM; COAL AND COAL MINING. There are, however, many localities where there is a limited supply of certain other materials which are sometimes used for fuel. *Coke breeze* is the small size coke and dust which is burned successfully on chain grate stokers. *Lignites* (*q.v.*) are burned on chain grate stokers and in pulverized form. *Wood* is usually put through a hogger to reduce it to small sizes for greater ease in handling and better burning in the furnace. The furnace must be large to provide sufficient time for complete combustion. *Bagasse* is the residual sugar cane, left after the juice has been extracted. The furnace is especially constructed for admitting air around its sides. The silica in the bagasse runs on to the grate and prevents air coming in from underneath. *Bonecoal* is the name given to coal taken off the top of coal seams and contains a large amount of impurities. Formerly discarded, it is now being burned on stokers and in pulverized form. *Anthracite coal* is used for household use in the districts adjacent to the anthracite fields. There is, however, a large amount of small sizes and dust that is now being burnt on travelling grate stokers, especially built for this purpose. *Natural gas* (*q.v.*), *blast furnace gas* (*q.v.*), *coke oven gas* (*q.v.*) and *producer gas* (*q.v.*) are also frequent boiler fuels.

Boilers are used to generate steam from the otherwise waste heat of cement kilns, metallurgical furnaces, coke ovens, gas generators and other such processes where high exit temperatures of the products of combustion prevail. In the McEwen-Runge process of coal carbonization, the coke in pulverized form serves as a fuel for boilers as does also the screened coke residue from the K.S.G. process which is burnt on forced draft chain grate stokers.

COMBUSTION

Combustion within the furnace of a steam generator consists in the chemical combination of the elements of the fuel with oxygen from atmospheric air supplied for that purpose. Corresponding to the weights of carbon (C), hydrogen (H), oxygen (O) and sulphur (S) in the fuel fired, the weight of air theoretically required for combustion is given by

$$A = \frac{2{\cdot}67\,C + 8\,(H - O/8) + S}{0{\cdot}232}$$

since atmospheric air contains 23·2% of oxygen by weight.

It is necessary to supply "excess air" above this theoretical minimum, however, and "free oxygen" always occurs in the products of combustion. Even with excess air, some combustible will escape unburnt from the furnace and a small amount of carbon monoxide may simultaneously be found in the products of combustion. The unburnt combustible is generally carbon with a corresponding combustion loss of 14,600 B.T.U. per pound. The formation of carbon monoxide (CO) instead of carbon dioxide (CO_2) is named "incomplete combustion." One pound of carbon burned completely to CO_2 liberates 14,600 B.T.U. One pound of carbon burned incompletely to CO liberates only 4,400 B.T.U., hence the loss is the difference between these values or 10,160 B.T.U. per pound of carbon burnt to carbon monoxide. While these losses are reduced by increasing the percentage of excess air, the gain in combustion efficiency is more or less counteracted by the increase in another loss, namely, the heat content of the excess air at the temperature of the products of combustion escaping to the stack. Leakage of air through the walls of the furnace and boiler setting increases the excess air loss to the stack without effecting, in general, any corresponding gain in combustion efficiency. Considerable saving in fuel may often be made simply by reducing leakage through cracks or openings in boiler settings.

For each kind of fuel, type of furnace and method of firing, there is a certain percentage of excess air which results in a minimum loss. The most economical percentage of excess air is determined for any given installation from analyses of the products of combustion, and it corresponds to that percentage of carbon dioxide at which the carbon monoxide amounts to only a few tenths of 1%. For hand-fired coal furnaces and older stoker installations with restricted furnace volume, the best carbon dioxide percentage is around 12% which represents about 50% excess air. Larger combustion chambers were later employed because it was thereby possible to reduce the excess air below 50% without producing much carbon monoxide. At high operating capacities, however, furnace temperatures became so high that slagging of refractory walls and formation of clinkers in fuel beds became excessive. Water-cooled walls have eliminated refractory troubles and permitted the most economical percentage of excess air to be used without reaching excessively high temperatures, so that in some of the most modern steam generator furnaces as high as 15 to 16% of carbon dioxide is attained in daily operation.

With gases and oils, the most economical percentage of carbon dioxide will, in general, be less than mentioned above for coal, although the excess air percentage may be lower by reason of the more intimate mixture of fuel and air that can be obtained with proper burners and furnaces. This is due to the larger percentage of hydrogen in these fuels which combines with oxygen-forming water that is not ordinarily included in analyses of products of combustion.

When burning pulverized coal, thorough mixing in the furnace of the fuel particles with the air is conducive to complete combustion with low excess air. This may be secured by means of turbulent firing where the coal and air streams impinge upon one another in the furnace; but while the volatile matter may be burnt within a small volume, a much larger furnace must be provided to give time for the fixed carbon particles to burn before they escape from the furnace. Finer pulverization will reduce the unburnt combustible loss at the expense of the use of more power for grinding the coal. For solid fuels burned on grates and stokers, the furnace shape as well as its size is important in securing thorough mixture.

Smoke is often taken as an indication of poor combustion, and so it may be. However, smoke is often due to the presence of fine particles of soot resulting from breaking down volatile matter by heating with insufficient air rather than to larger particles of unburnt fixed carbon. Hence a smoking furnace may be working at fairly high efficiency, while one with a clear stack may have a large excess air loss. Smoke may be prevented by using a low volatile fuel such as anthracite coal and coke, or by mixing air with the volatile matter more thoroughly and thereby insuring its complete combustion in the furnace.

Combustion losses are reduced by preheating the air. The maximum permissible preheat temperature is determined by the durability of grates or stoker parts. In pulverized coal firing, the preheat temperature is limited only by the durability of the preheater elements. There is an economic relation, however, between the cost of air preheater surface, economizer surface and boiler tube surface, which results in a minimum cost for the complete steam generating unit corresponding to a moderate air preheat temperature between 400° and 500° F.

If all the heat liberated by combustion and carried into the furnace in the preheated air were imparted to the products of combustion, very high furnace temperatures would be reached. Much lower temperatures actually obtain in boiler furnaces due to radiation. Radiation from the incandescent fuel and flames varies approximately as the fourth power of their absolute tem-

perature. With water-cooled walls, over one-half the heat of combustion is absorbed in the furnace by radiation from the incandescent fuel and flames This radiant heat will fuse any particles of ash which cannot be kept cool by adjacent water-cooled surfaces. Hence refractory baffles must be protected by two or more rows of boiler tubes on the furnace side or particles of ash adhering to them will fuse and form large slag masses. With pulverized coal firing, ash will melt on the furnace bottom unless cooled below its fusing temperature and protected from radiation by "screen tubes" While the melted ash may be run out of the furnace as molten slag, there is an additional furnace loss in the latent heat of fusion of this slag.

Boiler test codes adopted by engineering societies in various countries, define boiler efficiency as the ratio of the heat absorbed by the steam produced per unit weight of fuel burned, to the gross, or upper, heating value of the fuel as determined in a calorimeter where the moisture present in the fuel and formed from the hydrogen therein is condensed to water. In England, efficiencies are often guaranteed as based on the lower heating value, which is equal to the upper heating value minus $1{,}050\times(M+9H)$, where M = lb. of moisture and H = lb of hydrogen per lb. of fuel burned and 1,050 = latent heat of steam at atmospheric temperatures. (W L. DE BA.)

BOILERS AND STEAM GENERATORS

Boilers are of the following designs: return tubular, water tube, electric, steam generator

Return Tubular boilers consist of a shell 60 in. to 108 in. in diameter. The shells are made of several plates riveted together with the tubes acting as stay bolts for the heads. The gases pass through the tubes The boilers are limited in size to about 3,000 square feet. This type of boiler is used where small quantities of steam are required, at pressures not exceeding 250 lb. per square inch It is also used extensively for waste heat in the manufacture of open hearth steel and other processes, in marine work and for locomotives.

Water Tube Boilers are boilers in which the water passes through the tubes and the gases are on the outside of the tubes. One of the main advantages of this type of boiler is safety. The latent heat in hot water under pressure has a particularly destructive effect in case the pressure in the vessel is suddenly released By confining the water to tubes, the quantity of water in any particular part of the boiler is kept to a minimum and if a tube bursts, the resulting damage will be small Another advantage is that the size of the unit is limited only by the size of plates available Individual boilers containing 42,000 sq ft of heating surface were in operation in 1929 and single units containing 59,000 sq.ft. of heating surface in process of manufacture. This boiler is made in several different classes; *straight tubes with box headers* and both longitudinal and horizontal drums, *straight tubes with sectional headers,* and both longitudinal and horizontal drums, *bent tubes with vertical and semi-vertical tubes* and drums.

For box header boilers the headers are formed by riveting together two plates, spaced apart to form a boxlike structure. This construction is usually limited to 10,000 sq ft. on account of the difficulty of shipping larger plates and to pressures of about 400 lb per square inch The straight tube sectional header boiler is substantially of the same general cross-section as the box header except that in some cases there is a greater inclination of the tubes The headers are made of cast or forged steel and contain one or more vertical rows of tubes. This type of boiler has been built in sizes up to 35,000 sq.ft. and can be built larger and for pressures up to 1,400 lb. per square inch

Electric Boilers.—The electric boiler is used to generate steam or hot water where a small quantity of steam is required or in larger sizes where electricity can be secured at reasonable rates to improve the load factor of plants.

Steam Generators.—The advent of pulverized coal (*see* PULVERIZED FUEL) crystallized the design of complete steam generating units giving consideration to the proper furnace volume and co-ordination of radiant and convection heating surface, superheater, economizer and air preheater. Such construction can be fired by oil, gas or pulverized fuel It can readily be built for pressures up to 2,000 lb per square inch The fuel may be introduced at several points and sometimes the burners are located at the top of the furnace with the gases passing downward. In other designs the fuel is introduced at the bottom with the gases passing upward through the furnace. The economizer and fan may be placed directly back of the convection surface and the fans directly above the air preheater so that the duct work, with its chances for radiation and leakage, is reduced to a minimum. Some steam generator units give efficiencies of 89%.

Drums.—When built for pressure of 100 to 350 lb. all boiler drums were constructed of rolled plates formed on bending machines and riveted together. As the pressure increases the plate is necessarily thicker, making it more difficult to form plates and drive the rivets. It is generally accepted in 1929 that riveted drums should be limited to not more than 2½ inches. Up to 1928 a few boiler drums less than 2 in. thick have been constructed by forge welding. In Europe, but not in the United States up to 1929, drums have been constructed of drawn seamless tubes. For drum thickness of 2½ in and over the most satisfactory method in use in America, is forged steel drums An ingot, containing nearly twice the metal necessary for the completed drum, is pierced and hammered out over a mandrel, until the required length and diameter are obtained. The forging is then bored to the required diameter and the outside of the shell is turned to the proper diameter The ends are heated and necked in so that the heads are integral with the drum After the forging process is completed the drums are normalized by heating and proper cooling to remove stresses set up by forging. There are drums as large as 40 in in diameter and with shells 5¼ in. thick

In the United States the steel for riveted and forge-welded boiler drums must conform with the chemical and physical characteristics given in the A S M E boiler code Alloy steels containing copper have been tried in one or two individual cases. Some experiments have been made using other alloy steels in an effort to prevent scale and corrosion but the results of such tests are not yet available (1929).

Large Units.—For large capacity units, the bent tube boiler has been found to give the most economical results. At low ratings, below 300%, the straight tube boiler has been found to give lower exit temperature but above these ratings the bent tube boiler gives approximately the same and in some cases lower exit temperatures. At high ratings the draft loss of the bent tube boiler is much less It is customary in designing large boilers to place two bent tube boilers in the same setting and facing each other With this method of construction, firing is usually done from two sides. There are no bridge walls. The radiation losses are low, the gases are most thoroughly mixed before entering the boiler surface, the unit is compact and the drums are practically one-half the length that would be required for a single unit with firing from one side Such units are now in operation delivering over 600,000 lb of steam per hour and there are in process of construction, units to deliver 1,000,000 lb of steam per hour. (*See* BOILER MAKING; BOILERS.) (J. B. C.)

MECHANICAL STOKERS

A mechanical stoker is a device for stoking or firing a furnace by mechanical means In its broadest interpretation mechanical stoking would include the mechanical feeding of any kind of fuel to a furnace, but in common usage the term is limited to the firing of solid fuels such as coal and coke. The earliest form of mechanical stoker was an endless conveyor with two endless chains situated near the sides of the furnace and engaging sprockets mounted on shafts situated at the front and rear. Transverse grate bars were attached to these chains to form the fuel-supporting surface, one shaft was provided with means for driving the chains and grate so that the top surface moved through the furnace from front to rear. A hopper fixed at the stoker front supplied fuel to the grate and natural or chimney draft provided air for combustion which was admitted through the grate and fuel bed. The speed of the grate was regulated so that the fuel

was burnt out during its travel through the furnace and the resultant ash and refuse was discharged into a pit as the grate made the return bend around the sprockets on the rear shaft. A natural draft chain stoker is applicable to non-coking or free burning bituminous coals.

A modification of this type of stoker provides for the use of forced draft supplied by a fan or blower for admitting the air for combustion. With this provision, higher rates of combustion are made possible, and, with suitable forms of grate surface, a wide variety of fuels may be burned successfully. The forced draft travelling grate stoker is frequently used for burning anthracite fines, coke fines and lignite coals. A similar stoker differing in detail is used successfully with free burning bituminous coal.

The overfeed, inclined grate natural draft stoker is used to a limited extent for burning bituminous coals at moderate ratings under small boilers. The fuel is fed from the hopper usually at the front, to stepped grates which are rocked by mechanical means to impart a downward travel of the fuel during combustion and to deposit the ash and refuse at the rear, on dump trays which are lowered by hand at intervals to discharge the ash into a pit below.

Underfeed stokers, as the name suggests, introduce the fuel below the surface of the fuel bed. The volatile constituents of the coal are distilled off and pass up through the incandescent fire where they are rapidly ignited and burned without producing smoke. Forced draft is used with this type of stoker. While practically every kind of bituminous coal has been successfully burnt on underfeed stokers, this method of firing finds its greatest field for use with coking coals which during combustion tend to form cohesive coke masses that must be broken up to insure uniform fuel bed conditions. Underfeed stokers may be broadly subdivided into two general classes—single retort stokers and multiple retort stokers.

In single retort stokers the coal is commonly fed from a hopper at the stoker front into a centrally situated trough or retort by means of a pusher driven by a steam actuated piston or by an electric motor. The bottom of the retort is movable and is slid back and forth so as to distribute the fuel uniformly through the retort from front to back. Each new charge of coal introduced serves to push an equal volume of fuel out of the top of the retort and on the grate bars which extend transversely from the sides of the retort. Alternate grate bars are movable and are connected to the stoker drive so as to impart a slight slicing motion which serves to maintain a porous fuel bed, to distribute the burning fuel across the stoker and to carry the ash and refuse to dump trays placed along each furnace side wall. Air for combustion is supplied under pressure by a fan or blower and is admitted to the fuel bed through openings along the sides of the retort and between the grate bars.

The multiple retort underfeed stoker comprises a series of retorts (usually inclined) mounted side by side across the furnace width. Coal is fed from a hopper, fixed at the stoker front, by rams connected to a crank shaft and driven through proper reducing gearing by an electric motor or other means. Secondary rams, situated in the bottom of the retorts, serve to break up the coke masses, to distribute the fuel over the stoker and to deposit the ash and refuse either on dump grates or into a pit at the rear where grinder rolls crush the refuse and discharge it into a pit below. Air for combustion is supplied under pressure by a fan, through nozzles or tuyeres arranged in longitudinal rows between adjacent retorts.

Mechanical stokers are usually controlled by regulators which are set to maintain a predetermined steam pressure and which are actuated by changes in this pressure. A drop in steam pressure causes an increase in stoker and fan speed so that more coal and air are admitted to correct the falling steam pressure. An increase in steam pressure causes a decrease in the amount of coal and air admitted. Stokers so equipped maintain constant steam pressure automatically and are called "automatic mechanical stokers." Mechanical stokers are principally used for firing stationary steam boilers and metallurgical furnaces. However, types have been developed and satisfactorily applied to locomotives and marine boilers. (C. STR.)

OTHER EQUIPMENT

Superheaters are used to increase the temperature of steam without increasing its pressure. The furnace gases furnish the heat, either in the furnace, among the boiler tubes or in the exhaust to the stack where some lost heat can be recovered. For a discussion of superheaters and superheat *see* BOILERS; STEAM.

Reheaters are used to prevent loss of superheat and the formation of moisture when steam is used in turbines. (*See* BOILERS.)

Air Preheaters.—The exhaust gases coming directly from the furnace or from the economizers are used in air heaters or preheaters to heat the air that is to be used for combustion in the furnace, thus making use of otherwise lost heat. (*See* BOILERS.)

Feed Water Heaters.—Before water fed to a boiler can be converted into steam it must first be heated to the temperature corresponding to the pressure in the boiler. This feed water is heated in open heaters, closed heaters or economizers, either to that or to a lesser temperature, depending on the plant. The first two types of feed water heaters use live or exhaust steam to obtain heat, the last uses the exhaust gases from the furnaces. (*See* ECONOMIZERS; BOILERS; ELECTRICAL POWER GENERATION.)

Evaporators and De-aerators are used to supply loss in feed water and to remove the air dissolved in the water in the condenser. (*See* ELECTRICAL POWER GENERATION.)

SELECTION OF STEAM GENERATING EQUIPMENT

Steam generating equipment may be considered as comprising not only the boiler and furnace but all auxiliaries necessary or desirable from the point of delivery of the coal to the stop valve on the boiler. A proper evaluation of factors which determine the correct selection of the necessary or desired equipment can only be made by an engineer thoroughly familiar with all the factors, their relations and a knowledge of costs, values and economics.

In a modern utility plant the steam end may and frequently does include in addition to the boiler a water-cooled furnace—steam superheaters and re-heaters—mechanical stokers of various types; burners for pulverized coal or oil; economizers and air preheaters; induced and forced draft fans or blowers and their necessary motor or turbine drive; ducts and flues for conducting the air and flue gas to desired points; chimney and dampers; cinder or dust catchers; boiler feed pumps and feed water regulators; soot blowers for the boilers; economizers and air-heaters; condensers; blow down valves; heat inter-changers to abstract heat from boiler blow down; open or closed feed water heaters; deaerators; a feed water treating plant or evaporators.

The complete coal and ash handling system from the railroad siding to the coal bunkers may include a car dumper, track hopper, screens, crushers, magnetic separators, conveyors, skip hoists, locomotive-crane and all equipment necessary for storing and reclaiming coal. If coal is pulverized there will be dryers, pulverizing mills with piping collectors, conveyors, feeders, burners and necessary motors. Ash may be handled by cars, conveyors or by water in sluices or grab buckets. Other auxiliary equipment may include a combustion control system with elaborate inter-locking of the electrical equipment. Pressure and draft gauges, thermometers, steam flow meters and gas analysers, all of the indicating or recording type, will also be found.

The problem of the selection of proper equipment may be very simply stated. Equipment should be selected that will produce steam at the lowest total cost for the expected life of the plant, with the required reliability. The weight given to various factors will differ in various types of plants. In public utility plants where the fuel cost is about half the total cost of operation greater weight is given to economy, this factor being modified by the cost of fuel. In some industrial plants operating only ten hours per day with cheap coal, first cost may be a major factor. There are certain processes requiring continuity of steam pressure or power in which a failure of either or both for a few minutes may ruin material valued at thousands of dollars. In such cases reliability usually secured by duplication or excess spare capacity should be one of the major factors considered. The total cost of

steam generation is made up of fixed or capital costs and operating costs. The fixed charges or costs are made up of interest on first cost, taxes, insurance, depreciation or obsolescence. The operating costs include fuel; water; maintenance material-repairs; supplies of oil, tools and chemicals; operating labour; maintenance labour; clerical salaries and operating supervision. Generally, by increasing the capital cost, the operating cost may be reduced. High efficiency can be obtained by high capital expenditure. However, depending on the fuel cost and many other factors, a point is reached where the fixed charges of additional equipment equal the saving obtained by that equipment and any additions beyond that point result in fixed charges in excess of savings.

One of the important factors having a major bearing on economy and in capital costs is the plant capacity factor, sometimes named load factor. The capacity factor is the total load per year expressed in any suitable units divided by the rated or normal capacity of the units times 8,760 hours per year or the relation of the actual annual load carried to the annual load if units were operated at normal capacity every hour of the year.

In view of the complexity of the many factors affecting the selection of steam generating equipment and their interrelation it is only possible to list them in their major relations and group these relations as logically as possible The considerations listed below are the most usual There may be others peculiar to certain specific problems

Type of load	Power	Utility Industrial
	Power and Heating	Utility Industrial
	Process	
	Heating	
Capacity factor	Relation of—to economy	
	Effect of—on type	
	Effect of—on first cost

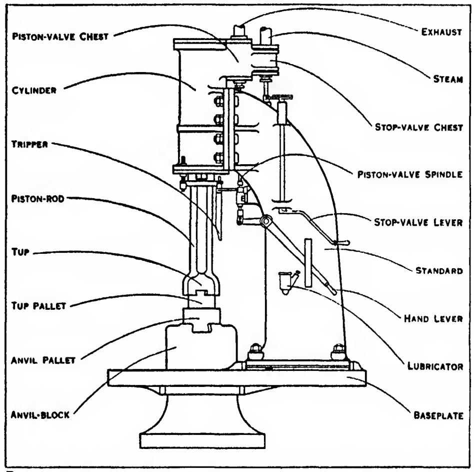
*The size, type and operating rate of boilers may be limited by quality of water. (J. Van Br)

STEAM-HAMMER. Steam-hammers are made in sizes ranging from ½ cwt. to about 12 tons. The size is merely a nominal rating, being the weight of the falling parts—piston, rod, tup, pallet—and takes no account of the pressure of steam which drives the piston down for the blow. As an approximate guide, however, it may be stated that the steam pressure in a 5-cwt. hammer gives a crushing effect on hot iron equal to a load of about 30 tons. Types of hammers are classified in three principal forms, the overhanging with slide, the arch and the Rigby (*see* drawing). In the last-named there is plenty of clearance space for the smith to manipulate work above and around the anvil-block, and the piston has a longer stroke and gives more power than corresponding hammers of other types. The overhanging type hammer has slides reaching down to guide the tup accurately, an advantage in many cases of forging, including that done in dies. The arch form has two standards between which the tup is also run in guides, and it is much used for forgework of heavy description, being a very rigid construction. The frame is often built of rolled steel plates and angles instead of cast-iron or cast-steel The operating mechanism of the B. and S. Massey hammer shown comprises the stop-valve lever which regulates the quantity of steam admitted to the hammer, and the hand-lever that is moved to strike light or heavy blows, or to hold work between the pallets as in a vice, for bending purposes, etc. The steam is used expansively, with resulting economy, by the action of the tripper, which begins to close the piston-valve after the tup has moved a certain distance A self-acting valve-gear can be applied to any type of hammer, so as to cause the hammer to work automatically. Many special shapes of hammer framings and anvils are built for specific purposes. Control is in some cases effected by a treadle, so that one man can use the hammer Compressed air may be utilized instead of steam, should it not be convenient to furnish a supply of the latter The lubricator attached to the side of the frame consists of a hand pump with which



B AND S MASSEY STEAM HAMMER WHICH DELIVERS BLOWS IN ACCORDANCE WITH THE MOVEMENTS OF THE HAND LEVER

the cylinder and valves can be oiled at any moment without stopping the hammer. To secure efficient results the anvil-block must be of great weight, and supported on a mass of timbering resting on deep concrete or rock. The base also rests on timbers and concrete. STEAM SHOVEL or **NAVVY.** A form of excavator which drags a bucket or shovel, at the end of a pivoted arm, from a surface position up to the top of a cutting or other place to be excavated, filling the bucket meanwhile. The mouth has steel cutting teeth or tines for easy penetration When the bucket is filled, discharge is made into wagons or elsewhere by opening a door at the bottom. The machine is a very powerful modified type of jib crane, specially constructed for fast and severe duty, with a great amount of steel construction, and extra hard parts of manganese steel for those subjected to excessive friction and exposure to grit The pivoted arm either has a fixed swing from its pivotal point about half-way up the jib, or the swing may be varied by racking the arm to or fro. As the crane stands still during a succession of cuts the depth of penetration has to be regu-

lated to suit the capacity of the bucket. With the fixed arm design this is done by varying the radius of the jib, and with the racking arm by the movement of the latter alone. Bucket capacity varies from ½ cubic yard to about 15 cubic yards. The drive is by steam (the oldest system) but alternatively may be by petrol or paraffin motor, by electric motors, or Diesel-electric. The last-mentioned possesses the advantage of flexibility similar to the steam drive, *e.g.*, it will give a sudden access of power (not possible with a direct Diesel drive) due to the high torque characteristic of an electric motor. Shovels are either mounted on plain wheels, or on railway wheels; or caterpillar tracks are fitted, to transfer the machine as required on any ground. Some of the largest shovels are built for "stripping" or removing a deep overburden of earth covering ironstone or coal. The biggest machine yet built, a Marion, for this duty weighs 1,400 tons, and carries a 15 cubic yard bucket at the end of an arm 120 feet long. Eight caterpillar tracks sustain the shovel, with hydraulic devices to compensate for uneven ground. The three motions, hoisting the bucket, crowding or thrusting it into the cut, and rotating, are performed by separate electric motors. This is similar to the practice in steam shovels, which carry separate engines for the three functions.

Shovels can be adapted to work grabs when this provision is necessary for handling piles of material and loose excavation. The *dragline* excavator is either a machine solely used for this special kind of excavating, or is a modified shovel, the change being made rapidly. Instead of thrusting a bucket, it drags it towards the machine, being suitable for reclamation, canalization, drainage, foundation work, etc. The *skimmer scoop* acts in a horizontal direction, the jib of the navvy being set parallel with the ground, and the bucket dragged along under it, so that the surface of a road can be torn up. Also the loose debris may be scooped up and loaded into a lorry. A *back-acting trencher* has the bucket arm pivoted at the top end of the jib, the latter being lowered to a suitable distance above the ground. As the bucket is reversed to the normal direction for a steam navvy it is dragged towards the machine excavating a trench, and the machine retreats as the work progresses. Narrow and deep trenches can be cut rapidly with this adaptation of the navvy. *See* the article EXCAVATION.

STEDMAN, EDMUND CLARENCE (1833–1908), an American poet and critic, was born of Puritan stock at Hartford (Conn.), Oct. 8, 1833. From his mother he inherited his gift for writing; but at six years of age, his father having died, he was separated from her and reared by his father's people. A sensitive, lonely, rather rebellious youth, although he won several prizes for composition, he was rusticated after two years at Yale, and was not allowed to return. In 1871, however, the college conferred on him the B.A. and M.A. degrees, and in 1895 the degree of LL.D. After directing two Connecticut papers and embarking in business in New York, Stedman became connected with the New York *Tribune*, and in 1860 went to the *World* as editor, later becoming its war correspondent. A clerkship in Washington formed an interlude, but much of his life was spent in trading on the New York Stock Exchange, of which he edited a history (1905). He edited a volume of *Cameos* from Landor (with T. B. Aldrich, 1873), *A Library of American Literature* (11 vol. 1887–90), *The Works of Edgar Allan Poe* (with G. E. Woodberry, 10 vol. 1894–95), *A Victorian Anthology* (1895) and an *American Anthology* (1900). In addition to a large number of ephemeral reviews, he published *Victorian Poets* (1875), *Poets of America* (1885), and *The Nature and Elements of Poetry* (1892), books which show the poet's critical insight, technical knowledge, and high standards of workmanship. His most enduring place in literature, however, is due to his poetry—the deep serious note of his war lyrics or the whimsical fantasy of "Pan in Wall Street." The title of his rather conventional first book, *Poems, Lyrical and Idyllic* (1860), sounds the keynote of his work. Always a lover of beauty, he refused to be swayed from his ideals by the contemporary popularity of such *jeux d'esprit* as "The Diamond Wedding." As a result he has to his credit a group of fine and true lyrics such as the "Creole Lover's Song" and some commendable longer poems—*Alice of Monmouth; An Idyl of the Great War* (1863), *The Blameless Prince* (1869), and the elaborate commemorative ode on Hawthorne (read before the Harvard Phi Beta Kappa Society, 1877). He died in New York on Jan. 18, 1908.

STEED, HENRY WICKHAM (1871–), British journalist, was born on Oct. 10, 1871, at Long Melford, Suffolk. He studied economics, philosophy and history at Jena, Berlin and Paris universities, and in 1896 joined the staff of *The Times* as acting correspondent in Berlin, and was appointed correspondent in Rome in 1897. Transferred thence to Vienna in 1902 as correspondent for Austria-Hungary, he remained there until 1913 when he returned to London, and was appointed foreign editor of *The Times,* in Jan. 1914. In 1913 he published *The Habsburg Monarchy,* in which the internal condition of Austria-Hungary was critically examined and the possibility of a European war discussed. During the World War, Steed was mainly responsible for the foreign policy of *The Times* and, in 1918, was chosen to frame the policy of Lord Northcliffe's Department for Propaganda in Enemy Countries. He was sent on an official mission to the Italian front where he was authorized by the Allied Governments to promise independence to the subject Habsburg peoples. He helped also to arrange, in April 1918, the Rome congress of the oppressed Austro-Hungarian races. In Feb. 1919 he was appointed editor of *The Times,* and held this post until Nov. 1922. After relinquishing the editorship of *The Times* Steed published *Through Thirty Years* (1924), in which he related his experiences of European politics between 1892 and 1922. In 1923 he acquired the control of *The Review of Reviews,* of which he became editor.

STEELE, SIR RICHARD (1672–1729), Irish man of letters in the reign of Queen Anne, is inseparably associated in the history of literature with his personal friend Addison. The two were born in the same year. Steele, the senior by less than two months, was baptized on March 12, 1672 in Dublin. His father, also Richard Steele, was an attorney. He died before his son had reached his sixth year, but the boy found a protector in his maternal uncle, Henry Gascoigne, secretary and confidential agent to two successive dukes of Ormonde. Through his influence he was nominated to the Charterhouse in 1684, and there first met with Addison. Five years afterwards he proceeded to Christ Church, Oxford, and was a postmaster at Merton when Addison was a demy at Magdalen. Their schoolboy friendship was continued at the university, and probably helped to give a more serious turn to Steele's mind than his natural temperament would have taken under different companionship. Without waiting for a degree he volunteered into the army, and served for some time as a cadet "under the command of the unfortunate duke of Ormond" (*i.e.,* the first duke's grandson, who was attainted in 1715). This escapade was made without his uncle's consent, and cost him, according to his own account, "the succession to a very good estate in the county of Wexford in Ireland." He found a patron in Lord Cutts, to whom he dedicated a poem on the funeral of Queen Mary (1695). Cutts took the gentleman trooper into his household as secretary, made him an officer in his own regiment, and ultimately procured for him a captaincy in Lord Lucas's regiment of foot. A duel which he fought with Captain Kelly in Hyde Park in 1700, and in which he wounded his antagonist dangerously, inspired him with the dislike of duelling that he showed to the end of his life. Steele won William III.'s favour (too late to be of practical use) by a timely reference to him in *The Christian Hero,* his first prose treatise, published in April 1701. Steele complained that the reception of *The Christian*

Hero by his comrades was not so respectful; they persisted in trying him by his own standard, and would not pass "the least levity in his words and actions" without protest. He therefore determined to clear his character of the charge of undue solemnity by writing a comedy, *The Funeral* (1701). With this play he began his work of reconciling wit, good humour and good breeding with virtuous conduct which he was afterwards to accomplish in the famous essays in the *Tatler* and the *Spectator* In his next comedy, *The Lying Lover; or, the Ladies' Friendship* (1703), based on Corneille's *Menteur*, Steele's moral purpose was directly avowed, and the play, according to his own statement, was "damned for its piety." *The Tender Husband*, an imitation of Molière's *Sicilien* (in April 1705), was more successful. It was seventeen years before Steele again tried his fortune on the stage with *The Conscious Lovers*, the best and most successful of his comedies, produced in December 1722

The Tatler and the Spectator.—In 1707 Steele was given the office of gazetteer. The *Gazette* gave little opening for the play of Steele's lively pen, his main duty, as he says, having been to "keep the paper very innocent and very insipid"; but the position gave him insight into journalism. The *Tatler* made its first appearance on April 12, 1709 It was partly a newspaper, a journal of politics and society, published three times a week. Steele's position as gazetteer furnished him with special advantages for political news, and as a popular frequenter of coffee-houses he was at no loss for social gossip. He gradually introduced into the *Tatler* as a special feature essays on general questions of manners and morality.

Steele was always in want of money. He had £300 a year from his gazetteership (paying a tax of £45), £100 as gentleman waiter to Prince George, £850 from the Barbadoes estates of his first wife, a widow named Margaret Stretch, and some fortune by his second wife—Mrs. Mary Scurlock, the "dear Prue" of his charming letters. But he lived in considerable state after his second marriage, and before he started the *Tatler* was borrowing money. The assumed name of the editor was Isaac Bickerstaff, but Addison discovered the real author in the sixth number, and began to contribute in the eighteenth. The success of the *Tatler* was established before Addison joined him, and Addison contributed to only forty-two of the two hundred and seventy-one numbers that had appeared when the paper was stopped, obscurely, in January 1711

Only two months elapsed between the stoppage of the *Tatler* and the appearance of the *Spectator*, which was the organ of the two friends from March 1, 1711 to Dec. 6, 1712 Addison was the chief contributor to the new venture, and the history of it belongs more to his life. Nevertheless, it is to be remarked as characteristic of the two writers that in this as in the *Tatler* Addison generally follows Steele's lead in the choice of subjects. The first suggestion of Sir Roger de Coverley was Steele's although it was Addison that filled in the outline.

Steele projected various journals in the next years, most of them, such as the *Englishman* (1733), and the *Reader* (1714), *Town Talk*, *Tea Table* and *Chit Chat*, very short lived; though the *Guardian* (1713) had 176 numbers. Steele's most famous political paper, the *Plebeian* (1718) embroiled him in a controversy with Addison A pamphlet, *An Apology for Himself and his Writings* (1714) is important biographically.

Later Life.—The fortunes of Steele as a zealous Whig varied with the fortunes of his party. Over the Dunkirk question he waxed so hot that he threw up a pension and a commissionership of stamps, and went into parliament as member for Stockbridge to attack the ministry with voice and vote as well as with pen. But he had not sat many weeks when he was expelled from the house for the language of his pamphlet on the *Crisis*, which was stigmatized as seditious. The *Apology* already mentioned was his vindication With the accession of the House of Hanover his fortunes changed. Honours and substantial rewards were showered upon him He was made a justice of the peace, deputy-lieutenant of Middlesex, surveyor of the royal stables, governor of the royal company of comedians—the last a lucrative post—and was also knighted (1715) After the suppression of the Jacobite rebellion he was appointed one of the commissioners of forfeited estates, and spent some two years in Scotland in that capacity. In 1718 he obtained a patent for a plan for bringing salmon alive from Ireland. Differing from his friends in power on the question of the Peerage Bill he was deprived of some of his offices, but when Walpole became chancellor of the exchequer in 1721 he was reinstated. With all his emoluments however the imprudent, impulsive, ostentatious and generous Steele could never get clear of financial difficulties, and he was obliged to retire from London in 1724 and live in the country. He spent his last years on his wife's estate of Llangunnor in Wales, and, his health broken down by a paralytic seizure, died at Carmarthen, Sept 1, 1729

A selection from Steele's essays, with a prefatory memoir, has been edited by Austin Dobson (1885; revised 1896). *See* also *Selected Essays* (1907) ed. L. E Steele; and *Letters of Richard Steele* (1928), ed. R. B. Johnson. Dobson contributed a biography to Andrew Lang's series of *English Worthies*, in 1886. In 1889 an exhaustive life was published by G. A Aitken, who also edited Steele's plays (1898) and the *Tatler* (1898).

STEELS, ALLOY. Alloy steels may be divided into two main groups, namely:—(*a*) Alloy tool steels, which are dealt with under "tool steels," and other headings; (*b*) Alloy steels for engineering purposes, which are here briefly described This group includes the high tensile steels, with useful mechanical properties developed by heat treatment, the alloy case-hardening steels, which are carburized and hardened before putting into service, and the non-magnetic, austenitic steels, the mechanical properties of which cannot be varied greatly by any form of heat treatment.

High Tensile Alloy Steels.—The chief use of the hardenable alloy steels lies in their ability to be made both strong and tough by suitable heat treatment, that is to say, they can combine high tensile properties with superior resistance to shock, thus permitting the engineer to design various parts of considerably smaller size than would otherwise be possible.

It has been found, as the result of the work of many investigators, that the desired combination of strength and toughness is most highly developed when the constituents of the steel are in the finest state of division This condition is secured by heating the steel to such a temperature as will cause the different constituents to completely interdiffuse with each other, producing what the metallurgist calls a solid solution, and retaining this by cooling at a sufficiently rapid rate and then reheating to cause a partial or complete re-precipitation of the constituents from this solid solution

The addition to steel of other metals like nickel, chromium, molybdenum, etc , increases the amount of lag, that is the difference between the temperatures of the change points on heating and cooling The greater the amount of this lag, the more easy is it to retain the steel in the state of solid solution, *i e* , to harden it, so that quenching in oil is sufficiently rapid with many of these alloy steels, and if still larger amounts of certain elements are present, as for example with some nickel-chromium steels, the amount of lag is so great that bars of normal size are hard even if allowed to cool in air.

Nickel steels, which are amongst the most commonly used high tensile alloy steels, may contain 1 to 5% nickel, with a carbon content varying from ·25 to ·45%, according to the mechanical properties required The presence of only 1% nickel makes the steel more responsive to heat treatment, producing, in smaller sizes, excellent mechanical properties of the order of 35 to 45 tons tensile strength with high resistance to shock as expressed by the notched bar impact test. Steel containing 3% nickel is, however, more popular, and readily gives a tensile strength of 45 to 55 tons per square inch with an izod impact figure of 40 ft. lb. The addition of 5% nickel produces a still stronger steel, having a tensile strength of 55 to 65 tons per sq in. with a similar impact value.

These nickel steels do not harden intensely when cooled in air, and this offers certain advantages for some purposes, as for instance in the making of drop forgings, which can be laid down after forging without any great fear of cracking. The nickel steels are hardened in oil from temperatures of 800° C to 850° C and tempered in the range 550° C to 650° C, according to the mechanical properties required.

The addition of chromium along with nickel increases the intensity of hardening, thus producing steels of higher tensile strength capable of hardening through their section in larger masses. There are a number of nickel-chromium steels in everyday use, which contain carbon ranging from ·25 to ·45%. The most generally used compositions are 1% nickel with 1% chromium, 2% nickel with 1% chromium, 3% nickel with ·5 to 1% chromium, 3·5 to 4·5% nickel with 1 to 2% chromium. Although the steels containing the lower amounts of nickel and chromium harden in air to a greater extent than nickel steels without chromium, they are generally hardened in oil from temperatures of 800° C to 830° C and tempered in the range 600° C to 650° C.

Steels containing the higher amounts of nickel and chromium will harden, in sizes up to say 3 in. diameter, to 100 to 110 tons per square inch when cooled in air from 800° to 820° C, whilst larger sizes are quenched in oil. Such steels are sometimes used in the hardened condition, but for other purposes are tempered to give 55 to 65 tons per square inch. To be always sure of obtaining good impact values with the nickel-chromium steels they should be rapidly cooled from the tempering heat. If allowed to cool slowly, some of them show a peculiar type of brittleness known as "temper-brittleness." Further, such steels when tempered in the range of 250° to 550° C are apt to be brittle. A small amount of vanadium is sometimes added to the nickel-chromium steels.

The addition of molybdenum to nickel-chromium steels produces a still higher tensile strength when tempering at similar temperatures, and has the further advantage of preventing the occurrence of temper-brittleness, so avoiding the necessity of rapid cooling after tempering, and also permitting the steel to be tempered at lower temperatures, thus enabling mechanical properties of the order of 65 to 80 tons per square inch to be obtained when desired, with an impact value of 40 to 20 ft. lb.

Another type of high tensile alloy steel is the chrome or chrome vanadium steels containing 1 to 1·75% chromium and 0 to ·3% vanadium. Such steels do not air harden but can be oil hardened from 840° C to 870° C and tempered from 600 to 700° C to give 45 to 65 tons per square inch. The effect of the small amount of vanadium on the mechanical properties is not very marked.

Other alloy steels such as chrome-molybdenum and nickel-molybdenum are made, which can be oil hardened and tempered to give similar mechanical properties to the earlier mentioned steels, but they are not at present so generally used. One of the chief advantages of the addition of molybdenum to steel lies in the influence it has, in the same way as tungsten, in producing a fine grained steel.

The previously mentioned steels are used for a variety of engineering purposes such as piston rods, axles, connecting rods, crankshafts, driving and propeller shafts, screw couplings, nuts and bolts, gears, steering levers, spindles, pinions, brake rods, gun tubes, torpedo air vessels, armour plates, etc.

In addition to the foregoing, the stainless steels containing 12 to 20% chromium, with 0 to 2% nickel, can be included in the category of high tensile alloy steels. They are capable of being hardened from temperatures of 900 to 950° C in air or oil up to a tensile strength of 70 to 100 tons per square inch, and can be tempered to give 40 to 65 tons, according to their composition.

The addition of silicon to steel also increases its hardening capacity and such steels are used particularly for the manufacture of springs. They contain ·40 to ·65% carbon, 1 to 2% silicon, and ·40 to 1·0% manganese, and are referred to as silico-manganese steels. The lower compositions are used for hardening in water, and the higher composition for oil-hardening. A silico-chromium steel is also used for springs which are oil hardened and tempered. Such steel contains ·50 to ·60% carbon, ·7% to 1·3% silicon and ·60 to 1·0% chromium.

Case-hardening Alloy Steels.—The most generally used alloy steels for case hardened parts are of low carbon content—·10 to ·20%—and may contain 1, 2, 3 or 5% nickel. Steels containing 3 to 4% nickel with ·60 to 1·5% chromium are also used to a less extent.

When carburizing, the parts are packed with a carbonaceous material in boxes, and heated. Experiments have shown that the most suitable temperature for rapid penetration without the formation of an excess of carbon on the extreme skin, is just above the upper critical temperature in the case of plain carbon steels. The time of carburizing depends upon the depth of penetration required, and is usually between 2 and 8 hours for general purposes. After carburizing, the part consists of a high carbon case and a low carbon core.

Owing to the temperature and length of time occupied in the carburizing operation, the steel is overheated, both in the case and the core, and if quenched directly from the carburizing box the steel would be brittle, and the case would be apt to shell off or crack. It is advisable to allow the carburised parts to cool in the box and reheat them to just above the upper critical temperature and cool in oil to refine the core, and then to reheat again to just above the lower critical temperature to refine and harden the case by quenching either in water or oil, depending upon the size of article and its composition. From what has been stated before, it will be seen that the upper critical temperature is lower the higher the nickel content of the steel. The refining temperature for steels containing say ·15% carbon with 1% nickel is 880° C, 2% nickel 860° C, 3% nickel 840° C, 5% nickel 800° C and the nickel chrome steels 850° C. The final hardening temperature varies from 760° C to 730° C according to the nickel content.

What composition of steel is used for any part depends upon what strength of core is required, and in choosing the steel the size of the article should be carefully considered, as the influence of mass upon the hardening effect is very marked.

Austenitic Alloy Steels.—This is a class of alloy steels characterized by low elastic limit values, and high ductility as revealed by the elongation in the tensile test. They are non-magnetic, and are not hardenable by quenching. Their hardness can be increased by cold working, with loss of some ductility, and after such treatment they become slightly magnetic, but can be fully softened again by heating to 1,000° to 1,100° C and cooling rapidly. They are more difficult to machine than other steels, and some of them—notably the high manganese steels, are commercially unmachinable although special drills have recently been perfected in America. Because of their low elastic limit they cannot be used for parts which are heavily stressed.

There are three well-known types of austenitic steels in use, firstly the manganese steels containing 12 to 14% manganese, which because of the rapidity with which they work-harden, are useful for such purposes as tramway points and crossings, which demand resistance to abrasion, combined with toughness.

Steel containing high amounts of nickel are also austenitic. A steel containing 25% nickel is used chiefly for parts of electrical machinery, and in some cases for its resistance to certain forms of corrosion and a special alloy containing about 36% nickel is useful because of its extremely low coefficient of expansion.

In the same class are the stainless steels containing 10 to 20% chromium and 6 to 25% nickel which are finding an extended use because of their superior resistance to many forms of corrosion, and also because of their strength at high temperatures, and resistance to oxidation.

(*See* also IRON AND STEEL, ALLOYS, and the various types of steels under their own headings.) (F. A.)

STEELTON, a borough of Dauphin county, Pennsylvania, U.S.A., 3 m. S.E. of Harrisburg, on the Susquehanna river; served by the Pennsylvania, the Reading and the Steelton and Highspire railways. Pop. (1920) 13,428 (21·6% foreign-born white and 14·7% negroes). It has vast steel works and various smaller manufacturing industries, and there is a large limestone quarry within its limits. A town called Baldwin was laid out here in 1866, and the present name was adopted for the borough in 1880.

STEEL WOOL, a mild abrasive commonly used to clean or polish metals and metallic objects. It is of great practical use in the japanning, plating and moulding rooms of factories. In rubbing down metallic articles to attain a fine finish, steel wool achieves much the same results as pumice. Steel wool is also used to clean rusty and tarnished hollow-ware.

STEELYARD, MERCHANTS OF THE, Hansa merchants who settled in London in 1250 at the steelyard on the riverside, near Cosin lane, now Ironbridge Wharf. Henry III. in 1259, at the request of his brother Richard of Cornwall, king of the Romans, conferred on them important privileges, which were confirmed by Edward I. It was chiefly through their enterprise that the early trade of London was developed, and they continued to flourish till, on the complaint of the Merchant Adventurers in the reign of Edward VI, they were deprived of their privileges. They succeeded in maintaining a footing in London till 1597.

See Stow, *Survey of London* (1598); Lappenburg, *Urkundliche Geschichte des hansischen Stahlhofes zu London* (Hamburg, 1851); Pauli, *Pictures of Old London* (1851), Ehrenberg, *Hamburg und England im Zeitalter der Königin Elizabeth* (Jena, 1896).

STEEN, JAN HAVICKSZ (1626–1679), Dutch subject-painter, was born at Leyden in 1626, the son of a brewer. According to Houbraken he studied under Nicolas Knupfer, a German artist, at Utrecht, and under Jan van Goyen, whose daughter he married in 1649. In November 1646 he enrolled himself as a student of the university at Leyden and in 1648 he was one of the founders of the Guild of St. Luke in that city. He settled at The Hague in 1649, and at Delft in 1654. In 1657 he is said to have been a brewer at Delft. He is repeatedly mentioned in documents in the Delft archives during 1656–57. He was a resident of Haarlem during the years 1661–69. He then moved to Leyden, where he received permission to open a tavern in 1672. In 1673 he took a second wife, Maria van Egmont, the widow of a Leyden bookseller. He died at Leyden Feb. 3, 1679.

The works of Jan Steen are distinguished by correctness of drawing, admirable freedom and spirit of touch, and clearness and transparency of colouring. But their true greatness is due to their intellectual qualities. In the wide range of his subjects, and their dramatic character, he surpasses all the Dutch figure-painters, with the single exception of Rembrandt. His productions range from the stately interiors of grave and wealthy citizens to tavern scenes of jollity and debauch. He painted chemists in their laboratories, doctors at the bedside of their patients, card-parties, marriage feasts—even religious subjects, though in these he was least successful. His rendering of children is especially delightful Portraits from his brush are comparatively rare.

The National Gallery contains three pictures by Jan Steen, of which the "Music Master" is the most important, and other excellent examples of his art in England are preserved in the Royal, the Bute, and the Northbrook collections, at Apsley House and Bridgewater House, and in the galleries of The Hague, Amsterdam, and the Hermitage, St Petersburg (Leningrad). A remarkably fine example of his work is the "Grace Before Meat" in the collection of Charles Morrison, London.

See Hofsteede de Groot, *Catalogue of Dutch Painters* (1907); F. Schmidt Degener, *Jan Steen* (1927) (trans by G Renier).

STEENKIRK or STEENKERKE, a village in the Belgian province of Hainaut, on the river Senne, famous for the battle of Steenkirk (Steinkirk, Estinkerke) fought on July 23–Aug. 3, 1692 between the Allies (*see* GRAND ALLIANCE, WAR OF THE) under William III. of England and the French commanded by the duke of Luxemburg. Previous to the battle the French army lay facing north-west, with its right on the Senne at Steenkirk and its left towards Enghien, while the army of William III. was encamped about Hal. William, seeing the opportunity of surprising a part of the enemy's forces and having forced a detected spy to give Luxemburg misleading news, set his army in motion before dawn on Aug 3 to surprise the French right about Steenkirk. The advanced guard, mainly English and Danish infantry, under the duke of Württemberg, deployed close to the French camps ere Luxemburg became aware of the impending blow; at this moment the main body of the army farther back was forming up after the passage of some woods. When the fight opened, Luxemburg was completely surprised, and could do no more than hurry the nearest foot and dragoons into action as each regiment came on the scene. But the march of the Allies' main body had been mismanaged; while Württemberg methodically cannonaded the enemy, waiting for support and for the order to advance, the Allies' main body, which had marched in the usual order, one wing of cavalry leading, the infantry following, and the other wing of cavalry at the tail of the column, was being hastily rearranged in rear. A few battalions only had come up to support the advanced guard when the real attack opened (12.30). The advanced guard had already been under arms for nine hours, and the march had been over bad ground, but its attack swept the first French line before it. The English and Danes stubbornly advanced, the second and third lines of the French infantry giving ground before them, but Luxemburg was rapidly massing his whole force to crush them, and meanwhile the confusion in the allied main body had reached its height. Count Solms, who commanded it, ordered the cavalry forward, but the mounted men, scarcely able to move over the bad roads and heavy ground, only blocked the way for the infantry. Some of the English foot, with curses upon Solms and the Dutch generals, broke out to the front, and Solms, angry and excited, thereupon refused to listen to all appeals for aid from the front. No attempt was made to engage and hold the centre and left of the French army, which hurried, regiment after regiment, to take part in the fighting at Steenkirk. William's counter-order that the infantry was to go forward, the cavalry to halt, only made matters worse, and by now the advanced guard had at last been brought to a standstill. At the crisis Luxemburg had not hesitated to throw the whole of the French and Swiss guards into the fight, and as, during and after this supreme effort, more and more French troops came up, the Allies were driven back, contesting every step against weight of numbers. Those troops of the main body, foot and dragoons, which succeeded in reaching the front, served only to cover and to steady the retreat of Wurttemberg's force, and, the *coup* having manifestly failed, William ordered the retreat. The Allies retired as they had come, their rear-guard—of grenadiers from the British regiments—showing too stubborn a front for the French to attack. The latter were indeed in no state to pursue. Over eight thousand men out of only about fifteen thousand engaged on the side of the Allies were killed and wounded, and the losses of the French out of a much larger force were at least equal. Contemporary soldiers affirmed that Steenkirk was the hardest battle ever fought by infantry

STEEPLECHASE, a variety of horse-racing not run on the flat, but either across country or on a made course with artificial fences, water-jumps, etc The name is sometimes used in connection with cross-country running on foot or of a race on a made course over hurdles and other obstacles. In Great Britain point to point Steeplechases held under the control of the M.F H Association, now represent the nearest approach to steeplechasing in its earlier days. The proficiency in jumping which ought to be characteristic of a first-class steeplechaser is often conspicuous by its absence nowadays when all too often a course of racing over hurdles is thought to be a sufficient preparation for racing over the regulation fences, built up in accordance with the instructions of the British National Hunt Committee.

As applied to racing of this class the term "steeplechase" is misapplied but serves as a convenient definition. It is also given to an English variation of the old French game of Goose (*q.v*). It is played with two dice on a board, on which is depicted a race-course with hurdles, water-jumps and other obstacles. The course is marked in 60 compartments by means of radii, and the game is won by the player whose horse makes the circuit in the fewest throws. Each player is provided with a marker, usually in the form of a jockey on horseback, which is moved forward after each throw to the space to which the number thrown entitles it. The popular deck or saloon game played on board ship with larger horses and a course on which obstacles are marked is a variation of this old pastime.

For steeplechasing in Great Britain *see* HORSE-RACING AND BREEDING, section *Steeplechasing and Hurdle-Racing.* Steeplechasing in America is treated below.

STEEPLECHASING in America began in Canada, where English officers, quartered at Montreal and Toronto, gave meetings. The Montreal hunt, founded in 1826, doubtless raced across country, and in 1850 a great steeplechase was held near the St. Pierre course. The race was for £100 over hurdles, stone walls, three double jumps, ditches and rasping fences. J. P. Dawes was a leading owner, and his Charlemagne, in 1882, carrying 175 lb.,

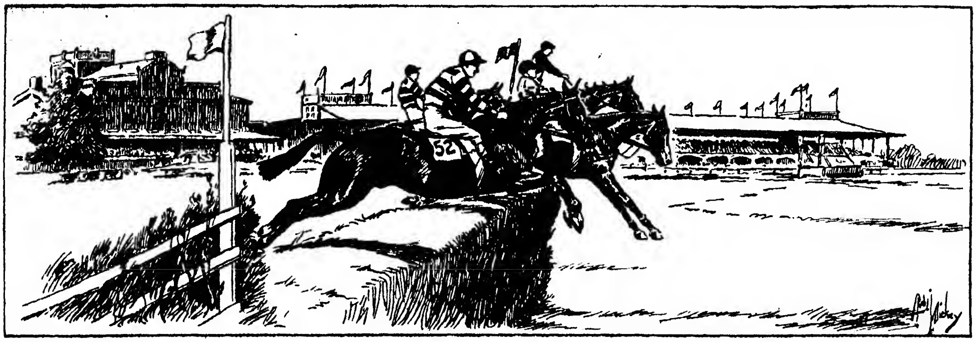
STEEPLECHASING IN THE UNITED STATES

1. The twenty-sixth running of the Challenge Cup at the Country Club, Brookline, Mass., under the auspices of the Eastern Horse Club
2. The Virginia Gold Cup, 1927, first offered in 1922. Won by Dum Dum, Mr. Donald Pearse up
3. Maryland Hunt Cup, 1926, first raced for in 1894. Won by Billy Barton, Mr. A. G. Ober, Jr. up—the winner leading
4. Meadow Brook Cup, 1927, first offered in 1833. Won by Billy Barton, Mr. Ober up



DRAWN BY ROBERT L. DICKEY

THE CAD (NO. 52) WINNING THE $10,000 CHAMPION STEEPLECHASE OF AMERICA, IN 1900, WITH OWNER, "MR. SMITH," UP

won at Mystic Park, Boston, and later at The Country Club, ridden by Strathey. The next year, carrying Baron von Zedlitz, he again won at Mystic Park, and the day following carried off The Country Club steeplechase handicap. Dawes' Rose, in 1882, won ten and finished second six times in 21 starts.

A steeplechase meeting was given in Toronto in 1843, the course being near Shepherd's Golden Lion, Yonge street. One race was won by Grasshopper, Black Douglas second, Aemilius Irving up. That fall a heavyweight steeplechase was won by Samuel P. Jarvis, Jr., riding Gaylad. Both Aemilius Irving and Samuel P. Jarvis were forebears of the well-known Canadian sportsman, Aemilius Jarvis. Canada boasts of the oldest steeplechase stake in America, "The Woodbine," won in 1882 by Rose, and in 1928 (the 44th running) by Wych Elm, owned by George W. Beardmore, master of the Toronto hunt.

W. S. Vosburgh writes that the first steeplechase in the States was at Paterson, N.J., June 7, 1865, a three-mile handicap, over 27 jumps, though the real beginning was an extra day's steeplechasing at Jerome Park in Nov. 1869. Vosburgh wrote articles for *The New York Sportsman* in 1880, telling of races won by Oysterman, Postguard, Trouble, Waller, Lobelia, Tammany, Diavolo, Major Pickett and Bourke Cockran, and of steeplechasing in New Orleans in 1871 and 1872.

The Driving Park, Chicago, in 1880, "had jumping races," and in 1884 the July stakes, a handicap, received 18 entries. Edward Corrigan owned a number of splendid jumpers and laid out a beautiful course at Hawthorne Park in 1891.

Hunt and Country Clubs.—Steeplechasing in America has always received its strongest backing from the hunt and country clubs, and the most valuable stake offered up to 1883 was given by the Rockaway hunt, with a guaranteed value of $5,000, which was won by Major Pickett. The Rosetree hunt raced across country about 1877. The Country club, Brookline, had 36 consecutive meetings from 1880. The Meadow Brook hunt cup was offered in 1883, and has been won by such well-known gentlemen riders as Stanley Mortimer, George Work, T. Hitchcock, "Billy" Hayes, "Mr. Smith," F. S. von Stade and others. Swan Latrobe gave a silver pitcher for the Genesee Valley point to point, which was won on Oct. 13, 1885, by Seward Cary's Patchen, Tom Cary up. "Mr. Smith" later won this race four times. The Maryland hunt cup, given by Ross Whistler, was first raced for in 1894. The Maryland grand national dates from 1900, and the race for My Lady Manor cup from 1908. In 1922 the Virginia gold cup was first offered, and earlier there was sport "Between the Flags" at Ivy City, where Harry Harwood was killed. At the Middleburg hunt, Piedmont Valley, and the Deep Run hunt at Richmond, the sport is beginning to flourish.

About Philadelphia there have been hunt races at the Radnor, White Marsh Valley club, Wissahickon Farms, and in other hunting countries, two of the leading patrons of sport being William Clothier and William Kerr, the latter's Algie and other cracks for years having made steeplechase history. Good sport has been provided by the Essex hunt since 1920 and elsewhere in New Jersey. The Bloomfield hunt held its first meeting in 1920 near Detroit, and the Onwentsia, near Chicago, the same year. Fine sport was shown by the Westchester-Biltmore Association at Bowman Park, Rye, in 1927, and in 1928 a meeting was held for the cavalry school at Ft. Riley, Kansas. In Massachusetts, the Willowdale cup has become a prominent feature, and in 1927 a splendid inaugural meeting was given by the Norfolk hunt. The Eastern horse club, founded by Augustus F. Goodwin and others, continuing the work of The Country Club in Massachusetts, has held three most successful meetings, and for a number of seasons the United Hunts Racing Association has held important meetings on Long Island. Private meetings were given by Joseph E. Widener at Elkins Park, Pa., and in 1927 and 1928 by John R. Macomber at his racing plant at Raceland, Framingham, Mass., and by Robert C. Winmill at Warrenton, Va.

The National Steeplechase Association.—In 1891, the National Steeplechase Association was founded by S. S. Howland, August Belmont and others, and was later merged into the National Steeplechase and Hunt Association, providing rules for racing which have been accepted by a number of the clubs, but their efforts have been small compared with what might have been accomplished. The chief work on behalf of sport has always been done by individual endeavour. In 1899 Robert Chamblet Hooper, Thomas Hitchcock and others founded the Champion Steeplechase of America and the Grand National, the former worth about $10,000 and the latter $8,000. The first Champion was won by James W. Colt's Van Ship, the second by Harry Worcester Smith's hunter The Cad, owner up, and the third by Self Protection, Harry Page up. "Billy" Hayes won the Grand National on Trillion, and in 1906 Thomas Hitchcock's Good and Plenty, carrying 170 lb., made a show of his field.

For a time without individual effort the sport deteriorated, except at the hunt clubs, until 1926 when Bayard Warren of Boston planned the rejuvenation of the Grand National, which was won at Belmont Park in 1927 by Jolly Roger, owned by Mrs. Payne Whitney, one of the strongest patrons of steeplechasing in America. Joseph E. Widener's colours, carried by Fairmount and others, have been prominent over the Park courses at Saratoga, Pimlico, Aqueduct and elsewhere, but to the Maryland Hunt Cup Association must be given the credit of upholding the true importance of sport "between the flags," for with their course of 4 m. over solid post and rails, averaging almost 5 ft., only first-rate horses and riders can conquer, and the list shows such great sportsmen as Jarvis Spencer, Jr., Redmond Stewart, A. Devereux, G. Mather, Arthur White, Raymond Belmont, J. N. Ewing, J. T. Bowen, A. B. Ober, F. A. Bonsal, Jr., and such horses as Princeton, Landslide, Sacandaga, Oracle, Burgoright, Billy Barton and Bon Master. Billy Barton has to be acknowledged as in a class by himself over timber courses, and his gallant showing, when

he finished second in the English Grand National of 1928, shows that steeplechase horses can be made in America

Vosburgh has so truly said. "Put up the fences and put up the weights Weight seldom breaks down a horse, and never has broken down one-tenth as many as speed has. By raising the weights we can have men in the saddle instead of boys, and by raising the fences we will have less falls and better races It will stop the speed and make the contest steeplechases where they are now little better than hurdle races."

See W S. Vosburgh, *Racing in America 1866–1921* (1922); *The Toronto Herald; Toronto Turf Club, Union and Niagara Races Race Cards; American Turf Register; The Turf, Field and Farm; The Spirit of the Times.* (H. W. SM.)

STEER, PAUL WILSON (1860–), English painter, was born at Birkenhead. He was trained first at the Gloucester school of art and afterwards in Paris at the Académie Julian, and in the École des Beaux Arts under Cabanel. After 1886, before which date he had shown three pictures at the Royal Academy, practically the whole of his work was seen in the exhibitions of the New English Art Club. In his early work he appears as an adherent of the French Impressionist movement, and as a teacher at the Slade School he exercised an important influence on the development of English contemporary art. His figure subjects and landscapes show great technical skill.

STEEVENS, GEORGE (1736–1800), English Shakespearian commentator, was born at Poplar on May 10, 1736, the son of an East India captain, afterwards a director of the company. He was educated at Eton and at King's College, Cambridge. Leaving the university (1756) without a degree, he settled in chambers in the Temple, removing later to a house on Hampstead Heath, where he collected a valuable library, rich in Elizabethan literature. He walked from Hampstead to London every morning before seven o'clock, discussed Shakespearian questions with his friend, Isaac Reed, and, after making his daily round of the booksellers' shops, returned to Hampstead He published in 1766 reprints of the quarto editions of Shakespeare's plays, entitled *Twenty of the Plays of Shakespeare* . . . Dr. Johnson suggested to him the preparation of a complete edition of Shakespeare The result, known as Johnson's and Steevens's edition, was *The Works of Shakespeare with the Corrections and Illustrations of Various Commentators* (10 vols, 1773), Johnson's contributions to which were very slight. This early attempt at a variorum edition was revised and reprinted in 1778, and further edited in 1785 by Isaac Reed; but in 1793 Steevens, who had asserted that he was now a "dowager-editor," was persuaded by his jealousy of Edmund Malone to prepare an edition of fifteen volumes He made somewhat reckless emendations, but the edition showed a wide knowledge of Elizabethan literature. He died at Hampstead on Jan. 22, 1800.

Steevens's Shakespeare was re-issued by Isaac Reed in 1803, in 21 volumes, with additional notes left by Steevens. This, which is known as the "first variorum" edition, was reprinted in 1813 Steevens's notes are also incorporated in the edition of 1821, begun by Edmund Malone and completed by James Boswell the younger

STEEVENS, GEORGE WARRINGTON (1869–1900), English journalist, was born at Sydenham, near London, on Dec. 10, 1869, and was educated at the City of London School and Balliol College, Oxford, of which he was a scholar In 1893 he was elected a fellow of Pembroke College, Oxford In September 1899 he went to South Africa and joined Sir George White's force in Natal as war-correspondent, being subsequently besieged in Ladysmith He died during the siege, of enteric fever, on Jan. 15, 1900 The best of his books were *With Kitchener to Khartoum* (1899), and *From Capetown to Ladysmith* (1900).

STEFANI, ALBERTO DE (1879–), Italian statesman, lectured on economics at Venice, Ferrara and Padua, and only entered politics in 1921, when he stood as an independent candidate for Verona. After he entered the Chamber he rapidly gravitated to the Fascist group. He was appointed minister of finance in Mussolini's cabinet (Oct. 28, 1922), and on the death of Professor Tangorra on Dec 21, combined the Treasury with this office. He was responsible for establishing equilibrium of the budget in 1924, in place of the large deficit of 1922–3 Before de Stefani retired in 1925 he was able to show a solid reduction in the national debt.

STEFANIE, BASSO NAEBOR or **CHUWAHA,** a lake of East Africa, lying in 37° E., between 4° 25′ and 5° N, and measuring some 40 m. by 15 It is the southernmost and lowest (1,880 ft.) of a series of lakes which lie in the north-easterly continuation of the great East African rift valley (*see* ABYSSINIA. *River and Lake System*) The character of the lake, which has no outlet, varies greatly according to the amount of water brought down by its principal feeder, the Dulei, which enters at its north end, being there a rapid stream 50 yd wide and 3½ ft deep

Lake Stefanie was discovered by Count Samuel Teleki in 1881, and has since, with others of the series, been explored by Donaldson Smith, V. Bottego, M. S. Welby, Oscar Neumann, Arnold Hodson and others. An agreement of 1907 with Great Britain recognized the lake as within the Abyssinian empire.

See *Geographical Journal* (Sept. 1896, Sept. and Dec. 1900, Sept. 1901, Oct 1902, July 1922); L von Höhnel, *Discovery of Lakes Rudolf and Stefanie* (1894); L. Vannutelli and C. Citerni, *L'Omo* (Milan, 1899); British War Office map, Africa, 1 2,000,000 (1924).

STEFANSSON, VILHJALMUR (1879–), Arctic explorer, was born on Nov. 3, 1879, at Arnes, Manitoba, Canada, of Icelandic parents He graduated from the University of Iowa and later studied theology and anthropology for three years at Harvard university After two archaeological voyages to Iceland in 1904 and 1905 he turned to Arctic research and had by 1928 spent altogether 10 winters and 13 summers in scientific work north of the polar circle. In 1906–07 he was ethnologist of the Leffingwell-Mikkelsen expedition on the north coast of Alaska and at the mouth of Mackenzie river; in 1908–12 he commanded an expedition on which he discovered certain Eskimo groups and visited others who had not seen a white man for half a century From 1913 to 1918 he commanded an arctic expedition under the auspices of the Canadian Government. During more than five years continuously north of the Arctic Circle (the longest Arctic expedition on record) he explored vast regions north of Canada and Alaska, sometimes sledging for months over moving ice, accompanied by two or three companions and living exclusively by hunting He discovered between 1915 and 1917 the islands now known as Borden, Brock, Meighen and Lougheed, and several smaller islands. In 1918 his then second in command, Storker Storkerson, taking charge while Stefannson was ill with typhoid fever, explored by sledge, with four companions, the Beaufort sea north of Alaska. They were absent from shore about eight months, during six of which they were encamped, and lived by hunting, on a floe more than five miles in diameter while it drifted with them 450m over a previously unexplored ocean from 1m to 3m deep. They found an abundance of seals everywhere, had therefore plenty of food and fuel, suffered no hardships, and reported on their return that they felt sure they could have spent several years on this floe safely This confirmed the conclusions of all the previous sledge journeys of the expedition over the moving ocean ice—that seal life, and therefore probably other water life, does not necessarily decrease, as was previously believed, farther north in the Arctic. Stefansson has laid great stress on the economic value of the Arctic regions, chiefly as meat-supplying countries through the cultivation of the domestic reindeer and the domestication of the ovibos or musk-ox. In 1924 Stefansson visited the Macdonnell ranges of central Australia.

His principal publications are: *My Life with the Eskimo* (1913); *Anthropological Report* (1914); *The Friendly Arctic* (1921); *The Northward Course of Empire* (1922); *Hunters of the Great North* (1922); *The Adventure of Wrangel Island* (1926); *The Standardization of Error* (1927).

STEFFANI, AGOSTINO (1653–1728), Italian ecclesiastic, diplomatist and musical composer, was born at Castelfranco on July 25, 1653. At a very early age he was admitted as a chorister at St Mark's, Venice. Count Tattenbach took him in 1667 to Munich, where his education was completed at the expense of Ferdinand Maria, elector of Bavaria, who gave him a court appointment. He was sent in 1673 to study in Rome, where Ercole Bernabei was his master, and among other works he composed six motets, the original manuscripts of which are now in the Fitz-

william Museum at Cambridge. On his return to Munich in 1674 he published his first work, *Psalmodia vespertina,* a part of which was reprinted in Martini's *Saggio di contrappunto* in 1674. In 1675 he was appointed court organist. The date when he was ordained priest, with the title of Abbate of Lepsing, is not precisely known. Steffani's first opera, *Marco Aurelio,* which was written for the carnival and produced at Munich in 1681, was followed by other works now lost. In 1688 he became Kapellmeister at the court of Hanover, where he made many friends. He wrote for the opening of the new opera house in 1689, an opera called *Enrico il Leone,* which was produced with extraordinary splendour. For the same theatre he composed *La Lotta d'Ercole con Achilleo* in 1689, *La Superbia d'Alessandro* in 1690, *Orlando generoso* in 1691, *Le Rivali concordi* in 1692, *La Libertà contenta* in 1693, *I Trionfi del fato* and *I Baccanali* in 1695, and *Briseide* in 1696. Elevation of Ernest Augustus to the electorate in 1692 led to difficulties with the various German courts; Steffani was sent round as an envoy in 1696 and as a result received from Innocent XI. the bishopric of Spiga for his services in securing privileges for Hanoverian Catholics. In 1698 he was sent as ambassador to Brussels, and after the death of Ernest Augustus in the same year he entered the service of the elector palatine, John William, at Düsseldorf, where he held the offices of privy councillor and protonotary of the Holy See.

Steffani did not accompany the elector George to England; but in 1724 the Academy of Ancient Musick in London elected him its honorary president for life; and in return for the compliment he sent the association a magnificent *Stabat Mater,* for six voices and orchestra, and three fine madrigals. The manuscripts of these are still in existence, and the British Museum possesses a very fine *Confitebor,* for three voices and orchestra, of about the same period. All these compositions are very much in advance of the age in which they were written; and in his operas Steffani shows a remarkable appreciation of the demands of the stage. Notable too are his beautiful chamber-duets, which, like those of his contemporary Carlo Maria Clari (1669–1745), are chiefly written in the form of cantatas for two voices, accompanied by a figured bass. The British Museum (Add. MSS. 5,055 *seq.*) possesses more than a hundred of these compositions, some of which were published at Munich in 1679. Steffani visited Italy for the last time in 1727. He died at Frankfurt on Feb. 12, 1728.

STEFFEN, ALBERT, Swiss novelist and dramatist, was born at Murgental (Canton Aargau) on Dec. 10, 1884. He is an imaginative, spiritual, mystical and idealistic writer, showing little of the concrete and disciplined methods that are so characteristically Swiss. His nearest spiritual kinsman is, perhaps, Dostoievski (*q.v.*); he has also something in common with Carl Spitteler (*q.v.*). His special quality reveals itself in his novels, such as *Ott, Alois, und Werelsche* (1907), *Die Bestimmung der Roheit* (1912), *Der Rechte Liebhaber des Schicksals* (1916), *Sibylla Mariana* (1917) and *Die Erneuerung des Bundes* (new ed., 1925); in his shorter stories, such as *Die Heilige mit dem Fische* (1919) and *Verhängnisse* (1927); in his plays, such as *Das Viergetier* (1924) and *Der Chef des Generalstabs* (1927); and in his essays, such as *Die Krisis im Leben des Künstlers* (1922), *Der Künstler zwischen Westen and Osten* (1925) and *Begegnungen mit Rudolf Steiner* (1926).

STEFFENS, HENRIK (1773–1845), German philosopher, of Norwegian extraction, was born on May 2, 1773, at Stavanger. He studied in Germany, and began to lecture at Copenhagen in 1802. His lectures were appreciated by Grundtvig and Oehlenschläger, but the authorities regarded them with disfavour, and Steffens removed to Germany, where he fought in the Napoleonic wars on the German side. He was professor of physics at Breslau (1811–32) and at Berlin (1832–45). He died in Berlin on Feb. 13, 1845. Steffens was the friend and adherent of Schelling and Schleiermacher. His profound knowledge of physics modified the speculations of Schelling. His chief works were *Beiträge zur innern Naturgeschichte der Erde* (1801); *Grundzüge der philos. Naturwissenschaft* (1806); *Anthropologie* (1824). He also wrote novels and poetry and an autobiography, *Was ich erlebte,* and after his death there was published *Nachgelassene Schriften* (1846).

See M. Tietzen, *Zur Erinnerung an Steffens* (1871); Petersen, *Henrik Steffens* (1884); W. Dilthey, *Leben Schleiermachers* (1870).

STEGANOPODES or **PELICANIFORMES,** an order of birds characterized by the fact that the hind toe is united to the second toe by a web. Most species are gregarious and live on fishes. The order includes the pelicans, cormorants, gannets, snake-birds, frigate-birds and tropic-birds (*q.v.*).

STEGOCEPHALIA, a class of extinct Amphibia (*q.v.*).

STEGOSAURUS, the name given to a Jurassic group of reptiles (*q.v.*). The name (plated lizard) refers to the armour of heavy bony plates on the back. These animals, which belonged to the class Dinosauria, were vegetarian. The plates of bone projected in two rows along the back, and the tail was armed with spikes. The head was small. It is surmised from the fact that the hind legs are much longer than the fore legs that the stegosaurs were descended from bipedal forms which were compelled to re-adopt a quadrupedal gait to enable them to support the weight of their bony armour. They reached a length of 30ft.

STEIN, SIR AUREL (1862–), British archaeologist, was born at Budapest on Nov. 26, 1862. Educated at Budapest and Dresden and at the Universities of Vienna and Tübingen, he went to England for further study and then to India, where he became principal of the Oriental college, Lahore, and registrar of the Punjab university in 1888. He was appointed in 1899 to the Indian Education Service, and for the next two years carried out archaeological explorations for the Indian Government in Chinese Turkistan. In 1906–08 he made further explorations in central Asia and western China, receiving the gold medal of the Royal Geographical Society. From 1910 he was superintendent of the Indian Archaeological Survey, and in 1913–16 carried out explorations in Persia and central Asia, described by him in *The Geographical Journal* (1916). He was created K.C.I.E. in 1912. In 1926 he continued his explorations on the Northwest Frontier and identified the site of Aornus, thus correcting Abbott's view. His other works include: *Chronicle of Kings of Kashmir* (1900); *Ancient Khotan* (1907); *Ruins of Desert Cathay* (1912); *Serindia* (5 vols., 1921); *The Thousand Buddhas* (1921); and articles in the present edition of the *Encyclopædia Britannica.*

STEIN, CHARLOTTE VON (1742–1827), the friend of Goethe, was born at Weimar on the 25th of December 1742, the eldest daughter of the Hofmarschall (master of the ceremonies) von Schardt. She became in her sixteenth year lady-in-waiting to the duchess Anna Amalia, the accomplished mother of Duke Karl August of Saxe-Weimar. In 1764 she married Freiherr Friedrich von Stein, master of the horse to the duke, and seven children were the issue of the union.

Goethe's *Briefe on Frau von Stein aus den Jahren 1776–1820* were edited by A. Schöll (3 vols., 1848–1851; 2nd ed. by W. Fielitz, 1883–1885; 3rd ed. by J. Wahle, 1900). *See* H. Düntzer, *Charlotte von Stein* (2 vols., 1874); id., *Charlotte von Stein und Corona Schröter* (1876); G. H. Calvert, *Charlotte von Stein* (Boston and New York, 1877); and A. Sauer, *Frauenbilder aus der Blütezeit der deutschen Literatur* (1885); W. Bode, *Charlotte von Stein* (1910).

STEIN, HEINRICH FRIEDRICH KARL, BARON VOM UND ZUM (1757–1831), German statesman, was born at the family estate near Nassau, on Oct. 26, 1757, the ninth child of Karl Philipp, Freiherr vom Stein. He studied law at Göttingen, Wetzlar, Regensburg and Vienna, and settled in Berlin in 1780. There he entered the Prussian service.

After holding various diplomatic and other appointments he became (1787) Kammerdirektor, *i.e.*, director of the board of war and domains for the king's possessions west of the river Weser; and in 1796 he was appointed supreme president of all the Westphalian chambers dealing with the commerce and mines of those Prussian lands. Among the benefits of his administration was the canalization of the river Ruhr, which became an important outlet for the coal of that region. He also improved the navigation of the Weser, and kept up well the main roads committed to his care. On June 8 1793 he married the countess Wilhelmine von Wallmoden-Gimborn, daughter of a natural son of King George II. of Great Britain.

Stein's early training, together with the sternly practical bent of his own nature, made him completely impervious to the enthusiasm which the French Revolution had aroused in many minds in Germany He disliked its methods as an interruption to the orderly development of peoples. Nevertheless he carefully noted the new sources of national strength which its reforms called forth in France. Under the untoward circumstances which followed the Peace of Basel Stein in 1804 took office at Berlin as minister of state for trade. He protested against the effects of the Gallophil policy of the chief minister, Haugwitz, and the evil influences which clogged the administration. Little, however, came of Stein's protests, though they were urged with his usual incisiveness and energy. Prussian policy continued to progress on the path which led to the disaster at Jena (Oct. 14, 1806)

The king then offered to Stein the portfolio for foreign affairs, which he declined, because he desired to see Hardenberg take that office and effect, with his own help, the necessary administrative changes The king refused to accept Hardenberg, and, greatly irritated by Stein's unusually outspoken letters, dismissed him altogether, adding that he was "a refractory, insolent, obstinate and disobedient official." Stein now spent in retirement the months during which Napoleon completed the ruin of Prussia; but he saw Hardenberg called to office in April 1807 and important reforms effected in the cabinet system During the negotiations at Tilsit, Napoleon refused to act with Hardenberg, who thereupon retired. Strange to say, the French emperor at that time suggested Stein as a possible successor, and on Oct. 4, 1807, Frederick William called Stein to office with very wide powers

Stein's strong convictions led him to press on drastic reforms in a way which could not otherwise have been followed First came the Edict of Emancipation, issued at Memel on Oct. 9, 1807, which abolished the institution of serfdom throughout Prussia from Oct. 8, 1810 All distinctions affecting the tenure of land (noble land, peasants' land, etc) were also swept away, and the principle of free trade in land was established forthwith. The same famous edict also abrogated all class distinctions respecting occupations and callings of any and every kind, thus striking another blow at the caste system which had been so rigorous in Prussia. Stein's next step was to strengthen the cabinet by wise changes and he also furthered the progress of the military reorganization which is connected more especially with the name of Scharnhorst (*q v*) Stein's efforts were directed more towards civil affairs, and in this sphere he was able to issue a measure of municipal reform (Nov 19, 1808) which granted local self-government on enlightened and practical lines to all Prussian towns

In August 1808 the French agents, who swarmed throughout the land, had seized one of his letters, in which he spoke of his hope that Germany would soon be ready for a national rising like that of Spain On Sept 10 Napoleon gave orders that Stein's property in the new kingdom of Westphalia should be confiscated, and he likewise put pressure on Frederick William to dismiss him The king evaded compliance; but the French emperor, on entering Madrid in triumph, declared (December 16) *le nommé Stein* to be an enemy of France and the Confederation of the Rhine; and ordered the confiscation of all his property in the Confederation. Stein saw that his life was in danger and fled from Berlin (Jan. 5, 1809) to Bohemia

For three years he lived in the Austrian Empire, generally at Brünn; but in May 1812 he received an invitation from the emperor Alexander I to visit St Petersburg, seeing that Austria was certain to range herself on the side of France in the forthcoming Franco-Russian War At the crisis of that struggle Stein may have been one of the influences which kept the tsar determined never to treat with Napoleon When the miserable remains of the Grand Army reeled back into Prussia at the close of the year, Stein urged the Russian emperor to liberate Europe

Events now brought Stein rapidly to the front. On Dec. 30, 1812, the Prussian general Yorck signed at Tauroggen a convention with the Russian general Diebitsch for neutralization of the Prussian corps at and near Tilsit, and for the free passage of the Russians through that part of the king's dominions The tsar thereupon requested Stein to act as provisional administrator of the provinces of East and West Prussia. In that capacity he convened an assembly of representatives of the local estates, which Feb. 5, 1813, ordered the establishment of a militia (*Landwehr*), a militia reserve and a final levy (*Landsturm*). He took part in the drafting of a Russo-Prussian convention (March 19, 1813) respecting the administration of the districts which should be delivered from French occupation. During the varying phases of the campaign of 1813 Stein continued to urge the need of war *à outrance* against Napoleon The Allies conferred on Stein the important duties of superintending the administration of the liberated territories. After the battle of Leipzig (Oct. 16–19, 1813) Stein entered the city.

He now desired to see Germany reconstituted as a nation, in a union which should be at once strong for purposes of defence and founded on constitutional principles His statesmanlike projects were foiled, partly by the short-sightedness of German rulers and statesmen, but also by the craft with which Metternich gained the alliance of the rulers of south and central Germany for the Austrian empire. During the Congress of Vienna Stein pressed in vain for an effective union of the German people. Austria and the secondary German states resisted all proposals in this direction, and Stein blamed the Prussian chancellor Hardenberg for an indefiniteness of purpose which probably resulted from the same defect in Frederick William of Prussia. Stein shared in the desire of all Prussian statesmen at that time to have Saxony wholly absorbed in their kingdom. In that, as in other matters, he was disappointed.

Stein passed into retirement after the Congress of Vienna, and saw with pain and disgust the postponement of the representative system of government which Frederick William had promised to Prussia in May 1815. His chief interest was in the study of history, and in 1818–1820 he worked hard to establish the society for the encouragement of historical research and the publication of the *Monumenta Germaniae historica*, of which his biographer, Pertz, became director. Stein died on June 29, 1831

Possibly there has been a tendency to magnify the achievements of Stein. Research has shown that the credit for originating his reforms must be shared with Heinrich Theodor von Schon and many others.[1] The king himself rendered large services to this cause, but Stein's enlightenment, insight and almost superhuman energy ensured the triumph of these principles.

STEINER, JAKOB (1796–1863), Swiss mathematician, was born on March 18, 1796, at the village of Utzendorf (Berne). At eighteen he became a pupil of Heinrich Pestalozzi, and afterwards studied at Heidelberg. Thence he went to Berlin and became one of the chief contributors to Crelle's *Journal* founded in 1826 In 1834 a new chair of geometry was founded for him. This he occupied till his death on April 1, 1863.

Steiner was one of the great developers of synthetic geometry

[1]Thus Schön's memorandum on the abolition of serfdom was the basis of the law of emancipation; and Stein's *Politisches Testament* was also based on a draft by Schön Schön was born in 1773, entered the Prussian civil service in 1793, and subsequently held various high ministerial appointments. He was made castellan (*Burggraf*) of Marienburg on his retirement in 1842, and died in 1856. The share claimed by him in Stein's reforms has been the subject of some controversy

In his *Systematische Entwickelung der Abhängigkeit geometrischer Gestalten von einander* he introduces the geometrical forms (the row, flat pencil, etc.), and establishes between their elements a one-one correspondence, or, as he calls it, makes them projective.

See C. F. Geiser's pamphlet, *Zur Erinnerung an J. Steiner* (Zürich, 1874).

STEINER, RUDOLF (1861–1925), German philosopher, was born on Feb. 27, 1861, at Kraljevic, Austria, the son of a small railway employee. From 1890 to 1897 he worked in Weimar at the "Goethe-Schiller Archive," editing Goethe's works on natural history. In 1902 the German section of the theosophic association was founded and Steiner was called upon to become its spiritual leader. As such he developed for some years an astonishing activity as regards lectures and writings, but then became opposed to theosophy altogether, and was therefore excluded from the theosophical centre under English leadership. Steiner now developed his own teaching in a series of writings. He called this "anthroposophy," *i.e.*, wisdom of humanity: mankind is regarded as the centre of all perceptions of this "spiritual science," and an attempt is made to deduce the nature of the world from the nature of humanity. In 1913 the Anthroposophical society was formed to further spiritual research on Steiner's principles. In order to try his educational and political views in practice, Steiner founded the Waldorf School, near Stuttgart, and the "free high school for spiritual science" known as the "Goetheanum" at Dornach near Basle, which was burnt a few years later. All Steiner's works are published by the *Philosophisch-anthroposophischer-Verlag*, Berlin, and *Der kommende Tag*, Stuttgart. He died at Dornach on May 30, 1925.

His chief works include: *Goethe, als Vater einer neuen Aesthetik* (1888), Eng. ed. in preparation; *Die Philosophie der Freiheit* (1894), Eng. trans. ed. H. Collinson, *The Philosophy of Freedom* (1916); *Friedrich Nietzsche* (1895); *Goethes Weltanschauung* (1897); *Theosophie* (1904), Eng. trans. by E. D. S., *Theosophy* (1910); *Haeckel, die Welträtsel und die Theosophie* (1905), Eng. trans. *Haeckel, The Riddles of the Universe;* and *Theosophy in Three Essays on Haeckel, and Karma* (1914); *Wie erlangt man Erkenntnisse der höhern Welten* (1909); Eng. ed. trans. Clifford Bax, 2 vol., *The Way of Initiation* and *Initiation and its Results* (1909–10); *Die Aufgabe der Geisteswissenschaft und deren Bau in Dornach* (1916); Eng. ed. trans. A. M. Wilson, *The Mission of Spiritual Science and of its Building at Dornach, Switzerland* (1917); *Die Kernpunkte der sozialen Frage* (1919); Eng. ed. *The Threefold State—The True Aspect of the Social Question* (1920); *In Ausführung der Dreigliederung des Sozialen Organismus* (1920), Eng. trans. in *The Threefold Commonwealth* (1921 *seq.*).

See E. Boldt, *Von Luther bis Steiner* (1921), Eng. trans. (1923); F. Rittelmeyer, *Von Lebenswerk R. Steiners* (1921); G. Kaufmann, *Fruits of Anthroposophy; an Introduction to the Work of Dr. R. Steiner* (1922).

STEINLE, EDUARD (1810–1886), Austrian painter, was born in Vienna on July 2, 1810. In 1828 he joined the "Nazarene" groups, started by Overbeck and Cornelius in Rome. It was not, however, a congenial atmosphere for one of his romantic temperament, and in 1833 he returned to Vienna, moving in 1838 to Frankfurt, where he was professor of historical painting at the Staedel institute from 1850, and where he died on Sept. 19, 1886. He had the freshness and poetical fancy of the Viennese, and his best work is found in such legendary subjects as "Loreley" (Shack gallery, Munich), "The Violinist," and the illustrations to fairy-tales by Brentano and others.

See O. Berggruen, *Die Galerie Shack* (*Graphische Künste*, iv. 3, 4); C. v. Wurzbach, *E. Steinle, ein Madonnenmaler unserer Zeit* (Vienna, 1879).

STEINMETZ, CHARLES PROTEUS (1865–1923), American electrical engineer, born at Breslau, Germany, April 9, 1865. He was educated at Breslau, Zürich and Berlin, specializing in mathematics, electrical engineering and chemistry. His activities as a Socialist led him into difficulties with the authorities, and, after a short sojourn in other countries, he emigrated in 1889 to the United States and found work with the Osterheid and Eickemeyer factory at Yonkers. In 1893 when that factory was absorbed by the General Electric Co., Schenectady, he was given an appointment as consulting engineer. His knowledge won him speedy promotion and he soon became recognized as one of the outstanding electrical geniuses of America. After 1902 he served also as professor of electrical engineering at Union College. Steinmetz regarded his three greatest contributions to electrical science to be: (1) his investigations on magnetism resulting in his discovery of the law of hysteresis, which enabled losses of electric power due to magnetism to be accurately forecast before starting the construction of motors, generators, transformers, and other electrical apparatus employing iron; (2) the development of his symbolic method of calculating alternating-current phenomena which simplified an extremely complicated field, understood by few, so that the average engineer could work with alternating-current, an accomplishment which was largely responsible for the rapid progress made in the commercial introduction of alternating-current apparatus; (3) his investigation of lightning phenomena which resulted in his theory of electrical transients, and opened the way for his development of lightning arresters to protect high-power transmission lines. Though primarily a mathematical genius and a student of theory, he had some 200 patents to his credit, including improvements on generators, motors, transformers, in electro-chemical operations, and the invention of the induction regulator, the method of phase transformation and the metallic electrode arc lamp. Besides a large number of scientific papers he was the author of a number of standard text-books. He died at Schenectady, N.Y., Oct. 26, 1923.

See J. W. Hammond, *Charles Proteus Steinmetz, a biography* (1924), and J. N. Leonard, "Steinmetz, Jove of Science," in *World's Work*, vol. 53, nos. 2, 3 and 4 (1929).

STEINMETZ, KARL FRIEDRICH VON (1796–1877), Prussian general field-marshal, was born at Eisenach on Dec. 27, 1796. At the outbreak of the War of Liberation he and his elder brother made their way through the French posts to Breslau, where they at once received commissions. The brothers took part in the hardest fighting of the campaign of 1813, the elder being killed at Leipzig and the younger being more than once wounded. After the peace he entered Paris but once, fearing to infringe upon the ten ducats that he saved monthly from his pay to send to his mother. His character and physique were strengthened by his Spartan way of life, but his temper suffered. From 1820 to 1824 he studied at the General War Academy.

Steinmetz was promoted general of infantry in 1864, and led the V. Corps to the war against Austria in 1866. This was the chance of his lifetime. His skilful and resolute leadership was displayed in his three battles, won on three successive days, of Nachod, Skalitz and Schweinschädel (*see* SEVEN WEEKS' WAR).

At the outbreak of the war of 1870 Steinmetz was appointed to command one of the three armies assembled on the Rhine, the others being led by Prince Frederick Charles and the crown prince. Serious differences arose between Steinmetz and Prince Frederick Charles. After the battle of Gravelotte he was relieved of the command of the I. Army and was sent home as governor-general of the V. and VI. Army Corps districts. In April 1871 he was retired at his own request, but his great services were not forgotten, and he was promoted general field-marshal. He died at Bad Landeck on Aug. 2, 1877.

STELE, a non-structural pillar or vertical slab of stone, metal or marble, usually set up for votive or commemorative purposes, sometimes decorated with bas-reliefs and bearing inscriptions, and generally terminated with a cresting enriched in classic examples with the anthemion plant with a small pediment. Stelae are common in Chinese tombs and temples, and usually these consist of an inscribed panel crowned by the dragon, and supported on the back of a great turtle.

STELLAR DISTRIBUTION: *see* STAR.

STELLAR EVOLUTION. A star cannot shine unchanged for ever. It must have a life-history, an evolution of some sort. For a star is not a mere lump of inert matter; it is actively radiating energy—heat and light—into the unsounded depths of space, and at a tremendous rate. This energy, according to our present understanding of nature, can be no new creation—it must have come from some storehouse within the star. Such a store of energy cannot be inexhaustible; unless it is in some way replenished from without, the star must ultimately cease to shine.

Though a star's life is thus probably of limited duration, it is doubtless so long that the span of human history is too short to

afford hope of detecting even a trace of change by direct observation. Yet, as a visitor to a forest might, in a few moments, see trees in all stages of youth, maturity and decay, we may reasonably expect to find among the stars in the heavens examples of every stage of their evolution The problem becomes, therefore, that of picking out, among the various types of stars known to observation, those which, on some reasonable physical theory, should represent the earlier and later stages of the process Such a theory must depend on some knowledge, or at least some hypothesis, concerning the nature of the store of energy which the stars are expending, and hence the problems of the source of stellar energy and the course of stellar evolution are inseparable.

The Contraction Theory—Of the known stores of energy, calculable by familiar physical principles, which a star possesses the greatest is the gravitational potential energy, arising from the mutual attraction of its parts. These attractive forces tend to compress the star If they were not balanced by the internal pressure of the gases of the interior the star would contract, the gravitational forces would do work, and a corresponding amount of potential energy would be liberated, appearing as heat of compression in the gas. If, at a given instant, the internal pressures just balanced those due to gravity, nevertheless, as the star lost heat by radiation from its surface, the interior would tend to cool and the gas-pressure to diminish Contraction would then begin and continue till enough heat had been produced to raise the pressure and restore the balance. The evolution of a star, on this conception, would be a gradual shrinkage—part of the heat liberated by transformation of the gravitational potential energy maintaining the internal equilibrium and the rest keeping up the radiation.

This first rational theory of stellar evolution owes its origin to Hermann von Helmholtz. What proportion of the liberated energy is stored inside the star, and how much remains available to keep it shining, can be calculated from the known laws of gases Much of the internal energy is the *kinetic energy* of motion of the atoms of the gas, to which it owes its high temperature. Part is energy of *ionization* The collisions between the atoms are so violent that the outer electrons which normally belong to their structure are detached and fly about independently. To remove them against the electrical attraction of the residue of the atoms demands a large expenditure of energy which would be released again if the gas should cool and the collisions become less violent Finally, the *radiation* imprisoned within the star, flying from atom to atom and gradually working its way out to the surface, carries an amount of energy which, especially in the stars of greatest mass, is a considerable fraction of the whole

All told, it appears that more than half of the energy liberated by contraction, and sometimes a good deal more, must be stored inside the star in these three forms; but that, under actual conditions, a surplus will be available to meet the loss by radiation

Lane's Law—As the star contracts its internal temperature rises In the simplest case, when the laws of a "perfect" gas hold good and the density at all points within the star is increased in the same proportion by the contraction, it can easily be proved that the temperatures at corresponding points vary inversely as the radius of the star (Lane's Law, first stated by J. Homer Lane in 1870), *thus* this law should indicate the order of magnitude of the change in more complex cases.

Limiting Density—Such a process of contraction and rise in temperature obviously must have a limit. Sooner or later the atoms of the gas must get so close together that there is little room for further compression Under such conditions the rise of internal temperature would slow up and then cease and the star would ultimately cool down, behaving more like a liquid than a gaseous mass. Until within a few years it was supposed that this change would begin to happen when the mean density of the star was less than that of water, and a theory of stellar evolution, proposed originally by Sir Norman Lockyer and reconstructed by H N. Russell, held the field for some time But in 1924 A S Eddington pointed out that the ionized atoms throughout the main mass of a star, being stripped of all their outer electrons, must occupy far less space than under ordinary conditions, so that serious departures from the simple gas-laws should not be anticipated till their density had become many thousands of times greater than that of water. The range of possible contraction of a star must therefore be very great.

This conclusion of theory is fully confirmed by observation. It is now possible to calculate the diameters of hundreds of stars, and the densities of a great number The latter range from less than a thousandth part that of ordinary air in the case of great red stars like Antares to more than a thousand times that of platinum in the case of the companion of Sirius and the other "white dwarfs" Stars of the former sort appear to be "young"—in the sense that they have most of their visible life still before them—and those of the latter class to be "old." The sun, whose mean density is 1.4 times that of water, comes not far from the middle of the sequence.

Age of a Star.—When the length of a star's life comes to be considered, the contraction theory meets with grave difficulties The amount of gravitational energy which would have been released by the contraction of the sun, for example, from an indefinitely great size to its present dimensions is readily calculable, and is found to amount to as much as would supply the present rate of radiation from the surface for 46,000,000 years More than half this must still be stored inside the sun and twenty million years' supply at most can be counted available for radiation This was pointed out long ago by Lord Kelvin

But there is now abundant evidence from radioactive data that the oldest sedimentary rocks recognized by geologists are of the order of a thousand million years old (probably somewhat more), and that, during all this interval, the temperature of the earth's surface has been closely the same as at present The sun has therefore, during geological time, dissipated in radiation more than 50 times as much energy as it could have derived from gravitational sources, and yet has remained of about the same brightness all the time. For the giant red stars of low density the case is even stronger The gravitational energy available for a star's past radiation is proportional to M^2/R (M being the star's mass and R its radius). For Antares, for example, for which R is 480 times as great as for the sun, and M probably only 30 or 40 times as great, the available energy is some three times as great as for the sun. Antares radiates heat at 10,000 times the sun's rate, so that its whole past history, if gravitational energy only were available, would occupy only 6,000 years

Sub-Atomic Energy—Such arguments have convinced practically all workers in the field that the sun, and the stars in general, must draw to maintain their radiation upon some vast supply of energy whose very existence was previously unsuspected. The problem of stellar evolution thus enters upon a new and difficult stage, for, since this "unknown source" of energy has never been tapped in our laboratories, it is hard to find out about it Atomic theory, in its present state of development, is not able to tell us very much, but what it does tell is striking The only storehouses in the known universe *small* enough to hold so much energy are the tiny nuclei of the atoms, or perhaps the still smaller protons and electrons of which they are composed For particles at greater distances, such as those at the periphery of an atom, the forces are not great enough to do so much work The main source of stellar energy appears therefore to be of "sub-atomic" nature. In this conclusion, again, all workers agree.

Loss of Mass—A second conclusion follows from the theory of relativity According to this all energy possesses mass, and mass and energy are, to some degree at least, interconvertible, in a definitely known ratio To m grams of matter correspond mc^2 ergs of energy (where c is the velocity of light). Translated into more familiar units, this means that it is as legitimate to speak of a pound of heat as of a pound of iron But a pound of heat is a very large amount, measured by ordinary standards; it would suffice to raise 20 million tons of rock to a temperature of 1,500° C. and melt it into incandescent lava. The amounts of heat involved in all ordinary thermal changes are therefore of such small mass that it is still usually permissible to treat heat as "imponderable"; but when it comes to the radiation of the stars the case is different. The sun radiates energy into space at the rate

of $3{\cdot}8 \times 10^{33}$ ergs per second—a number too great to be directly appreciable even by the physicist. Expressed as mass, this means that the sun is getting rid of 4,200,000 *tons of heat every second.* No other mode of statement comes so near to conveying to human apprehension the tremendous activity of a star.

The sun's mass must actually be diminishing at this portentous rate, which might raise fears of its disappearance. But its present mass is so great ($1{\cdot}98 \times 10^{33}$ grams) that the existing radiation would use up only a millionth part of it in 15 million years, and the consumption of a moderate fraction would give a life long enough to meet the wildest demands of geology.

Process of Transformation.—What the process of transformation is by which mass disappears and energy is liberated—pound for pound—can only be conjectured. The spontaneous disintegration of heavy complex atoms, as in the case of radio-activity, liberates a great amount of energy. The formation of heavier atoms out of hydrogen would furnish still more; for such an atom weighs about 0·8 per cent. less than the corresponding number of hydrogen atoms, which contain protons and electrons enough to make it. The difference may best be attributed to liberation of energy in the reaction of formation. The conversion of a mass equal to the sun's from hydrogen to iron, for example, would liberate heat enough to maintain the present solar radiation for 120,000 million years. Finally, it may be that a proton and an electron, under certain rare conditions, may annihilate one another—the electrical charges being neutralized, the mass disappearing, and the energy escaping and being converted into heat in the surrounding gas. If the whole mass of the sun were expendable in this fashion, and should be steadily consumed at the present rate, it would shine for 15,000,000,000,000 (15×10^{12}) years before it vanished.

The existence of some transformable material, and the maintenance of radiation by loss of mass, are now generally accepted as inevitable deductions from observed facts. Whether the total change of mass during a star's history is a large or small fraction of the whole is less easy to settle. According to the answer which we give our views of the life-history of a star will be different.

Stellar Luminosity.— Though the manner in which heat is generated within a star remains obscure, the manner in which it gets out of a star is now clearly understood. Radiation in the interior is very intense. Light is streaming about in all directions, but going only a short distance before it is absorbed by the hot gas and re-emitted. On the average, this results in a flow of energy from the hotter to the cooler parts, at a rate which is greater the more rapid the fall in temperature per mile, and less the greater the opacity of the gas to radiation. Modern physics makes it possible to determine pretty closely the laws which govern the emission of radiation and its absorption by the gas, and their changes with the temperature, density, and composition of the material. A detailed theory of the luminosity of the stars has thus been developed by Eddington, which gives results in admirable accordance with the observed facts. The conclusions which concern the present problem are that the amount of heat which leaks out from the interior of a star and escapes from its surface, depends very little upon a star's diameter but very greatly upon its mass. If a star of given mass contracts, the temperature inside rises and the temperature gradient becomes steeper. The opacity remains nearly constant, but the area of the surface diminishes. The effects of these changes almost balance one another, so that the total radiation of the star is changed but little. The amount which escapes per square mile, however, increases steadily, so that, as the star contracts, its surface must become hotter and its light whiter.

Whether the total radiation increases or diminishes as the radius grows smaller depends on the finer points of the theory. Eddington, after a careful investigation, concludes that it increases slightly; but the possibility that it remains constant, or even diminishes a little, cannot be excluded from consideration.

For a star of the same size, but smaller mass, the temperature gradient is less and the opacity greater, so that much less heat escapes from the surface. These conclusions apply strictly only to stars which are built upon the same law of internal distribution of density, but it is not hard to prove—following Eddington—that for a wide range of laws of internal density, of the type that appear at all plausible, the calculated total radiation will differ but little.

If, then, the proportion of expendable matter within a star is small it will remain of nearly the same brightness all through its evolution, until it becomes so dense that calculations based on the simple laws of gases are no longer applicable. But if a considerable portion of its mass is lost by radiation it will be fainter in its old age than in its youth.

Stability.—A new difficulty now arises. If the rate at which heat escapes from a star of given mass is so nearly fixed, whatever its size, what will happen to a star in which the rate of income of heat from sub-atomic sources is out of balance with this fixed outgo? If the income is too small, it is evident that the star will have to draw on its gravitational store and will contract; if the income exceeds the outgo, the process will be reversed and the star will expand, storing up the excess energy by means of the work done against gravitation.

Whether the energy-account will remain unbalanced after these changes depends on the way in which the rate of income from sub-atomic sources changes as the star contracts, and the pressure and temperature in its interior increase. If these changes increase the rate of generation of energy, then a star of deficient income, as it contracts, will find its income gaining on its expenditure and will approach a state of equilibrium. Should it overshoot this and contract too far the income would exceed the outgo and expansion would be forced, tending again to restore the equilibrium.

In this case, and in general, when income of heat gains, relative to outgo, as the star contracts, the equilibrium will be stable. The rate at which equilibrium of this sort is approached is slow, being comparable with that of a "Kelvin contraction," so that the adjustment will require tens of thousands of years even for the most rarefied giant stars, and tens of millions for stars like the sun. In the opposite case, when the outgo gains relative to the income, equilibrium, if it existed, would be unstable, the smallest deviation tending to increase indefinitely.

If a star's expenditure of heat increases as it contracts, stability demands that the rate of sub-atomic change shall increase more rapidly; if, on the other hand, the expenditure diminishes, stability may be possible with a fixed income, such as radioactivity might furnish.

Overstability.—Too rapid an increase in income, however, leads to other dangers. Any external disturbance affecting a star may set it "pulsating"—alternately expanding and contracting, under the influence of its own gravitation. Eddington has shown that the leakage of heat from one part of the star to another should act like friction to damp out the pulsation. But, if heat is generated most rapidly when the star has contracted to its smallest size, this gives a succession of well-timed impulses, which may overcome the damping effect, and, if great enough, cause the pulsation to increase to a large amplitude. This condition, called by Eddington "overstability," will (in the case studied by him) occur if, when the star contracts, the percentage increase of the rate of heat production is more than about twice that of the temperature. There remains, however, a considerable range in which stability of both kinds is assured.

Appeal to Observation.—To find out more about the laws of release of sub-atomic energy we must go to the stars themselves, and in the present state of knowledge our answers must be tentative, showing that a certain assumed law may account for the observed phenomena rather than *proving* that such a process actually happens. The conclusions previously stated appear to be well founded; those which follow may be greatly changed by future investigation. Our guides must be the observable properties of the stars, and, in particular, their luminosities and temperatures. We might add "their masses," if it were not that observation fully supports Eddington's conclusion that the stars of a given luminosity all have nearly the same mass.

Colour-Brightness Diagrams.—These relations may best be exhibited by means of "colour-brightness" diagrams, in which the brightness of a star (its absolute magnitude) is plotted as vertical co-ordinate, and its colour (which is intimately related to its surface temperature and its spectral type) as horizontal co-ordinate. When such a diagram is made from all reliable

observational data, it is found that the points representing the stars are far from being distributed at random

The majority of points fall into a definite sequence—the "main series"—ranging from bright, hot, white stars like those in Orion's Belt, through those of moderate brightness like the sun, to faint, cool, red ones like Barnard's star of large proper motion, as is indicated by the points 1, 2, 3, 4, 5 in fig. 1 There

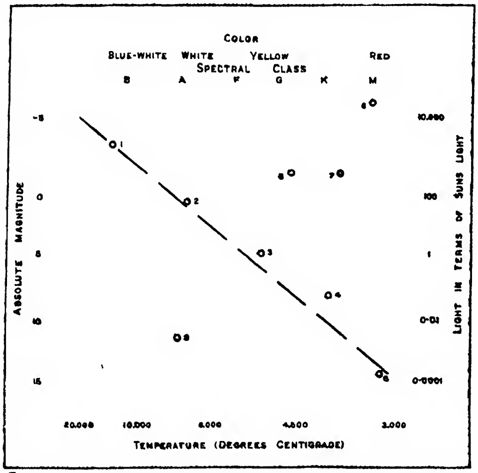

FIG 1—RELATIONS BETWEEN THE COLOUR AND BRIGHTNESS OF STARS (1) Stars of Orion's Belt, (2) Sirius, (3) The Sun, (4) 61 Cygni, (5) Barnard's Star, (6) Antares, (7) Arcturus, (8) Capella, (9) Companion of Sirius

are also many bright red and yellow "giant" stars like Antares, Arcturus or Capella (6, 7 and 8), and probably many more faint white dwarfs like the Companion of Sirius (9), which fall quite outside the main series

The Main Series.—Since most of the known stars belong to the main series, we may begin by trying to account for this. According to Eddington's calculations the central temperatures of the stars along this series are nearly the same, and not far from 40,000,000°C. Suppose now that there is a process of liberation of sub-atomic energy within the stars, such that its rate is low at temperatures of a few millions of degrees, increases steadily, and, for a central temperature of 40,000,000°, becomes equal to the rate of loss for a star of corresponding mass. If now we have a star of great mass and low density it will be bright, red, and of large diameter, and represented by a point such as A_1 in fig 2. Its central temperature will be low, it will contract, drawing on its gravitational energy, and the point on the diagram will move to A_2 and A_3. But as it approaches the dotted line corresponding to the central temperature 40,000,000°, heat from sub-atomic sources will be turned on—so to speak—and the star will come into a steady state at A_0 and remain at it, drawing on sub-atomic energy, for a very long time. Similarly, stars of smaller mass and low initial density will pass through the stages represented by B_1–B_2B_0 and C_1–C_0. If we imagine a star of moderate mass and very high density at the start, it would have too great an income of sub-atomic energy and expand through the stages D_1, D_2, D_0 and come to rest on the same line. If no other sub-atomic process were at work within the stars it is clear that, however they were started, they would all be found, after a few millions of years, along the main series A_0, B_0, D_0, C_0. The strong, actual concentration of stars along this series suggests that some such process of energy liberation may actually take place. The points actually lie not in a line, but along a strip of some width; but this is easily explained. If the percentage of active material in a star were lower than that at first considered the central temperature would have to be higher to cause income and outgo to balance, and we should have points along a line like A′C′. It is freely admitted that no theoretical reason can be given, in our present ignorance of the laws governing the structure of atomic nuclei, and still more those which determine the existence of protons and electrons, why liberation of energy should occur at this particular temperature, and be so adjusted as to be much more rapid in the more massive stars, where the central density is relatively low, than in those of small mass, where it is high. But no conclusive reasons against it can be given either, and the facts speak for themselves.

Giants and White Dwarfs—This temperature does not account for the existence of the red giants, or the white dwarfs. They appear to demand the assumption of a second process, independent of the first, which liberates energy at a rate also increasing with the temperature, but very much greater when the density is low than when it is high, so that, for stars of different mass, it would make income equal to outgo for points along such a line as shown in fig. 3

If this process alone were in operation, stars of various masses would follow courses represented by A_1 A_0, B_1 B_2 B_3, etc., and concentration would ensue along a sequence including the red giants and the white dwarfs. With both processes at work at once the result is shown in fig. 4 A star of large mass, as it contracts, will turn on the second process first, and settle down as a red giant, at A_0. If, however, the material thus transformable were absent, or soon exhausted, it would proceed farther to the left and become a white giant at A_0'. Less massive stars would settle down at B_0 and C_0, the latter drawing on both sub-atomic processes at once. Still smaller masses would be stabilized as yellow dwarfs at D_0 and red dwarfs at E_0, unless material of the first sort were absent, when the latter would become a white dwarf at E_0'.

Star Clusters.—Suppose now that a great quantity of matter were broken up into masses of various sizes which started independent careers as stars After a few millions, or tens of millions, of years, the points representing them would be found along the broken line A_0, B_0, C_0, D_0, E_0 (fig 4)—all stages from red giants to red dwarfs being represented among stars of the same age in years. With the lapse of time the bright giant stars, which expend energy very rapidly, might exhaust the material of the second kind, and move over to the line A'_0C_0 or near it, while the relatively sluggish dwarf stars changed very little. This distribution of color and brightness would result at once if material of the second kind were absent. Now precisely these two situations are found among star clusters. (*See* R. J. Trumpler, *Publications of the Astronomical Society of the Pacific*, vol. xxxvii. pp. 307–318, 1925) In some there is a group of bright red stars, near A_0, and others on the main series, while in others the branch A_0' C_0 is represented.

Double Stars.—Similarly, among the double stars, a pair with components of large mass would settle down at first like A_0, B_0—the brighter star being the redder one—a pair of small mass at D_0, E_0, with the fainter star the redder. The great majority of the double stars fall into one or other of these two classes. A few pairs have components of very different brightness, but the same colour (B_0, D_0), and in some, like A_0, C_0, the brighter component is a very hot star, of spectral class B All these phenomena are immediately accounted for by the theory.

Course of Evolution.—The question of the history of an individual star is not yet answered. If the expendable fraction of the star's whole mass is small, it must remain of nearly the same brightness all through its history (fig. 5). A star of great mass will linger as a red giant A_2, A_3, till it has exhausted one store of energy, losing a little brightness as it consumes its mass, then pass rapidly to A_4 where it draws on the other store, finally exhausting it and shrinking beyond our ken One of moderate mass will spend practically its whole life between B_2 and B_3, as a star of moderate temperature (spectral class F) and moderate brightness. One of small mass, after a long career as a red dwarf at C_2, C_3, may become a white dwarf at C_4. If, on the other hand, most of the mass is expendable, a single star may pass through almost the whole known sequence of stellar types. Beginning at A_1 (fig. 6),

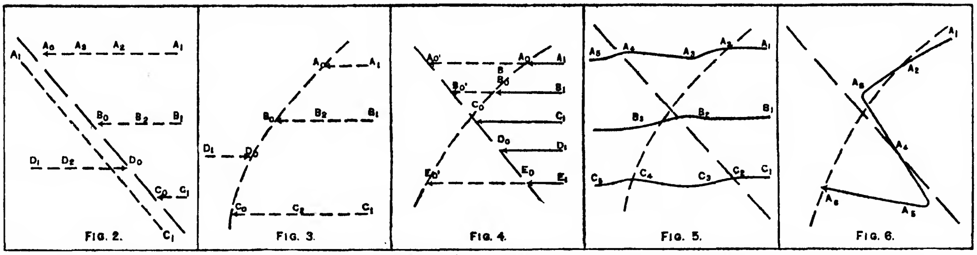

FIG. 2.—APPROACH OF STARS TO EQUILIBRIUM. PROCESS I. FIG. 3.—APPROACH OF STARS TO EQUILIBRIUM. PROCESS II. FIG. 4.—APPROACH OF STARS TO EQUILIBRIUM. BOTH PROCESSES. FIG. 5.—EVOLUTION OF STARS. SMALL LOSS OF MASS. FIG. 6.—EVOLUTION OF STARS. GREAT LOSS OF MASS

perhaps as a long period variable (the coolest and least dense of all known stars), it may become a yellow giant like Capella (A_2) and a white star like Sirius (A_3). At this point, before all the material of the second sort is exhausted, that of the first kind may begin to be consumed. Till it is gone the star must remain on the main series, passing through a stage resembling the sun (A_4), and one like 61 Cygni (A_5). Ultimately, after all the material of the first sort is exhausted, the star may become a white dwarf at A_6, fed by the unexpended store of the second kind. Many other life-histories, with a less extensive set of changes, are possible with different initial amounts of the two transformable substances.

The question cannot yet be regarded as settled. Indeed, the whole evolutionary scheme here sketched, which follows the lines laid down by Russell in 1927—is of a highly tentative nature. The two processes of energy liberation which are postulated are frankly invented *ad hoc,* and the best that can be claimed for them is that they account for most of the facts. The advance of atomic physics may replace them by something far more firmly grounded, and very different.

It may be said in conclusion that a very different evolutionary scheme has recently been put forward by Jeans, who regards the rate of liberation of energy as independent of the temperature, like radioactivity, and believes that the stars are unstable when the simple gas-laws are obeyed, and concentrated in certain regions on the diagram because, under the corresponding physical conditions of partial ionization, the behaviour of the gas departs widely from the ordinary laws, resembling that of a liquid. That such departures from the gas-laws should occur at the observed densities he has not yet shown, nor is it easy to see how they can happen. But the suggestion illustrates that there are probably many possibilities still unexplored.

(H. N. R.)

STELLENBOSCH, a town 31 m. E. of Cape Town by rail, and, next to the latter, the oldest town in the province; 33° 54′ S., 18° 48′ E.; altitude 364 feet. It was founded in 1681, and named after the governor, Simon van der Stel, and his wife, whose maiden name was Bosch. The town is built in a valley, and its streets are lined with oak trees, and open channels of water. Many of the houses with heavy, thatched gables, date from the 17th century. The Dutch church in the market square is also thatched. Stellenbosch is the centre of a rich fruit and wine producing area, and the headquarters of the Cape branch of the Dutch Reformed church, with a Dutch theological seminary. There are several high schools in the town, a normal training college and a self-contained university with a strong Dutch bias. The population in 1921 included 3,695 whites, 122 natives, 33 Asiatics and 3,455 mixed and other coloured.

STEM, in popular language the stalk of a plant or trunk of a tree. In botany a stem may be defined as an axis bearing leaves. The stem with its leaves is known as the shoot. Structurally it differs from a root in having no cap (*root cap*) over the growing-point and in terminating in a bud. Under the term *caulome* (stem-structure) are included all those parts of a plant morphologically equivalent in bearing leaves. The stem generally ascends, seeking air and light, and has therefore been termed the *ascending axis.* Stems have usually considerable firmness and solidity, but sometimes they are weak, and either lie prostrate on the ground, thus becoming *procumbent,* or climb on plants and rocks by means of rootlets, like the ivy, being then called *scandent,* or twist round other plants in a spiral manner like woodbine, when they are *twining.* Twining plants turn either anti-clockwise, as the French bean, convolvulus, dodder and gourd; or clockwise, as honeysuckle, twining polygonum, hop and black bryony. In other cases climbing plants are supported by tendrils, which may be modified stems, as in vine, bryony, passion-flower, or by the tendril-like leaf-stalks, as in clematis and *Tropaeolum.* In warm climates twining plants (*lianas*) often form thick woody stems, while in temperate regions they are generally herbaceous. Some stems are developed more in diameter than in height, and present a peculiar shortened and thickened aspect, as *Testudinaria* or tortoise-plant, cyclamen, *Melocactus, Echinocactus* and other Cactaceae; while in many orchids the stem assumes an oval or rounded form, and is called a *pseudobulb.*

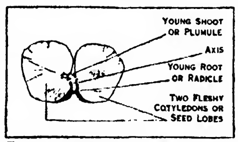

FIG. 1.—EMBRYO OF BEAN WITH COTYLEDONS SEPARATED

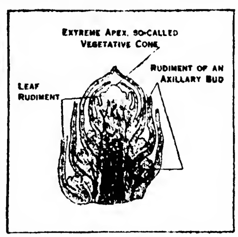
Names are given to plants according to the nature and duration of their stems. *Herbs,* or *herbaceous* plants, have stems which die down annually. In some of them the whole plant perishes after flowering; in others, the lower part of the stem forming the *crown of the root* remains, bearing buds from which the stem arises next season. In *biennial* herbs the whole plant perishes after two years, while in *perennial* herbs the crown is capable of producing stems for many years, or new annual products are repeatedly added many times, if not indefinitely, to the old stems. The short permanent stem of herbaceous plants is covered partially or completely by the soil, so as to protect the buds. Plants producing permanent woody stems are called *trees* and *shrubs.* The latter produce branches from or near the ground, while the former have conspicuous trunks. Shrubby plants of small stature are called *under-shrubs* or *bushes.* The limits between these different kinds of stem are not always well defined; and there are some plants occupying an intermediate position between shrubs and trees, sometimes called *arborescent shrubs.*



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (FISCHER)

FIG. 2.—APEX OF SHOOT OF PHANEROGAMIC PLANT STEM

The stem is not always conspicuous. Plants with a distinct stem are *caulescent;* those in which it is inconspicuous are *acaulescent,* as the primrose, cowslip and dandelion. A similar term is given

in ordinary language to plants whose stems are buried in the soil, such as cyclamen or sowbread. Some plants are truly stemless, and consist only of expansions of cellular tissue representing stem and leaf, called a *thallus,* and hence are denominated *Thallophytes.* (*See* ALGAE, FUNGI.)

Development of Stem.—The first rudiment of the young shoot of the embryo appears from the seed after the radicle (young root) has protruded It is termed the *plumule,* and differs from the radicle in the absence of a root-cap and in its tendency to ascend The apical growing portion constitutes the terminal bud of the plant, and by its development the stem increases in height; projections appear at regular intervals, which are the rudimentary leaves, and in addition there is a provision for the production of lateral buds, which develop into lateral shoots more or less resembling the parent stem, and by these the branching of the plant is determined These buds are found in the *axil* of previously formed leaves, or, in other words, in the angle formed between the stem and leaf. They are hence called *axillary.* They are produced like the leaves from the outer portion of the stem, and at first consist entirely of cellular tissue, but in the progress of growth vascular bundles are formed in them continuous with those of the stem, and ultimately branches are produced, which in every respect resemble the axis whence the buds first sprang The place of origin of the leaf is called a *node;* the intervals between nodes are called *internodes* The stem, although it has a tendency to rise upwards when first developed, in many instances becomes prostrate, and either lies along the ground partially covered by the soil, or runs completely underneath its surface, giving off roots from one side and buds from the other. Some stems are therefore subterranean, and are distinguished from roots by the provision made for regular leaf-buds

FIG. 3 —LEAF-BUD OF SYCAMORE

Growth and Bud Formation.—Growth in length of the stem is due to elongation of the internodes; the zone of most rapid growth is at some distance below the apex; below this the rate of growth gradually diminishes until the portion is reached where growth in length no longer takes place. In some cases, as in the stems of grasses, growth in length persists for a longer time in a small region at the base of the internodes; this is known as *intercalary* growth In the dwarf or short shoots, such as those of the larch, the internodes do not elongate and the leaves remain close together. Lateral buds give rise to *branches,* from which others, called *branchlets* or *twigs,* arise. The terminal bud, after producing leaves, sometimes dies at the end of one season, and the whole plant, as in annuals, perishes, or part of the axis is persistent, and remains for two or more years, each of the leaves before its decay producing a bud in its axil This bud continues the growth in spring In ordinary trees, in which there is provision made for the formation of numerous lateral buds, any injury done to a few branches is easily repaired; but in palms, which only form terminal buds, and have no provision for a lateral formation of them, destruction of the terminal bud may kill the tree. In the trees of temperate and cold climates the buds which are developed during one season lie dormant during the winter, ready to open in the spring They are generally protected by external modified leaves in the form of *scales,* which frequently exhibit a firmer and coarser texture than the leaves themselves They serve a temporary purpose, and usually fall off sooner or later, after the leaves are expanded. The bud is often protected by a coating of resinous matter, as in the horse-chestnut and balsam poplar, or by a thick downy covering, as in the willow.

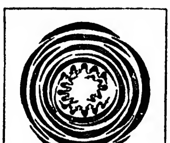


FIG. 4 —TRANSVERSE SECTION OF SYCAMORE LEAF-BUD

In plants of warm climates the buds are often formed by the ordinary leaves without any protecting appendages; such buds are called *naked.* A bud may be removed in a young state from one plant and grafted upon another by the process of *budding,* so as to continue to form its different parts, and it may even be made to grow in the soil, in some instances, immediately after removal. In some trees of warm climates, as papaw, palms and tree-ferns, growth by terminal buds is well seen

When the terminal bud is injured or arrested in its growth the elongation of the main axis stops, and the lateral branches often acquire increased activity By continually cutting off the terminal buds or branches, a woody plant is made to assume a bushy appearance, and thus *pollard* trees are produced. The peculiar bird-nest appearance often presented by the branches of the common birch depends on an arrestment in the terminal buds, a shortening of the internodes, and a consequent clustering or fasciculation of the twigs (*See* GALLS)

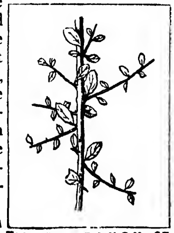

FIG 5 —BRANCH OF SLOE

Branching.—The mode in which branches come off from the stems gives rise to various forms of trees, as pyramidal, spreading or weeping—the angles being more or less acute or obtuse In the Italian poplar and cypress the branches are erect, forming acute angles with the upper part of the stem; in the oak and cedar they are spreading or patent, forming nearly a right angle, in the weeping ash and elm they come off at an obtuse angle, while in the weeping willow and birch they are pendulous from their flexibility The comparative length of the upper and under branches also gives rise to differences in the contour of trees, as seen in the conical form of spruce, and the umbrella-like form of the Italian or stone pine (*Pinus Pinea*).

Branches are sometimes long and slender, and run along the ground, producing buds with roots and leaves at their extremity. This is seen in the *runner* of the strawberry In the houseleek (*Sempervivum*) there is a similar prostrate branch of a shorter and thicker nature, known as an *offset,* producing a bud at its extremity capable of independent existence In many instances the branch decays, and the young plant assumes a separate existence. Gardeners propagate plants by the process of *layering,* which consists in bending a twig, fixing the central part of it into the ground, and, after the production of roots, cutting off its connection with the parent A *stolon* differs from these in being a branch which curves towards the ground, and, on reaching a moist spot, takes root and forms an upright stem, and ultimately a separate plant This is a sort of natural layering, and the plant producing such branches is called *stoloniferous.* In the rose and mint a subterranean branch arises from the stem, which runs horizontally to a certain extent, and ultimately sends up an aerial stem, which becomes an independent plant Such branches are denominated *suckers,* and the gardener cuts the connection between the sucker and the parent stem, to propagate these plants

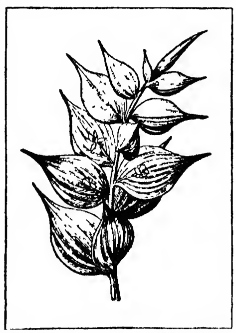

FIG. 6 —TWIG OF BUTCHER'S BROOM

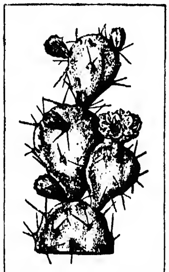
In the case of asparagus and other plants which have a perennial stem below ground, subterranean buds are annually produced which appear above ground as shoots or branches covered with scales at first, and ultimately with true leaves These branches are herbaceous and perish annually, while the true stem remains below ground ready to send up fresh shoots next season In bananas and plaintains the apparent aerial stem is a shoot sent up by an underground stem, and perishes after fruiting. Branches are sometimes arrested in their development, and, in place of forming leaves, become transformed into *spines* or *thorns,* as in the hawthorn. Plants which have spines in a wild state, as the apple

and pear, often lose them when cultivated, in consequence of their being changed into branches; in some cases, as in the sloe (*Prunus spinosa*), a branch bears leaves at its lower portion, and terminates in a spine. In some cases branches become flat and leaf-like, taking the place in the plant economy of the leaves, which are reduced to small scales or spines, as in butcher's broom; branches showing this modification are termed cladodes or phylloclades. In Cactaceae (e.g., *Opuntia*, prickly pear) and fleshy euphorbias, where the leaves are reduced to spines, the fleshy stems become green and perform the functions of leaves; they also serve as water reservoirs for the plants, which are natives of very dry countries.



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (FISCHER)

FIG. 7.—OPUNTIA MONACANTHIA

Rhizomes, Corms and Bulbs.—The typical form of stems is rounded. They are sometimes compressed or flattened laterally, while at other times they are angular. Various terms are applied to the forms of stems, as *cylindrical* or *terete*, *quadrangular* or *square*, *jointed* or *articulated*, etc. The following are some of the more important modifications of stems: The crown of the root is a shortened stem, often partially underground, which remains in some plants after the leaves, branches and flower-stalks have withered. In this case the internodes are very short, and the nodes are crowded together, so that the plant appears to be stemless. It is seen in perennial plants, the leaves of which die down to the ground annually. A *rhizome* or *rootstock* is a horizontal stem usually sending out numerous roots and leaf-buds from its upper surface. It occurs in ferns, iris, *Hedychium*, *Acorus* or sweet flag, ginger, waterlily, many species of *Carex*, rushes, anemone, etc. The leaves are reduced to scales and by their presence, the absence of a root-cap and the presence of a bud at the apex, a rhizome can be distinguished from a root.

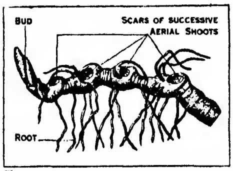


FIG. 8.—RHIZOME OF POLYGONATUM MULTIFLORUM

A rhizome such as occurs in Solomon's seal is not a single stem, *i.e.*, the product of a single bud, but is composed of portions of successive axes, the aerial parts of which have died off, leaving their scars. A rhizome sometimes assumes an erect form, as in *Scabiosa succisa*, in which the so-called *praemorse* root is in reality a rhizome, with the lower end decaying. The erect rhizome of *Cicuta virosa* (water-hemlock) shows hollow internodes, separated by partitions. In the coral-root orchid *Corallorhiza*, which grows in soil rich in humus, no roots at all are developed, the coral-like branching rhizome acting as the absorbing organ. A *tuber* is a thickened stem or branch produced by the reduction of the distance between the nodes and the swelling of the internodes, as in the potato. The eyes of the potato are leaf-buds. Tubers are sometimes aerial, occupying the place of branches. The ordinary herbaceous stem of the potato, when cut into slips and planted, sends off branches from its base, which assume the form of tubers. Tubers frequently store up a quantity of starch, as in *Maranta arundinacea*, whence West Indian arrow-root is derived.

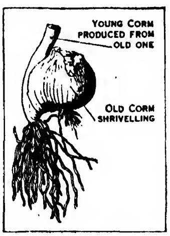

FIG. 9.—CORM OF MEADOW SAFFRON

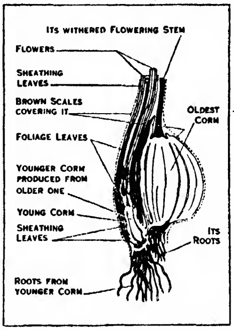
Another form of thickened underground stem is the *corm*, as seen in the autumn crocus (*Colchicum*), gladiolus, etc. Structurally it is composed of a solid more or less rounded axis covered by a layer of thin membranous scales. A corm is only of one year's duration, giving off buds annually in the form of young corms. In autumn the young corm gives origin to leaves, the lower of which form sheaths round the corm and flower stalk, the upper remaining very small; and in the axil of the uppermost leaves the flowering-stem develops and bears the flowers. Meanwhile in the axil of one of the middle leaves on the corm, a bud—the rudiment of a new corm—appears. The flowering-stem dies down, and the young corm from which it arose enlarges greatly during the winter at the expense of its parent corm, which thus becomes shrivelled. In spring the leaves produced on it, which were merely rudiments in autumn, appear above ground as conspicuous large leaves. At the end of spring these leaves die down, the bases of the lower ones alone remaining, and constituting thin brown scales around the corm. Meanwhile, the young bud-corm in the axil of the middle leaf grows rapidly at the expense of its parent corm, but it does not attain a great size. In autumn it produces new leaves, which remain small, but from the axil of the two upper the flowering stem rises up and bears flowers; whilst in the axil of one of its middle leaves a new bud-corm appears, which will the following autumn produce young leaves, flowering stem, and a new bud-corm, and thus the cycle goes on.



FROM SACHS, "TEXT BOOK OF BOTANY" (CLARENDON PRESS)

FIG. 10.—CORMS OF COLCHICUM AUTUMNALE

The *bulb* is another form of underground stem or bud. The axis in this case is much shortened, and the internodes are hardly developed. The bases of the leaves rising from the stem are quite close together, and become succulent and enclose the axis. In the lily the thick and narrow scales are arranged separately in rows, and the bulb is called *scaly;* while in the leek, onion and tulip the scales are broad, and enclose each other in a concentric manner, the outer ones being thin and membranous, and the bulb is *tunicated.* In the axils of these fleshy scales new lateral shoots arise, forming new bulbs. The lateral buds sometimes remain attached to the axis, and produce flowering stems, so that apparently the same bulb continues to flower for many years, as in the hyacinth and tulip; at other times the young bulbs are detached, and form separate plants.

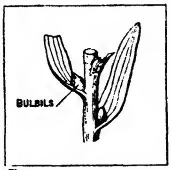


FIG. 11.—STEM OF BULBIFEROUS LILY

In the axil of the leaves of *Lilium bulbiferum, Dentaria bulbifera,* and some other plants, small conical or rounded bodies are produced, called *bulbils* or *bulblets.* They resemble bulbs in their aspect, and consist of a small number of thickened scales enclosing a growing-point. These scales are frequently united closely together, so as to form a solid mass. The scales in bulbs vary in number. In *Gagea* there is only one scale; in the tulip and *Fritillaria imperialis* they vary from two to five; while in lilies and hyacinths there are a great number of scales.

Adventitious Shoots.—Adventitious shoots are those which arise elsewhere than in the normal predetermined place, as from old stems or roots. Such shoots are frequent on the roots of elm, poplar, plum and other fruit-trees. Occasionally adventitious buds are produced on the edges of leaves, as in *Bryophyllum calycinum, Malaxis paludosa,* and various species of *Asplenium,* and on the surface of leaves, as in *Ornithogalum thyrsoideum.* These are capable of forming independent plants. Similar buds are also made to appear on the leaves of *Begonia, Gesnera, Gloxinia* and *Achimenes,* by wounding various parts of them, and placing them in moist soil; a method pursued by gardeners in their propagation.

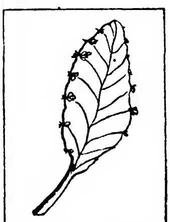

FIG. 12.—LEAF OF BRYOPHYLLUM CALYCINUM

STENCIL, a thin plate or sheet of metal, leather, paper or other material cut or pierced with a pattern or design; this is laid upon a surface and colour or ink is brushed or rubbed over it, thus leaving the ground colour of the surface imprinted with the design or pattern cut out In ceramics the stencil is produced by coating the biscuit with a preparation which prevents the transfer-paper or enamelling from adhering to the surface at those parts where the original colour of the biscuit is to be preserved

STENDAL, a town in the province of Prussian Saxony, situated on the Uchte, 70 m. W of Berlin on the main line of railway to Hanover and at the junction of lines to Bremen, Magdeburg and Wittenberge. Pop (1925) 29,827 Stendal was founded in 1151 by Albert the Bear, on the site of a Wendish settlement, and soon afterwards acquired a municipal charter Becoming capital of the Altmark, it rose to a considerable degree of prosperity, in part recently restored to it by its railway connections. The original Wends were gradually fused with the later Saxons

STENDHAL (1783–1842) the pseudonym of HENRI-MARIE BEYLE, who borrowed the name from a small German town, the birthplace of Winckelmann, and who chose for his epitaph, *Qui giace, Arrigo Beyle Milanese; visse, scrisse, amò* He was one of the most original and distinguished of French essayists and novelists. He was born at Grenoble on Jan 23, 1783

From Nov 1796 to 1799, he attended the Ecole Centrale at Grenoble, where he was brilliantly successful Here he was initiated into mathematics and accurate thinking. He arrived in Paris soon after the 18th Brumaire to study for the Ecole Polytechnique, but he soon gave up this scheme. Pierre Daru, the future *grand administrateur* of the empire, was a relation and his patron, and obtained a post for him in the War Office; later, in 1799, he sent him to Italy which became the chosen country of this cosmopolitan. He lived at Novara and Milan, in the autumn of 1800 became a sub-lieutenant, but resigned in 1802 and lived in Paris, where he frequented the *salons* and the theatres. After attempting business in Marseilles, in Aug 1805, out of infatuation for an actress, he became a deputy to the *commissaire des guerres* (1806). He then lived for two years beyond the Rhine in Brunswick. He asked vainly for a post in Spain, was appointed auditor to the *Conseil d'Etat* in 1810, took part in the Russian campaign and became *intendant* at Sagan in 1813. He had received his baptism of fire in the Alps; he had heard the cannon at Marengo, and seen close at hand the horrors of war at the burning of Ebersberg, Smolensk and Moscow. During the tragic hours at the Beresina, he presented himself, freshly shaved, to Daru, who by this recognized in him an *homme de coeur* After the empire fell, having lost all hope of being appointed a prefect, he went to live in Italy (1814–21); he spent six years in Milan, where he became acquainted with Byron, Madame de Staël, Silvio Pellico, Manzoni and Monti, whom he calls "the greatest living poet "

In 1814, he published in Paris *les Lettres écrites de Vienne en Autriche sur le célèbre compositeur, Joseph Haydn, suivies d'une vie de Mozart et de considérations sur Métastase et l'état présent de la musique en France et en Italie, par L C A Bombet* Herein he pillaged Carpani, Schlichtegroll, Winckler and Cramer His plagiarisms would have brought him less reproach if he had acknowledged them more generously. *L'histoire de la peinture en Italie, par M B A.A.* (Beyle, *ancien auditeur*), appeared in 1817. Stendhal explains and animates the works of the abbé Lanzi and Vasari, he adds trivial or profound reflections to his borrowings from Lavater and Bossi In *Rome, Naples et Florence* (1817), Stendhal supplemented his recollections with abundant documentary research; the work contains a wealth of fine, ingenious and vivid impressions on life, music, Italian patriotism, and on the charm of the delicious life he was enjoying In this respect, this work seems to contain the matter of and to be a commentary on *La Chartreuse de Parme.*

In 1821 Stendhal was suspected of *carbonarisme* and espionage, and had to return to Paris Exiled from his terrestrial paradise in Italy, he visited the houses of La Pasta, de Tracy and Delécluze, and made friends of Mérimée and Jacquemont A brilliant and paradoxical talker, he both pleased and scandalized. He attempted to reconcile his dandyism with his poverty He travelled in England in 1821 and 1826 and sent regular accounts and articles to the various English reviews, and to French journals

He continued to publish literary hack-work: the amusing and anecdotal *Vie de Rossini* (1823) in which his dilettante spirit demanded from music a sentimental pleasure and poetic reverie. *Les Promenades dans Rome* (1829) was a partial success. The "cicerone of intelligence and taste" was not content with anecdotes; he described manners, customs and the art of the *"chasse au bonheur"* in Italy; and the guide may again be seen in the account of the landscapes and monuments which enchanted the author. In 1838 appeared *Les Mémoires d'un Touriste* Stendhal had travelled extensively through France, either alone or in company with Mérimée, who instructed him in the Gothic. In addition to *choses vues,* the description of his native province, the Dauphiné, and the fair of Beaucaire, the work contains many stories clipped from journals or taken from the impressions of others But it is saved by its vivid and feeling style, and by its "precious nothings." Stendhal also wrote some more original works *De l'amour* (1822) constitutes under the guise of a psychological and documented analysis, a study and a preface for his novels, physiology is mingled with psychology. In it is also found a curious and original theory of "crystallization," a symbolic picture of the birth and growth of love.

Stendhal's first novel was an interesting study of this "crystallization," *Armance ou quelques scènes d'un salon de Paris en 1827* (1827). This was followed by a novel dealing with love and ambition—*Le Rouge et le Noir* (1830) In reading the *Gazette des Tribunaux,* which he cynically called "the golden book of French energy in the 19th century," Stendhal had noticed a tragic incident. The son of a farrier of the Dauphiné, a former seminarist, had been guillotined at Grenoble on Feb 23, 1828, for having shot and wounded a lady whom he loved. On this scandalous material the novelist constructed his story and even wove in some personal confessions, for his Julien Sorel sometimes resembles the author. The interest of this novel is found in the energetic spirit of his characters, full of intense and unscrupulous life, in the dramatic adventures, traits of character and passion noted with precision and clearness, and in its psychological analysis

Stendhal had already shown himself to be a pamphleteer It was by a real pamphlet that he took his position in the Romantic battle, when he published in 1823 *Racine et Shakespeare,* which was re-published in 1825 with more vigour and more mordancy than ever. This work was impregnated with the Italian Romanticism of Manzoni, Visconti and Berchet. Stendhal attempted to free the theatre from the "unities" of place and time He condemned Alexandrine verse and recommended a national tragedy which would be modern, even topical, and by preference liberal These ideas were not all new, but the tone and the accent were completely personal. Stendhal had protested against the industrialism of Saint Simon in his witty work *D'un nouveau complot contre les industriels* (1825)

Shortly after the revolution of July 1830 Stendhal was appointed consul at Trieste, but since Metternich refused him his *exequatur,* he was sent in April 1831 to Civita-Vecchia. There he longed for Paris, the city of conversation He wandered about Naples, made excavations in the papal territory, continually visited Rome and took holidays in Paris between 1836 and 1839. He had not yet had any true success when he was hailed as a great novelist by Balzac in an article published on Sept. 25, 1840, in the *Revue Parisienne,* on the *Chartreuse de Parme.* He had just completed an advantageous contract with the *Revue des deux Mondes* for "nouvelles" when he was overcome on the boulevard by an attack of apoplexy on March 22, 1842 Three friends, including Mérimée, followed his funeral to the cemetery of Montmartre. He counted on obtaining a little glory about 1880 or even later: "I take a ticket in the lottery, the grand prize of which may be summed up as—to be read in 1935."

He was read long before this, and *La Chartreuse de Parme* is one of the great romances of the 19th century The hypothesis which saw in it only an ingenious reproduction of ancient Italian chronicles which Stendhal had dug out of the libraries has been exploded The value of the novel lies in the analysis of the *grandes*

passions and in his pictures of contemporary manners. It differs widely from the rude and simple stories which he liked to take as his inspiration. Stendhal has put in this book his experiences and intimate feelings, his impressions of Italy revived by nostalgia. This book was seven years in contemplation and it was finally written in Paris in seven weeks, appearing in April 1839. The first part of the book consists of memories rearranged by the author—of Milan on the morrow of Lodi, of the adventures of Fabrice, present at a great battle without seeing much of it, of France after Waterloo, of the intrigues of a little Italian court in 1820. The book is full of Stendhal's reading on Italy of former days which gives rise to certain discrepancies. The actors are original characters, even if one sees the prototype of Count Mosca in Metternich or in Count Sauron, the governor of Lombardy. The Duchess of Sanseverina differs greatly from la Vannoza, the mistress of the future Pope Alexander VI., and Fabrice del Dongo, the Napoleonic marquis who became a priest after taking part in a conspiracy, has more resemblance to Julien Sorel than to Alexander Farnese. Stendhal excels in the delineation of souls and of exceptional and complex characters, scheming and energetic. Portraits, landscapes and Italian life play a large part in this crowded and disconcerting romance. The style is always natural, clear and limpid. The "little precise phrases, worthy of a code or of algebra" raised the enthusiasm of Taine who regarded Stendhal as a "superior spirit."

From his "Italian chronicles" he repeatedly drew dark and bloody stories and horrible and romantic novels. He was amused by these stories which he published between 1829 and 1838 in the *Revue de Paris: Vanina Vanini, Le coffre et le revenant, Le Philtre. Vittoria Accoramboni, Les Cenci, La duchesse de Palliano, L'Abbesse de Castro, San Francesco a Ripa*, appeared in the *Revue des deux Mondes* (1837–53).

Stendhal's admirers have published his unpublished works and even some illegible fragments preserved in the library at Grenoble. With audacious disquieting sincerity, sometimes bordering on cynicism, Stendhal wrote autobiographies entitled *La Vie d'Henri Brulard* (1890), *Souvenirs d'Egotisme* (1892), *Lucien Leuwen* (1894), *Journal d'Italie* (1911), in order to enjoy his past and to rescue from oblivion his "so different" personality. *Lamiel* (1889) is a romance in the style of Balzac and Sue of a foundling child of a seduced peasant woman. In his correspondence, vivid, primitive, amusing, passing from irony to tenderness, he paints himself with somewhat crude freedom. It is a feast for lovers of human documents. A place apart must be given to the *Lettres à Pauline*, his younger sister, whom Stendhal adored and whom he made his confidante. *La Vie de Napoléon* (1876) is less original than might have been expected. History is mingled with legend and gossip.

Stendhal, the "hussar of romanticism," independent of all schools, was at once behind the times and a pioneer. Disciple of the ideologues and even of the philosophers of the 18th century, he nevertheless seems to have been in advance of our own generation. Almost unknown during his lifetime, Stendhal the psychologist, an expert in unravelling and analyzing the sentiments of the human heart, curious about the "little true facts," careful to "write philosophically" for a fastidious *élite*, for the "happy few," was one of the introducers of romanticism and of the psychological novel. It was all very well for him to write that "a novel is a mirror taking a walk along the high road"; his mirrors possessed a strange magic. Of him more than anyone else it may be said that he was original. There are "Stendhaliens" and "anti-Stendhaliens." Henri Beyle lives to-day more than 100 years ago.

BIBLIOGRAPHY.—Stendhal's works have been published in 17 vols. by Michel Levy (1853–55). They were republished from 1913 under the direction of Paul Arbelet and Edouard Champion (35 vols.). His correspondence has been collected and re-arranged by A. Paupe and P. Cheramy (1908) The following works are important: *Notice sur M. Beyle*, by his friend Romain Colomb (1845); Mérimée, *Henri Beyle* (1850); the articles by Sainte-Beuve, in tome IX. of the *Causeries du lundi*, and by Taine in *Nouveaux essais de critique et d'histoire;* the books of E. Rod (1892), A. Chuquet (1902), P. Martino (1914) and P. Arbelet. *La jeunesse de Stendhal* (1914). H. STENOTYPY is the substitution of a printed character for the usual shorthand phonogram. This is accomplished by means of a machine called the stenotype. The machine is equipped with 23 keys and a numeral bar and prints 16 letters of the alphabet, the numerals from zero to nine and an asterisk. The mechanism is such that any one or any combination of the 16 letters or numbers can be printed at one time on one line of a strip of paper which is fed automatically through the back of the machine. This permits the printing of several short words, a complete word or the contraction of a word at a single stroke. The keys are so arranged that the initial consonants are under the fingers of the left hand, the vowels under the thumbs, and the final consonants under the fingers of the right hand. Duplication of consonants accounts for the five additional keys. The machine weighs only about 4½lb. and is correspondingly small. The reading of the notes requires no training.

MASTER MODEL FOUR OF A STENOTYPE MACHINE

STENTOR, one of the Greeks before Troy (*Iliad* v. 783), whose "stentorian" voice was as loud as that of 50 men.

STEPHAN, HEINRICH VON (1831–1897), German statesman, was born at Stolp, Pomerania, on Jan. 7, 1831. He entered the Prussian postal service, in which he rose rapidly. He was the first postmaster-general of the German Empire and was the chief promoter of the International Postal Union, presiding at the first conference, at Bern, in 1874. He died on April 8, 1897.

See E. Knickeberg, *H. v. Stephan* (1897).

STEPHANITE, a mineral consisting of silver sulphantimonite, Ag_5SbS_4; containing 68·5% of silver, and sometimes of importance as an ore of this metal. Under the name *Schwarzerz* (black ore) it was mentioned by G. Agricola in 1546. The stephanite mineral has a hardness of 2·5 and is very brittle; the specific gravity is 6·3. It occurs with other ores of silver in metalliferous veins, as in the Comstock lode in Nevada.

STEPHANUS BYZANTINUS (STEPHEN OF BYZANTIUM), the author of a geographical dictionary entitled Ἐθνικά, of which, apart from some fragments, we possess only the meagre epitome of one Hermolaus, dedicated to Justinian; whether to the first or second emperor of that name is disputed. Stephanus probably flourished in the earlier part of the 6th century, under Justinian I. The chief fragments remaining of the original work (which contained quotations from classical authors and topographical and historical details) are preserved by Constantine Porphyrogennetos, *De administrando imperio*, ch. 23 (the article Ἰβηρίαι δύο) and *De thematibus*, ii. 10 (an account of Sicily); the latter includes a passage from the comic poet Alexis on the Seven Largest Islands. Another fragment, from the article Δύμη to the end of Δ, exists in a ms. of the Seguerian library.

See E. H. Bunbury *History of Ancient Geography*, i. 102, 135, 169; ii. 669–671 (1883); Riese, *De Stephani Byzant. auctoribus* (Kiel, 1873); J. Geffcken, *De Stephano Byzantio* (Göttingen, 1886).

STEPHEN, in some senses the greatest figure in primitive Christianity prior to Paul's conversion, was one of "the Seven" (Acts xxi. 8, nowhere called "deacons") set over the "daily ministration" towards the needy members of the Jerusalem community. Like Philip and perhaps others of his colleagues (vi. 3), he had higher gifts than his office would suggest. He was "full of faith and of holy Spirit"; and as his spiritual power showed itself in mighty deeds as well as words (vi. 5, 8), he became a marked man in Jerusalem. Himself a Jew of Greek culture, he naturally tried to win over his fellow Hellenists (vi. 9).

It is here that Stephen's advance upon prior Apostolic teaching becomes apparent. His special "wisdom" lay in greater insight into the merely relative nature and value of the externals of Israel's religion, particularly those connected with the Temple. His fellow Hellenists, as a body, were eager to disprove the feel-

ing of the native "Hebrews" that they were only half Jews. Hence teaching which minimized the value of the sacred "customs which Moses had delivered" (vi. 14), by making "salvation" depend simply on faith in Jesus as Messiah, would cause deep resentment in such circles, in spite of their more liberal attitude to things non-Jewish For in Jerusalem the Temple overshadowed men's thoughts touching the Divine presence To this he would reply in the spirit of the prophets, that the heart is the true seat of the Shekinah; and that if they refused God manifest in His Messiah, no holy "customs"—no, not the Temple itself—could save from the displeasure of the living God. Nay, he argued, quoting words of Jesus (Matt xxvi. 61, Mk. xiv. 58, Jo. ii. 10) which were easy to misquote (Acts vi. 14), that the Temple might even be destroyed, as it had been in the past, without loss to true religion. But they could not rise to this conception and treated his words as "blasphemous," and roused "the people and the elders and the scribes" against him

He was seized and brought before the Sanhedrin on the charge of speaking "against the Temple and the Law" (vi. 11–14). His defence took the form of a survey of Israel's religious past, with a view to show: (1) that "the God of Glory" had covenant relations with their forefathers before they had either Holy Place (Land or Temple) or Law (vii. 1–17); (2) that the first visible meeting place between God and His people was far other than that for which absolute sanctity was now claimed. Indeed, the form of "the tabernacle of testimony in the wilderness" (no Holy Land) had more divine sanction than any later Temple (44–47); (3) that, after all, the presence of "the Most High" was not bound up with any structure of human hands, as Isaiah witnessed (48–50) The moral of all this was plain: Israel's *forms* of fellowship with the Most High had all along been relative and subject to change. Hence there was no "blasphemy" in suggesting that in the Messianic age yet another change might come about, and that observance of Temple services could prove little as to acceptance with God. But there is another and more urgent line of pleading. This is found in the elaborate section dealing with the person and work of Moses, the great lawgiver (17–38)—a section full of extra-biblical touches—followed by one on Israel's hardness of heart towards him, together with its result, the Exile (39–43). Pure and original Mosaism is represented as something which in its full spiritual intention had been frustrated by Israel's stiffneckedness (39, 42 *seq*). The figure of Moses is made to stand forth in ideal outlines, the thinly-veiled Christian application shining through. "This is that Moses who said unto the children of Israel, 'A prophet shall God raise up unto you . . . like unto me:' who received living oracles to give unto us: to whom our fathers would not be obedient, but thrust him from them, and turned back in their hearts . . ." (38 *seq*.). Here we have the very situation as between Stephen and his hearers; and it is made unmistakable by the speaker's closing words (51–53). Had they kept the Law dutifully, they would have believed on Him in whom true Mosaism was fulfilled and transcended. The author of Acts probably owed his report of Stephen's speech (as of his whole story) to Philip the "evangelist," who had been one of the Seven (xxi. 8). Possibly also Paul had spoken in Luke's hearing of Stephen's death and his own part in it (vii. 58, 60, *cf*. vi. 9).

Stephen's martyrdom is described as tumultuary in character, though the legal forms of stoning for blasphemy were observed (vii. 58); nor is it inconceivable that an act exceeding Jewish rights under the Romans should have taken place at the sudden impulse of religious fanaticism.

See articles in the *Ency. Bib.* vol. iv., and Hauck's *Realencykl. f protestant. Theol. u. Kirche,* vol. xix. (J. V B)

STEPHEN, the name of nine popes.

STEPHEN I., bishop of Rome from about 254 to 257, followed Lucius I. He withdrew from church fellowship with Cyprian and certain Asiatic bishops on account of their views as to the necessity of rebaptizing heretics (Euseb. *H. E* vii. 5; Cypr. *Epp.* 75) He is also mentioned as having insisted on the restoration of the bishops of Merida and Astorga, who had been deposed for unfaithfulness during persecution but afterwards had repented. He is commemorated on August 2. His successor was Sixtus II

STEPHEN II., pope from March 752 to April 757, was in deacon's orders when chosen to the vacant see within twelve days after the death of Zacharias.[1] The main difficulty of his pontificate was in connection with the aggressive attitude of Aistulf, king of the Lombards The death of Stephen took place not long after that of Aistulf. He was succeeded by Paul I

STEPHEN III., pope from Aug. 7, 768 to Feb. 3, 772, was a native of Sicily, and, having come to Rome during the pontificate of Gregory III., gradually rose to high office in the service of successive popes. On the deposition of Constantine II Stephen was chosen to succeed him He was succeeded by Adrian I.

STEPHEN IV., pope from June 816 to Jan. 817, succeeded Leo III He did not continue Leo's policy, which was more favourable to the clergy than to the lay aristocracy Immediately after his consecration he ordered the Roman people to swear fidelity to Louis the Pious, to whom he found it prudent to betake himself personally in the following August. After the coronation of Louis at Reims in October he returned to Rome, where he died in the beginning of the following year. His successor was Paschal I

STEPHEN V, pope from 885 to 891, succeeded Adrian III, and was in turn succeeded by Formosus. In his dealings with Constantinople in the matter of Photius, as also in his relations with the young Slavonic Church, he pursued the policy of Nicholas I

STEPHEN VI, pope from May 896 to July–August 897, succeeded Boniface VI, and was in turn followed by Romanus. His conduct towards the remains of Formosus, his last predecessor but one (*see* FORMOSUS) excited a tumult, which ended in his imprisonment and death by strangling.

STEPHEN VII (January 929 to February 931) and STEPHEN VIII. (July 939 to October 949) were virtually nonentities, who held the pontificate while the real direction of the pontifical state was in the hands of Marozia and, afterwards, of her son Alberic, senator of the Romans.

STEPHEN IX, pope from August 1057 to March 1058, succeeded Victor II (Gebhard of Eichstädt) His baptismal name was Frederick, and he was a younger brother of Godfrey, duke of Upper Lorraine, marquis of Tuscany (by his marriage with Beatrice, widow of Boniface, marquis of Tuscany) Frederick, who had been raised to the cardinalate by Leo IX, acted for some time as papal legate at Constantinople, and was with Leo in his unlucky expedition against the Normans He shared his brother's fortunes, and at one time had to take refuge from Henry III. in Monte Cassino. Five days after the death of Victor II he was chosen to succeed him He showed great zeal in enforcing the Hildebrandine policy as to clerical celibacy He died at Florence on March 29, 1058

STEPHEN (1097?–1154), king of England, was the third son of Stephen Henry, count of Blois and Chartres, and, through his mother Adela, a grandson of William the Conqueror. Born some time before 1101, he was still a boy when he was taken into favour by his uncle, Henry I. of England, and received the honour of knighthood and the county of Mortain. In 1118 he severed his connection with Blois and Chartres, renouncing his hereditary claims in favour of his elder brother Theobald. But he acquired the county of Boulogne by marrying Matilda (*c* 1103–1152), the heiress of Count Eustace III and a niece of Henry's first wife. The old king arranged this match after the untimely loss of his son, William Atheling, in the tragedy of the White Ship; until 1125 Stephen was regarded as the probable heir to the English throne. But on the return of the widowed empress Matilda (*q v.*) to her father's court, Henry compelled Stephen and the rest of his barons to acknowledge her as their future ruler (1126). Seven years later these oaths were renewed; and in addition the ultimate claims of Matilda's infant son, Henry of Anjou, were recognized (1133). But the death of Henry I. found the empress absent from England. Stephen hurried across the Channel and began to canvass for supporters, arguing that his oaths to Matilda were taken under coercion, and that she, as the daughter of a professed nun, was illegitimate.

He was raised to the throne by the Londoners, the official

[1] A priest named Stephen, elected before him, died three days after, without having received the episcopal consecration.

baronage and the clergy; his most influential supporters were the old justiciar, Robert, bishop of Salisbury, and his own brother Henry, bishop of Winchester. Innocent II. was induced by Bishop Henry to ratify the election, and Stephen thus cleared himself from the stain of perjury. Two charters of liberties, issued in rapid succession, confirmed the King's alliance with the Church and earned the good will of the nation. But his supporters traded upon his notorious facility and the unstable nature of his power. Extortionate concessions were demanded by the great barons, and particularly by Earl Robert of Gloucester, the half-brother of the empress. The clergy insisted that neither their goods nor their persons should be subject to secular jurisdiction. Stephen's attempt to create a mercenary army and a royalist party led at once to a rupture between himself and Earl Robert (1138), which was the signal for sporadic rebellions. Soon afterwards the king attacked the bishops of Salisbury, Ely and Lincoln—a powerful family clique who stood at the head of the official baronage—and, not content with seizing their castles, subjected them to personal outrage and detention. The result was that the clergy, headed by his brother, the bishop of Winchester, declared against him (1139).

Stephen was thoroughly discredited when the empress at length appeared in England (Sept. 30, 1139). Through a misplaced sense of chivalry he declined to take an opportunity of seizing her person. She was therefore able to join her half-brother at Gloucester, to obtain recognition in the western and south-western shires, and to contest the royal title for eight years. Stephen's initial errors were aggravated by bad generalship. He showed remarkable energy in hurrying from one centre of rebellion to another, but he never ventured to attack the headquarters of the empress. In 1141 he was surprised and captured while besieging Lincoln castle. The empress in consequence reigned for six months as "Lady (*Domina*) of the English"; save for her faults of temper, the cause of Stephen would never have been retrieved. But, later in the year, his supporters were able to procure his release in exchange for the earl of Gloucester. After an obstinate siege he expelled Matilda from Oxford (Dec. 1142) and compelled her to fall back upon the west.

The next five years witnessed anarchy such as England had never before experienced. England north of the Ribble and the Tyne had passed into the hands of David of Scotland and his son, Prince Henry; Ranulf earl of Chester was constructing an independent principality; on the west the raids of the Angevin party, in the east and midlands the excesses of such rebels as Geoffrey de Mandeville, earl of Essex, turned considerable districts into wildernesses. Meanwhile Geoffrey of Anjou, the husband of the empress, completed the conquest of Normandy (1144). In 1147 the situation improved for Stephen; Robert of Gloucester, the ablest of the Angevin partisans, died, and the empress left England in despair. But her son soon appeared in England to renew the struggle (1149) and conciliate new supporters. Soon after his return to Normandy Henry was invested by his father with the duchy (1150). He succeeded to Anjou in 1151; next year he acquired Aquitaine by marriage.

Stephen struggled hard to secure the succession for Eustace, his elder son. But he had quarrelled with Rome respecting a vacancy in the see of York; the pope forbade the English bishops to consecrate Eustace (1151); and there was a general unwillingness to prolong the civil war. Worn out by incessant conflicts, the king bowed to the inevitable when Henry next appeared in England (1153). Negotiations were opened; and Stephen's last hesitations disappeared when Eustace was carried off by a sudden illness. Late in 1153 the king acknowledged Henry as his heir, only stipulating that the earldom of Surrey and his private estates should be guaranteed to his surviving son, William. The king and the duke agreed to co-operate for the repression of anarchy; but Stephen died soon thereafter (Oct. 1154).

On his great seal Stephen is represented as tall and robust, bearded, and of an open countenance. He was frank and generous; his occasional acts of duplicity were planned reluctantly and never carried to their logical conclusion. In warfare he showed courage, but little generalship; as a statesman he failed in his dealings with the Church, which he alternately humoured and thwarted. He was a generous patron of religious foundations; and some pleasing anecdotes suggest that his personal character deserves more commendation than his record as a king.

STEPHEN I. [ST. STEPHEN] (977–1038), king of Hungary, was the son of Geza, duke of Hungary, and of Sarolta, one of the few Magyar Christian ladies. His tutors included the German priest Bruno, the Czech priest Radla, and an Italian knight, Theodate of San Severino, who taught him arms and letters. In 996 Stephen married Gisela, the daughter of Duke Henry II. of Bavaria. In the following year his father died and the young prince was confronted by a formidable pagan reaction between the Drave and Lake Balaton. Stephen hastened against the rebels, bearing before him the banner of St. Martin of Tours, whom he now chose to be his patron saint, and routed the rebels at Veszprem (998), assuming the royal title immediately afterwards.

The rest of Stephen's life was spent largely in a struggle against the pagan nobles, which engrossed his energies, and compelled him to adopt a pacific policy towards the emperors of the East and West; but when attacked by the emperor Conrad in 1030 Stephen repelled the invasion successfully. He died at Esztergom in 1038 and was canonized in 1083. For an account of his reforms *see* HUNGARY: *History*.

See Antal Pór, *Life of St. Stephen* (Hung.; Pest, 1871); Lajos Balics, *History of the Roman Catholic Church in Hungary*, vol. i. (Hung.; Pest, 1885); János Karácsonyi, *Documents issued by Stephen I.* (Hung.; Pest, 1892), idem, *Life of St. Gellert* (Hung.; Pest, 1887); W. J. Winkler de Kétrszynski, *Vita sancti Stephani* (Cracow, 1897); E. Horn, *St. Etienne, roi apostolique de Hongrie* (1899).

STEPHEN V. (1239–1272), king of Hungary, was the eldest son of Béla IV., whom he succeeded in 1270. In 1262, as crown prince, he had compelled his father, whom he had assisted in the Bohemian War, to surrender 29 counties to him, virtually dividing Hungary into two kingdoms; while afterwards he seized the southern banate of Macso, which led to a fresh war between father and son in which the latter triumphed. In 1268 he invaded Bulgaria and assumed the title of king of Bulgaria. During his father's lifetime Stephen had a double matrimonial alliance with the Neapolitan princes of the House of Anjou, the chief partisans of the pope. He certainly needed exterior support; for on his accession to the Hungarian throne he encountered almost universal hostility owing to his alleged pagan leanings, due largely to the influence of his Cuman wife Elizabeth, to whom his father had married him for political reasons in 1255. The malcontents combined with Ottakar II. of Bohemia, and invaded western Hungary; but Stephen routed Ottakar at Mosony (1271) and was preparing to recover his infant son Ladislaus whom the rebels had kidnapped, when he died suddenly on Aug. 6, 1272.

STEPHEN, SIR JAMES FITZJAMES, BART. (1829–1894), English lawyer, judge and publicist, was born in London on March 3, 1829, the third child and second son of Sir James Stephen. He was educated at Eton, London university, and Trinity, Cambridge. He was already acquainted with Sir Henry Maine (*q.v.*), six years his senior, and then newly appointed to the chair of civil law. This acquaintance now ripened into a perfect friendship, which ended only with Maine's death in 1888.

Stephen was called to the bar in 1854, and in 1859 he was appointed recorder of Newark. In 1863 he published his *General View of the Criminal Law of England* (2nd recast ed. 1890). This was the first attempt that had been made since Blackstone to explain the principles of English law and justice in a literary form, and it had a thoroughly deserved success. All this time Stephen kept up a great deal of miscellaneous writing, and the foundation of the *Pall Mall Gazette* in 1865 gave him a new

field. The decisive point of his work was in the summer of 1869, when he accepted the post of legal member of council in India. Fitzjames Stephen's friend Maine was his immediate predecessor in this office. Guided by Maine's comprehensive genius, the government of India had entered on a period of systematic legislation which was to last about twenty years. The materials for considerable parts of this plan had been left by Maine

Stephen had the task of working them into their definite shape and conducting the bills through the Legislative Council. This he did with wonderful energy, with efficiency and workmanship adequate to the purpose, if sometimes rough according to English notions, and so as to leave his own individual mark in many places. The Native Marriages Act of 1872 was the result of deep consideration on both Maine's and Stephen's part. The draft of the Contract Act was materially altered in Stephen's hands before, also in 1872, it became law. The Evidence Act of the same year was entirely Stephen's own. He came home in 1872.

Indian experience had supplied Stephen with the motive for his next piece of work, which historians of the common law may well regard as his greatest title to remembrance. The materials which Stephen had long been collecting took permanent shape in the *History of the Criminal Law of England* (1883), which, though not free from inequalities and traces of haste, must long remain the standard work on the subject. The Bills of Exchange Act (1882), the Partnership Act (1890), the Sale of Goods Act (1893) and the Marine Insurance Act (passed 1906) are indirectly due to his efforts. In 1879 Stephen became judge of the queen's bench division. He resigned that office in April 1891, after a breakdown, and died on March 11, 1894, having filled a not very long life with a surprising amount of work, of which a large proportion was of permanent value. He married Mary Cunningham in 1855

See Sir Leslie Stephen, *Life of Sir James Fitzjames Stephen* (London, 1895), with bibliographical appendix, a model biography, same author's article in the *Dict Nat. Biog*; *Letters with biographical Notes*, by his daughter, Caroline Emelia Stephen (1907) *See* also Sir C. P. Ilbert, "Sir James Stephen as a Legislator," *Law Quart. Rev.* x. 222.

STEPHEN, SIR LESLIE (1832–1904), English philosopher and man of letters, son of Sir James Stephen, was born in London on Nov. 28, 1832. He was educated at Eton, at King's college, London, and Trinity Hall, Cambridge. In 1854 Stephen obtained a Goodbehere fellowship, and was ordained deacon on Dec. 21, 1855, becoming a priest in 1859. In 1856 he was admitted to a junior tutorship at Trinity Hall He was a good athlete and a mountaineer His first ascent was in 1857 (Col du Géant), and he made many others in the following years, until his first marriage in 1867. He was president of the Alpine club from 1865 to 1868, and editor of the *Alpine Journal* from 1868 to 1871. His accounts of his mountaineering feats were published in various journals, and collected in *The Playground of Europe* (1871). In the meantime, during his residence at Trinity Hall, his philosophical studies led him to abandon the orthodox theological position, and in 1875 he relinquished his orders He interested himself in university politics, and advocated the need for examination reforms. During the American Civil War he was greatly in sympathy with the North, and in 1863 visited America to investigate the situation. On his return he published *The Times and the American War by L. S.* (1865), in answer to English arguments in support of the South. Stephen came to London in 1864, with useful recommendations from his brother Sir J. Fitzjames Stephen. He contributed for many years to the *Saturday Review*, and from 1865 co-operated with George Smith in the foundation of the *Pall Mall Gazette*. From Oct. 1866 to Aug. 1873 he contributed political articles to the *Nation*. His literary criticisms for the *Cornhill Magazine* (from 1866) were collected from time to time in separate volumes, as *Hours in a Library* (1874, 1876 and 1879). In 1871 he became editor of the *Cornhill*, and during the 11 years of his editorship the magazine made a reputation by its literary excellence. R. L. Stevenson, Thomas Hardy, Henry James and Edmund Gosse were among his contributors. In his *Essays on Free Thinking and Plain Speaking* (1873) Stephen challenged the dogmas of popular religion. His *History of English Thought in the Eighteenth Century* (2 vols., 1876), later extended into *The English Utilitarians* (1900), remains a standard work on the subject. He married in 1867 the younger daughter of W. M. Thackeray, and in 1868 visited America with her, where he met Emerson and Oliver Wendell Holmes the younger.

In Nov. 1882 George Smith made Stephen editor of the *Dictionary of National Biography*, which he conducted until April 1891, continuing to contribute until 1901. His first wife died in 1875, and in 1878 he married again. In his later years he was greatly affected by the death first of his brother James (1894), and shortly afterwards (1895) of his wife. One of his daughters, Mrs. Virginia Woolf, is separately noticed in this book. Stephen received many marks of distinction, and in 1902 was made K.C.B. He continued his literary work almost to the end of his life, and his last books were a monograph on Hobbes (1904), and his Ford lectures, *English Literature and Society in the Eighteenth Century*, published on the day of his death, Feb. 22, 1904. His work, both philosophical and literary, is remarkable for the sincerity of the author's outlook, and for his unprejudiced judgments. He wrote also *Social Rights and Duties* (1896); *Science and Ethics* (1882); *An Agnostic's Apology* (1893); *Studies of a Biographer* (2 vols., two series, 1899 and 1902), and monographs for the "English Men of Letters" series.

See F. W. Maitland, *Life and Letters of Leslie Stephen* (1906); Sir Sidney Lee, *Principles of Biography* (the Leslie Stephen lecture, 1911).

STEPHEN (ISTVÁN) BÁTHORY (1533–1586), king of Poland and prince of Transylvania. Báthory spent his early years at the court of the emperor Ferdinand, subsequently attached himself to Janos Zapolya, and won equal renown as a soldier and diplomatist. Zapolya rewarded him with the voivodeship of Transylvania, where his defence of the rights of his patron's son, John Sigismund, incurred the animosity of the emperor Maximilian, who kept him in prison for two years. On May 25, 1571, on the death of John Sigismund, Báthory was elected prince of Transylvania by the Hungarian estates, in spite of the opposition of Vienna. He expelled the rival candidate, Gaspar Békesy, from Transylvania (1572). In 1579 the Polish nobility, at the instigation of Zamoyski (*q v*) elected Báthory king of Poland, in opposition to the emperor Maximilian, the candidate of the senate. Báthory persuaded the Transylvanian estates to elect his brother Christopher in his stead, hurried to Cracow, espoused the princess Anne, the sister of the last Jagiello, and was crowned on May 1.

The leading events of Stephen Báthory's reign can here only be briefly indicated. All armed opposition collapsed with the surrender of Danzig, after a six months' siege, on Dec. 16, 1577. Stephen was now able to devote himself to foreign affairs. The difficulties with the sultan were temporarily adjusted by a truce signed on Nov. 5, 1577; and the Diet of Warsaw having voted supplies, Stephen embarked on war with Muscovy. Penetrating to the heart of the country, he besieged Pskov (Aug.–Dec. 1581), and forced Ivan the Terrible to cede him Polotsk and Livonia (peace of Zapoli, Jan. 15, 1582). The chief domestic event of Stephen's reign was the establishment in Poland of the Jesuits, in furtherance of his designs of uniting Poland, Muscovy and Transylvania into one great state. The project was dissipated by his sudden death, of apoplexy, Dec. 12, 1586.

See I. Polkowski, *The Martial Exploits of Stephen Báthory* (Pol.; Cracow. 1887); Paul Pierling, *Un Arbitrage pontifical au xvi^me siècle* (Brussels, 1890); Lajos Szadeczky, *Stephen Báthory's Election to the Crown of Poland* (Hung.; Budapest, 1887).

STEPHENS, ALEXANDER HAMILTON (1812–1883), American statesman, vice president of the Confederate States during the Civil War, was born in Wilkes (now Taliaferro) county, Georgia, on Feb. 11, 1812. He was a weak and sickly child of poor parents, and from his sixth to his 15th year, when he was left an orphan, he worked on a farm. After his father's death he went to live with an uncle in Warren county. The superintendent of the local Sunday school sent him to an academy at Washington, Wilkes county, for one year and in the following year (1828) he was sent by the Georgia Educational society to Franklin college (University of Georgia), where he graduated in 1832. Deciding

not to enter the ministry, he paid back the money advanced by the society. He was a schoolmaster for about two years, and then was admitted to the bar in 1834.

In 1836 he was elected to the Georgia house of representatives after a campaign in which he was vigorously opposed because he had attacked the doctrine of nullification, and because he had opposed all extra-legal steps against the abolitionists. He was annually re-elected until 1841; in 1842 he was elected to the State senate, and in the following year, on the Whig ticket, to the national House of Representatives. In this last body he urged the annexation of Texas, chiefly as a means of achieving more power for the South in Congress. He was denounced as a traitor to his party because of his support of annexation, but he later became the leader of the Whig opposition to the war with Mexico. He vigorously supported the Compromise Measures in 1850, and continued to act with the Whigs of the North until they, in 1852, nominated Gen. Winfield Scott for the presidency without Scott's endorsement of the Compromise. Stephens and other Whigs of the South then chose Daniel Webster, but a little later they joined the Democrats. In 1854 Stephens helped to secure the passage of the Kansas-Nebraska Bill. Before the Georgia legislature in Nov. 1860, and again in that State's secession convention in Jan. 1861, he strongly opposed secession, but when Georgia seceded he "followed his state," assisted in forming the new government, and was elected vice president of the Confederacy. Throughout the war, he was so concerned about States' rights and civil liberty that he opposed the exercise of extra-constitutional war powers by President Jefferson Davis lest the freedom for which the South was fighting should be destroyed. His policy was to preserve constitutional government in the South and strengthen the anti-war party in the North by convincing it that the Lincoln administration had abandoned such government; to the same end he urged, in 1864, the unconditional discharge of Federal prisoners in the South. Stephens headed the Confederate commission to the peace conference at Hampton Roads in Feb. 1865. In the following May, after the fall of the Confederacy, he was arrested at his home and taken to Fort Warren, in Boston harbour, where he was confined until Oct. 12. In 1866 he was elected to the United States Senate, but was not permitted to take his seat. He was a representative in Congress, however, from 1873 to 1882, and was governor of Georgia in 1882–83, dying in office, at Atlanta, on March 4, 1883.

From 1871 to 1873 he edited the *Atlanta Daily Sun*, and he published *A Constitutional View of the Late War between the States* (1868–70), perhaps the best statement of the Southern position with reference to state sovereignty and secession; *The Reviewers Reviewed* (1872), a supplement to the preceding work; and *A Compendium of the History of the United States* (1875; new ed., 1883).

Stephens in Public and Private, with Letters and Speeches* (Philadelphia, 1866); M. L. Avary (ed.), *Recollections of A. H. Stephens*, with a biographical study (1910); U. B. Phillips (ed.), "The Correspondence of Robert Toombs, Alexander H. Stephens and Howell Cobb," in *American History Association, Annual Report*, vol. ii. (1911); and Gamaliel Bradford, *Confederate Portraits* (1914).

STEPHENS, JAMES (1882–), Irish poet, was born in Dublin. He was earning his living as a clerk in Dublin when he made his name by the exquisite prose of the delightful fairy stories published as *The Crock of Gold* (1912). He shows a sense of fantasy and a delicate poetic talent in all his works. The later ones include *Reincarnation* (1918); *Deirdre* (1923); *In the Land of Youth* (1924); *Collected Poems* (1926) and *Etched in Moonlight* (1928). Stephens was an ardent Nationalist, and worked hard for the creation of the Irish Free State.

STEPHENS, JOHN LLOYD (1805–1852), American traveller, was born Nov. 28, 1805, at Shrewsbury, N.J. Having been admitted to the bar, he practised for about eight years in New York city. In 1834–36 he made extensive travels in Europe, Egypt and Syria. In 1839 Stephens arranged with Frederick Catherwood to make an exploration in central America, with a view to discovering and examining the antiquities said to exist there. Stephens, meantime, was appointed to a mission to central America. Stephens published in 1841 *Incidents of Travels in Central America, Chiapas and Yucatan.* A second visit (1841) to Yucatan is described in *Incidents of Travel in Yucatan* (1843). Stephens died at New York on Oct. 10, 1852.

STEPHENSON, GEORGE (1781–1848), English engineer, was the second son of Robert Stephenson, fireman of a colliery engine at Wylam, near Newcastle, where he was born on June 9, 1781. In boyhood he was employed as a cowherd, and afterwards he drove the "gin-horse" at a colliery. At 14 he became assistant fireman to his father at a shilling a day, and at 17 he was appointed plugman, his duty being to attend to the pumping-engine. As yet he was unable to read, but stimulated by a desire to study the inventions of Boulton and Watt, he attended a night school and made rapid progress. In 1801 he became brakesman, in 1802 engineman at Willington Quay, where he took up watch and clock cleaning in his spare time. In 1804 he moved to Killingworth, where in 1812 he was appointed engine-wright of the High Pit at a salary of £100 a year. It was here in 1815 that he devised his miner's safety lamp, at the time when Sir Humphry Davy was also producing his lamp, a coincidence which led to much controversy.

In 1813 Stephenson was authorised to build a "travelling engine" for the tramroads between the Killingworth colliery and the port 9 mi. away on the plan of one already running at Wylam. The engine, which was named "Blucher," ran a successful trial on July 25, 1814, and in 1822 he persuaded the directors of the Stockton and Darlington railway (then in construction) to use steam instead of animal traction. At the opening of this railway on Sept. 27, 1825, therefore, the first public passenger train in the world was drawn by Stephenson's locomotive "Active," which was subsequently renamed "Locomotion." His connection with the Stockton and Darlington led to his employment on the Liverpool and Manchester railway, whose track he carried successfully over Chat Moss. When the line was nearing completion he persuaded the directors, who favoured haulage by fixed engines, to give the locomotive a trial. They offered a prize of £500 for a suitable machine, and in the Rainhill trials in October, 1829, Stephenson's engine, "The Rocket," was chosen. (For a description see *Steam Engine.*) On September 15, 1830, the railway was formally opened, the eight engines employed having been built at the works started at Newcastle in 1823 by Stephenson, his cousin Thomas Richardson, and Edward Pease. Stephenson was engineer of the Grand Junction, London & Birmingham (with his son Robert), Manchester to Leeds, Derby to Leeds, Derby to Birmingham, and Birmingham to York railways; but he strongly disapproved of the "railway mania" of 1844. He was also consulted about the construction of railways in Belgium and Spain. The last years of his life were spent in retirement at Tapton House, Chesterfield, in farming and horticulture, and there he died on Aug. 12, 1848.

See *Life of George Stephenson*, by Samuel Smiles (1857, new ed., 1881); and Smiles's *Lives of the Engineers*, vol. v. (1873).

STEPHENSON, GEORGE ROBERT (1819–1905), British civil engineer, was born at Newcastle-on-Tyne on Oct. 20, 1819, and was the nephew of George Stephenson (1781–1848) (*q.v.*). After working in colliery workshops near Manchester, he was sent to King William's School, Isle of Man. After his father's death in 1837, he worked for his uncle in the drawing-office of the Manchester and Leeds railway. In 1860, when he was consulting engineer to the provincial government of Canterbury, New Zealand, the Lyttelton-Christchurch line was built under his direction. He returned to England, and with Sir John Hawkshaw in 1864 built the East London railway. He was partly responsible for the construction of the Victoria tubular bridge across the St. Lawrence, and designed many bridges in England and abroad. In 1859 he succeeded his cousin Robert Stephenson (*q.v.*) at the locomotive works at Newcastle-on-Tyne, and at the Snibston and Tapton collieries. He died at Cheltenham on Oct. 26, 1905.

STEPHENSON, ROBERT (1803–1859), English engineer, only son of George Stephenson (*q.v.*), was born at Willington Quay on Oct. 16, 1803. He spent four years at school in New-

castle, and was then (1819) apprenticed to Nicholas Wood, a coal-viewer at Killingworth, after which he was sent in 1822 to attend science classes at the university of Edinburgh. He assisted his father in surveying the Stockton and Darlington and Liverpool and Manchester railways, and in 1824 he took charge of the engineering operations in South America of the Colombian Mining Association of London. He resigned in 1827, and returned to England via New York in company with Richard Trevithick, whom he had met in a penniless condition at Cartagena. Stephenson then undertook the management of his father's factory in Newcastle, and assisted in the improvement of the locomotive. His work extended to Sweden, Denmark, Belgium, Switzerland and Egypt. He specialised in the construction of railway bridges, especially those of the tubular girder type, and among his more notable examples are the Royal Border bridge at Berwick-on-Tweed, the High Level bridge at Newcastle-on-Tyne, the Britannia tubular bridge over the Menai Straits, the Conway tubular bridge, and the Victoria tubular bridge over the St. Lawrence at Montreal. In 1847 he entered the House of Commons as member for Whitby, retaining the seat till his death in London on Oct. 12, 1859. He was buried in Westminster Abbey.

See *The Story of the Life of George Stephenson, including a Memoir of his Son Robert Stephenson*, by Samuel Smiles (1857; new ed 1881); Jeaffreson, *Life of Robert Stephenson* (2 vols, 1864), and Smiles's *Lives of the Engineers*, vol. v. (1873)

STEPNEY, an eastern metropolitan borough of London, England, bounded north by Bethnal Green, east by Poplar, south by the river Thames, and west by the City of London and Shoreditch. Pop. (1921) 249,657; area, 1,767 acres The thoroughfares of Mile End Road and Whitechapel Road and that of Commercial Road East traverse the borough from the east and converge near the City boundary, where stood the ancient Aldgate. In the north Stepney includes the districts of Spitalfields, Whitechapel and Mile End, and in the south Wapping, Shadwell, Ratcliff and Limehouse The name appears in Domesday and later as *Stevenhethe*. The suffix is thus the common form *hythe*, a haven; but for the prefix no certain derivation is offered At Mile End, so called from its distance from the City (Aldgate), Wat Tyler and Richard II met in 1381. Pepys records the village as a favourite place of resort. The district of Spitalfields has an old association with the silk-weaving industry, a trade in singing birds is also characteristic of this district. Wharves and factories line the river bank In the extreme west the borough includes within its bounds the historic Tower of London (*q.v.*), the Royal Mint and the Tower Bridge over the Thames Stepney is a suffragan bishopric in the diocese of London. The metropolitan borough of Stepney returns three members to Parliament, one each for the Limehouse, Mile End and Whitechapel and St. George's divisions.

STEPNIAK, SERGIUS (1852–1895), Russian revolutionist, whose real name was Sergius Michaelovich Kravchinski, was born in South Russia, of noble parents He became an officer in the artillery; but his sympathy with the peasants, among whom he had lived during his boyhood in the country, developed in him at first democratic and, later, revolutionary opinions He began secretly to sow the sentiments of democracy among the peasants. His teaching did not long remain a secret, and in 1874 he was arrested He succeeded in making his escape—possibly he was permitted to escape on account of his youth—and immediately began a more vigorous campaign against autocracy. His sympathetic nature was revolted by the brutal methods adopted towards prisoners, especially political prisoners, and by the stern measures of repression of revolutionary sentiment For a time he supported a terrorist policy, and in 1880 he was obliged to leave the country. He settled for a short time in Switzerland, and after a few years came to London He was already known in England by his book *Underground Russia*, which had been published in London in 1882. He followed it up with other works on the condition of the Russian peasantry, on Nihilism, and on the conditions of life in Russia. Stepniak was killed by a railway engine at a level crossing at Bedford Park, Chiswick, on Dec 23, 1895.

STEPPE, the level treeless Russian plains and thence sometimes extended as a type-name for similar plains elsewhere; specifically it is usually applied to the plains in the south and south-east of European Russia and in the south-west of Asiatic Russia, and in this connection the term connotes level grassy areas on which the slight summer rainfall with a winter deficiency produces patches with semi-desert conditions.

STERCORARIIDAE: *see* SKUA.

STEREOBATE, in architecture, the rough masonry substructure, or foundation, of a Greek temple.

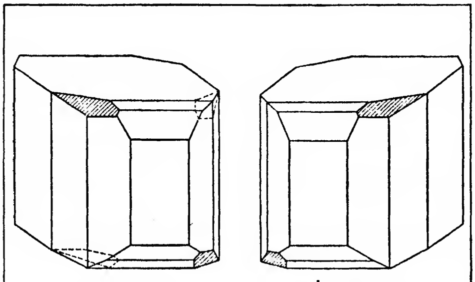
STEREOCHEMISTRY is a branch of chemistry which is concerned with the arrangement in space of the atoms in the molecules of which substances are composed (Gr. στερεός, solid). Knowledge regarding the spatial configuration of molecules has been acquired chiefly through the investigation of examples of *stereoisomerism*, a type of isomerism in which the isomers exhibit the same chemical reactions (and therefore possess the same chemical structure) and yet differ in certain physical properties; for differences between compounds of the same structure can only be due to differences in the arrangement of the atoms in their molecules in space.

The fundamental principles of stereochemistry were established by Louis Pasteur in a series of investigations on tartaric acid, carried out chiefly during the years 1849–53 Tartaric acid is obtained as a by-product in the manufacture of wine, being deposited from the fermented must in the form of potassium hydrogen tartrate The crude salt contains, however, a small proportion of the potassium hydrogen salt of another acid of the same composition named racemic acid. Now tartaric and racemic acid not only have identical chemical compositions but they also possess the same chemical structure Yet they show certain marked differences in properties For example, racemic acid is much less soluble in water than tartaric acid and crystallizes with water of crystallization, whereas tartaric acid separates in anhydrous crystals, but the most remarkable difference between the two substances is in their effect on plane-polarized light. Many naturally occurring substances of organic origin, such as sugar, camphor and oil of turpentine, possess, even in the liquid or dissolved state, the curious property of rotating the plane of polarization of a beam of plane-polarized light through an angle proportional to the thickness traversed. Tartaric acid and the tartrates have this property, being *dextrorotatory* (*i e*, they rotate the plane of polarization to the right, or in the sense which is clockwise when regarded in the direction contrary to that in which the light is travelling), while racemic acid and the racemates are optically inactive

Pasteur's discoveries arose out of a crystallographic investigation of tartaric acid He observed that there was a certain lack of symmetry in the crystalline form of this substance of such a kind that the crystal was non-superposable on its mirror-image The crystal and its image thus differ in the same kind of way as the right hand from the left hand. He prepared and examined 19 different salts of tartaric acid and found that each of these showed a similar lack of symmetry in its crystalline form. Thus fig. 1*a* represents the crystalline form of one of these salts, sodium ammonium tartrate If the crystal possessed the full symmetry of the system to which it belongs, two faces, corresponding with the two shaded, should be found in the positions indicated by dotted lines These faces, instead of occurring 8 times in the crystal, occur only 4 times (there are of course two corresponding faces on the back of the crystal not shown in the figures) and such faces, occurring only half as frequently as the full symmetry of the crystal demands, are termed *hemihedral faces.* The sodium ammonium tartrate crystal, on account of the presence of these hemihedral faces, is evidently non-superposable on its mirror-image represented in fig. 1*b*. In contrast to tartaric acid and the tartrates, racemic acid and such of its salts as Pasteur examined (with one exception, which will be considered below) crystallize in symmetrical forms superposable on their mirror-images. The optically active tartrates thus crystallize in dissymmetric forms, whilst the optically inactive racemates yield symmetrical crystals.

Pasteur's chief discovery was made through investigating the exceptional racemate referred to above, which was sodium am-

monium racemate. Crystallized under certain conditions this salt yielded crystals which unlike those of the other racemates exhibited hemihedral faces, but the crystals were of two kinds. Some were identical in form with dextrorotatory sodium ammonium tartrate (fig. 1*a*) and were in fact crystals of that salt. The other crystals differed from these only in that their hemihedrism was in the opposite sense; they were the realization of the mirror-



FROM STEWART, "STEREO-CHEMISTRY" (LONGMANS GREEN & CO.)

FIG. 1.—(A & B) ENANTIOMORPHOUS CRYSTALS OF SODIUM AMMONIUM TARTRATE

image of sodium ammonium tartrate: they had thus the form represented in fig. 1*b*. When picked out from the mixture and dissolved in water they gave a laevorotatory solution; and the acid extracted from them had a crystalline form which was the mirror-image of that of tartaric acid, and its solutions were laevorotatory.

This new acid has exactly the same solubility, melting point, specific gravity, etc., as tartaric acid; in all such properties the two acids are identical. They differ in that, (1) solutions of the new *laevorotatory* acid rotate the plane of polarization exactly as much to the left as equivalent solutions of tartaric acid rotate it to the right, and (2) their crystals cannot be superposed; their hemihedrism is in opposite senses. In the two compounds, therefore, all properties are identical except those which have direction, and these are equal and opposite. The only relationship between their molecules that can give this relationship in properties is evident; the molecules must be related as object to mirror-image. The reason why tartaric acid exists in two forms is thus that its molecule has a lack of symmetry that renders it non-superposable on its mirror-image, so that right- and left-handed forms of the molecule are possible. The dextrorotatory tartaric acid obtained directly from grape-juice is termed *dextro*-tartaric (or *d*-tartaric) acid, and the laevorotatory modification extracted from sodium ammonium racemate is known as *laevo*-tartaric (or *l*-tartaric) acid.

When concentrated solutions of *d*-tartaric and *l*-tartaric acids are mixed, the less soluble racemic acid crystallizes at once from the mixture. Racemic acid is evidently composed of molecules of *d*- and *l*-tartaric acids in equal proportions, and its optical inactivity is the result of the summation of the equal and opposite activities of its components. In the crystal of racemic acid the *d*- and *l*-molecules are packed together in pairs; such a crystal may therefore be compared with a large package of pairs of gloves. The salts of racemic acid similarly crystallize almost invariably in uniform crystals composed of pairs of the *d*- and *l*-molecules. Under exceedingly special conditions, however—in the case of a particular salt, the sodium ammonium double salt, and provided that crystallization takes place below 27° C—the constituent *d*- and *l*-tartrates crystallize in separate crystals, just as under exceptional circumstances gloves might be packed with right-hand and left-hand gloves in separate packages.

The discovery of *l*-tartaric acid thus revealed the significance of optical activity in liquid and dissolved substances. All natural objects can be divided into two classes: (i.) those which are superposable, and (ii.) those which are non-superposable on their mirror-images. It is evident that a substance of which the molecules belong to the first class can only exist in one form and cannot be optically active in the liquid or dissolved state, for in view of the symmetry of its molecules there can be nothing in them to cause the rotation of the plane of polarization in one direction rather than in the other. The molecules of substances that are optically active in the liquid or dissolved state must therefore belong to the second class, and such molecules are necessarily capable of existence in enantiomorphous (opposite-shaped) forms, and the optical activities of these forms must be equal and opposite; these complementary forms are termed *enantiomorphs antimers* or *optical antipodes*. Optically active substances must therefore occur in pairs. To every naturally occurring optically active compound there should be an optical antipode. Many of these are known as, for example, the laevorotatory antipodes of glucose and camphor, whilst others still await discovery.

To express the fact that a substance is composed of molecules which are non-superposable on their mirror-images, Pasteur introduced a new term. He described such substances as possessing *molecular dissymmetry*. The fundamental principle established by his investigations may thus be stated as follows: *If any substance exhibits optical activity in the liquid or dissolved state it possesses molecular dissymmetry.* The converse principle is also to be regarded as well established (for it now rests on a very broad experimental basis), namely, *Every molecularly dissymmetric substance is capable of showing optical activity in the liquid or dissolved state.* It would appear also that the *d*- and *l*-modifications of a molecularly dissymmetric substance crystallize in enantiomorphous forms, though the enantiomorphism may be difficult to detect.

Separation of the Antimeric Forms.—When a molecularly dissymmetric substance is prepared in the laboratory from inactive materials, an optically inactive mixture composed of equal parts of its dextro- and laevo-modifications must be formed, since there will be no asymmetric influence to favour the formation of one antimer rather than the other. The experimental demonstration of the molecular dissymmetry of a synthetic compound therefore always involves the resolution of the initially formed inactive mixture into its active antimeric components. The separation of antimeric substances requires, however, the use of special methods, since the processes of fractional crystallization and distillation usually employed for the isolation of individual substances are inapplicable, for antimers have equal solubilities in all solvents and equal vapour pressures at all temperatures. The special processes by which the resolution of molecularly dissymmetric substances can be effected are of three types which may be entitled: (i.) The method of manual separation of the enantiomorphous crystals of the antimers, (ii.) the method of conversion of the mirror-image isomers into diastereoisomers, (iii.) the biochemical method.

(i.) The first method is illustrated by Pasteur's separation of the antimeric sodium ammonium tartrates. Whilst it is thus of great historical interest, it has been of comparatively little practical value in the subsequent development of stereochemistry on account of its exceedingly limited applicability, for when an equimolecular mixture of the *d*- and *l*-forms of a molecularly dissymmetric substance crystallizes, it almost always happens that uniform crystals, built up of pairs of enantiomorphous molecules, are formed. Such crystals, being analogously constituted to those of racemic acid, are termed *racemic crystals,* and the association of *d*- and *l*-molecules of which they are formed is termed a *racemic compound,* though there is no evidence that the molecules constituting each pair are linked by forces different from the cohesive forces binding together the molecules in a crystal.

(ii.) The second method of resolution may be illustrated by considering the salt of an inactive molecularly dissymmetric acid with an active base. If the symbols + and − are used to denote enantiomorphous configurations, the antimeric forms of the acid may be represented as (+A) and (−A), and the base, *e.g.*, a laevorotatory alkaloid, as (−B). Combination of the acid and the base will then yield the two salts (+A) (−B) and (−A) (−B). It is clear then that two compounds which can be thus repre-

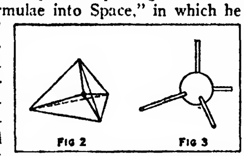
sented are not antimeric; they are said to be *diastereoisomeric* Similarly an inactive dissymmetric base (+B), (−B) will give rise with a dextrorotatory acid (+A) to the diastereoisomeric salts (+A) (+B), (+A) (−B). Diastereoisomeric compounds, being different and not antimeric, must differ to a greater or less degree in all their properties, and a pair of diastereoisomeric salts may in fact differ very considerably in solubility so that they can be easily separated by fractional crystallization Each then yields on decomposition one of the pure antimeric forms of the acid or base as the case may be. This is the most important of the methods of resolution, and most of the very large number of optically active substances that have been prepared artificially have been obtained by its means

(iii) The biochemical method depends on the different effects of living organisms on antimeric compounds. Thus moulds grown in a solution of ammonium racemate destroy the *d*-tartrate and leave the *l*-tartrate; yeasts added to solutions of inactive glucose ferment the naturally occurring *d*-glucose and leave the *l*-antimer; similarly, rabbits fed with the inactive forms of common α-amino-acids assimilate or destroy the active modification occurring in nature and excrete the other Since digestive chemical changes are mainly effected through enzymes, the biochemical method of resolution evidently depends on the well-known high specificity of enzyme action. Enzymes act very unequally on antimers, and must therefore themselves be dissymmetric; Emil Fischer used the simile that the enzyme fits the substrate as the key fits the lock

THE STEREOCHEMISTRY OF CARBON

The most symmetrical arrangement possible for the valencies of a quadrivalent element is that in which their relative directions correspond with those of the four axes of a regular tetrahedron (fig 2)

This view of the spatial distribution of the carbon valencies was adopted by F. A. Kekulé as early as 1867, and he had models constructed to represent the carbon atom, somewhat of the form shown in fig 3, consisting of a sphere with four rods attached in the directions of the axes of a circumscribed regular tetrahedron. It was, however, a few years later (1873) that the attention of chemists was first directed seriously to the need for considering the spatial configuration of molecules. In that year J Wislicenus showed that the lactic acid of sour milk and the sarcolactic acid of muscle juice (which differed in the hydration and solubility of their salts and in their optical properties, the latter being optically active) had the same chemical structure, and hence concluded that their difference could only be due to the different position of their atoms in space In the following year J H van't Hoff published a pamphlet entitled "A Proposal respecting the Extension of Chemical Structural Formulae into Space," in which he showed that the "tetrahedral" theory of the arrangement of the carbon valencies supplied an interpretation of the molecular dissymmetry of organic compounds which was in accordance with the experimental facts Similar views were put forward almost simultaneously by Le Bel



FIGS 2, 3—TETRAHEDRAL DISTRIBUTION OF VALENCIES IN A SINGLE CARBON ATOM

On van't Hoff's theory the molecule of a carbon compound of the type C *a b c c* has the configuration I, as shown in fig 4, and this has a plane of symmetry, namely, the plane passing through the edge *a b* and the middle point of *c c* cutting the tetrahedron in half as indicated by the dotted line; the molecule is therefore superposable upon its mirror-image, and a compound of this type should exist in one modification only Replacement in this compound of one of the two radicals *c* by a fourth radical *d* will give, however, two enantiomorphous configurations, II and III, according as the one or the other of these two radicals is replaced, for this substitution destroys the plane of symmetry and leaves a completely asymmetric molecule A compound of the type C *a b c d* containing a carbon atom linked to four different radicals should therefore be molecularly dissymmetric and should exist, according to the principles established by Pasteur, in two antimeric optically active forms. A carbon atom thus linked is termed an *asymmetric carbon atom*

This conclusion accorded well with the observed distribution of optical activity in organic compounds. All optically active com-

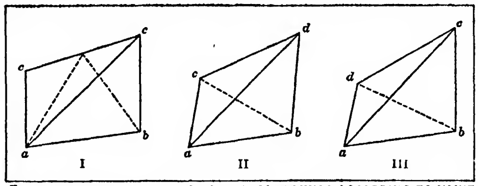


FIG 4.—CONFIGURATION OF CARBON COMPOUNDS ACCORDING TO VAN'T HOFF'S THEORY

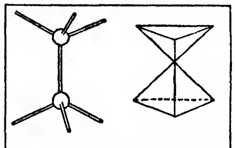
pounds of which the constitution was known contained a carbon atom linked in this manner This is illustrated by the following formulae of optically active compounds

Lactic acid Malic acid Asparagine Amyl alcohol

When we come to consider the configuration of compounds containing more than one carbon atom, a further question arises In addition to knowing the relative positions of the valency bonds of the individual atoms we should have some idea of the orientation of the different atoms relatively to one another in the molecule Evidently the valencies linking two carbon atoms together will lie in a straight line as illustrated by the models shown in fig 5 (tetrahedral axes) and fig. 6 (solid tetrahedra), and the experimental facts indicate that the two atoms can rotate freely about this line as an axis, for compounds like $CH_2Br{-}CH_2Br$, ethylene bromide, or $HO_2C\,CH_2{-}CH_2{\cdot}CO_2H$, succinic acid, exist in one modification only. The two halves of such molecules must therefore be capable of rotating about the linking by which they are united so as to assume the relative position of maximum stability These two simple assumptions of the *tetrahedral distribution of the carbon valencies* and *free rotation about a single linking* provide so complete an explanation of practically the whole of the stereochemistry of carbon that there can be little doubt of their essential correctness.



FIGS 5 6—TETRAHEDRAL DISTRIBUTION OF VALENCIES OF TWO CARBON ATOMS

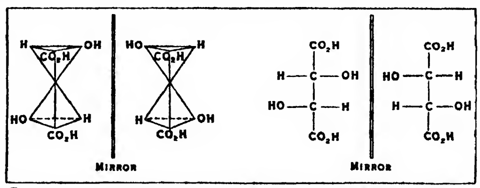


FIG 7—ENANTIOMORPHOUS CONFIGURATIONS AND PROJECTION FORMULAE OF THE TRANS-D- AND L-TARTARIC ACIDS

THE STEREOCHEMISTRY OF OPEN-CHAIN COMPOUNDS

Mirror-image Isomerism.—As regards their mirror-image isomerism, open-chain compounds may be considered according to the number of carbon atoms that their molecules contain. Dissymmetric compounds with *one* or *two carbon atoms* in the molecule suitable for resolution are not easy to obtain, and it was not until 1913 that a one-carbon compound—bromoiodomethanesulphonic acid, $CHBrI{\cdot}SO_3H$—was satisfactorily resolved (Pope and Read). It proved to be optically stable. Among the compounds with *three carbon atoms* in the molecule are the

biochemically important substances, lactic acid and the α-amino-acids, alanine, serine and cystine. The configuration of the group $-H_2C-HCX-CO_2H(X=OH$ or $NH_2)$ seems to be the same in the naturally occurring optically active forms of these substances. The compounds containing *four carbon atoms* in the molecule include the tartaric acids which played so important a part in the establishment of the fundamental principles of stereochemistry. Their structure having been fixed as dihydroxy-succinic acids, the tetrahedral theory enabled a precise form to be given to their molecular dissymmetry envisaged by Pasteur; *d*- and *l*-tartaric acids will have the enantiomorphous configurations shown in fig. 7 which can also be conveniently indicated by the projection formulae shown on the right. It will probably only be possible to determine which of these configurations corresponds with which antimer when a method has been discovered of calculating the optical rotation of a dissymmetric compound from some measurable property, such as the refractivity, of the radicals *a*, *b*, *c*, *d*, associated with the asymmetric carbon atom.

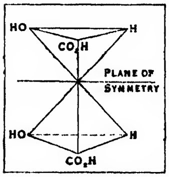

FIG. 8.—THIRD POSSIBLE, OR CIS-, CONFIGURATION OF TARTARIC ACID MOLECULE PLANE OF SYMMETRY

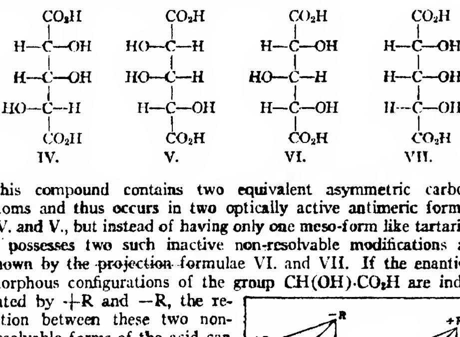
Besides the two configurations of the tartaric acid molecule shown above, a third, represented in fig. 8, is also possible. This configuration has a *plane of symmetry*, as indicated, and is therefore superposable upon its mirror-image and is incapable of optical activity. This inactive, non-resolvable form of tartaric acid was discovered by Pasteur, who obtained it by the action of heat on salts of tartaric acid, and is known as *mesotartaric acid*. The existence of this form is determined by the structural identity of the two halves of the tartaric acid molecule. The acid contains two equivalent asymmetric carbon atoms, and the relation between its *d*-, *l*-, and *meso*-modification can be represented by the symbols +A+A, −A−A, and +A−A. Every compound containing two equivalent asymmetric carbon atoms must be capable of existence in three such forms and generally in a racemic form.

In the *five-carbon series* a new stereochemical feature is exhibited in trihydroxyglutaric acid (IV.–VII.).



IV. V. VI. VII.

This compound contains two equivalent asymmetric carbon atoms and thus occurs in two optically active antimeric forms, IV. and V., but instead of having only one meso-form like tartaric, it possesses two such inactive non-resolvable modifications as shown by the projection formulae VI. and VII. If the enantiomorphous configurations of the group $CH(OH){\cdot}CO_2H$ are indicated by +R and −R, the relation between these two non-resolvable forms of the acid can also be represented as in fig. 9.

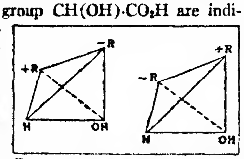


FIG. 9.—NON-RESOLVABLE MODIFICATIONS OF TRIHYDROXYGLUTARIC ACID

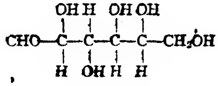
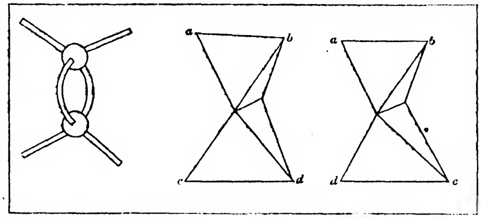
The *six-carbon series* contains the sugars glucose and fructose and their stereoisomers, and it is in this group of compounds that the usefulness of the conception of the asymmetric carbon atoms has been most strikingly demonstrated. The hydroxy-aldehydic formula for glucose



contains four non-equivalent asymmetric carbon atoms. Since the introduction of a new asymmetric carbon atom into a compound doubles the number of stereoisomerides previously possible, a compound containing *n* non-equivalent asymmetric carbon atoms should exist in 2^n forms. The number of possible stereoisomers of the same structure as glucose is therefore sixteen; in other words, there should be eight stereoisomeric aldohexoses,



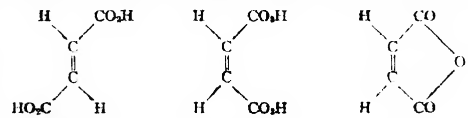
FIGS. 10. 11. 12.—TETRAHEDRAL DISTRIBUTION OF VALENCIES OF TWO DOUBLY LINKED CARBON ATOMS

each existing in two antimeric forms. All the eight are known, many of them in both antimeric forms, and their configurations have all been determined. (*See* CARBOHYDRATES.) It is unnecessary to proceed further with the consideration of open-chain compounds as the study of the more complex series has not brought new principles to light.

Geometrical Isomerism.—On the tetrahedral hypothesis two doubly linked carbon atoms will be represented by models such as those shown in fig. 10 or figs. 11 and 12.

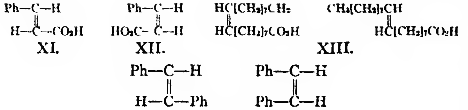
Van't Hoff pointed out in his original brochure that this view of the ethylenic linking leads to two conclusions: (1) That there should be no free rotation about an ethylenic linking; the molecule should possess two equilibrium configurations as indicated by figs. 11 and 12. Ethylenic compounds should therefore exist in stereoisomeric forms, except when the radicals *a* and *b* (or *c* and *d*) are identical; (2) That the doubly linked carbon atoms and the four radicals *a*, *b*, *c*, *d* all lie in one plane. This plane is then a plane of symmetry, and thus ethylenic compounds, even when of the type , should be incapable of exhibiting optical activity.

These conclusions are fully confirmed by experiment. A large number of ethylenic compounds of the requisite structural type have been found to exist in two isomeric forms, and no adequate explanation has been found for this isomerism except the *cis-trans isomerism* determined by this conception of the ethylenic linking; also no case of optical activity determined by the non-planar configuration of the complex  has been established. The best known example of cis-trans isomerism is that presented by fumaric and maleic acids. These acids are structurally identical; each of them is an ethylenedicarboxylic acid of the structure $HO_2C{\cdot}CH{:}CH{\cdot}CO_2H$. The great difference in properties which they exhibit can only be due to difference in configuration. Maleic acid, which readily forms a cyclic anhy-



VIII. Fumaric acid IX. Maleic acid X. Maleic anhydride

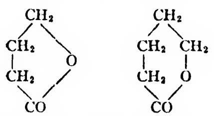
dride X., and is regenerated from it by addition of water, must have the cis-configuration IX. Fumaric acid consequently has the trans-configuration VIII. Other examples of cis-trans isomers are cinnamic, XI., and allocinnamic acids, XII., oleic and elaidic acids, XIII., and stilbene and isostilbene, XIV.



XI. XII. XIII. XIV.

STEREOCHEMISTRY OF CYCLIC COMPOUNDS

Ring Formation.—An overwhelming proportion of the known cyclic compounds contain five- or six-numbered rings The special tendency to the formation of such rings, thus indicated, is well illustrated by the hydroxy-acids of the general formula $HO(CH_2)_nCO_2H$ When $n=3$ or 4, but only then, these acids lose water spontaneously, forming cyclic internal esters (lactones) of the structure



Such ring formation can thus only occur when a 5- or 6-membered compound will be formed

It is possible to form three- and four-membered rings, but they tend to spring open under the influence of reagents, the tendency being more marked in the 3- than in the 4-rings. Thus ethylene, XV, which we can regard as a 2-ring, cyclopropane, XVI, and cyclobutane, XVII, form a series of diminishing unsaturation

XV. XV.a XVI. XVI.a XVII. XVII a

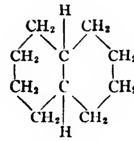
For ethylene combines with all the halogens, even with iodine, when ethylene di-iodide XV.a is formed; cyclopropane, XVI., is stable towards iodine but reacts with bromine in the cold, forming trimethylene dibromide; cyclobutane, XVII, is not opened by bromine, but is converted by catalytic reduction with hydrogen (under conditions under which cyclopentane and cyclohexane are perfectly stable) into *n*-butane, XVII a.

These facts constitute a striking confirmation of the tetrahedral theory, for the angle at which the axes of a regular tetrahedron are inclined to one another is 109° 28′, and this is very nearly the same as the angle between adjacent sides of the regular pentagon (108°) Thus we have an immediate explanation of the ready formation of 5-membered carbon rings; in them the valencies linking each carbon atom to its neighbour on either side are inclined at an angle which hardly differs from the natural angle between carbon valencies In cyclobutane, however, the angle of deflection of the valencies from their natural inclination, $\frac{1}{2}$ (109° 28′—90°)=9° 44′, is considerable; in cyclopropane it is larger, $\frac{1}{2}$(109° 28′—60°)=24° 44′; whilst in ethylene it amounts to 54° 44′.

This theory correlating the relative instability of 3- and 4-rings with the strain due to deflection of the valencies from their natural directions is known as *Baeyer's Strain Theory* (1885). In six- and higher-membered rings there is apparently no strain; the strain is relieved by buckling of the ring Thus cyclohexane may have either of the strain free arrangements

FIG 13 —BUCKLING OF SIX-MEMBER RINGS TO RELIEVE STRAIN

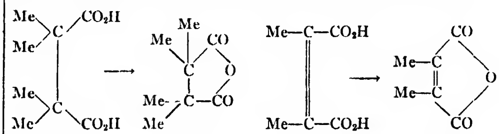
Such non-planar configurations, if sufficiently permanent, should cause molecular dissymmetry in appropriate derivatives. It has been impossible to demonstrate this dissymmetry; hence the molecules of these buckled rings are probably in a state of flux between their various possible configurations on account of their thermal agitation. Convincing evidence of the non-planar configuration of the cyclohexane ring is however supplied by the discovery (Hückel, *Annalen,* 1925, 441, 1) that decahydronaphthalene, XVIII, can exist in a trans- as well as in a cis-modification, for if the two cyclohexane rings in this compound were plane



XVIII.

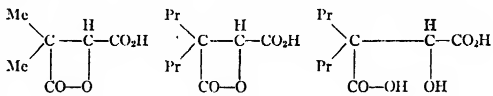
the cis-form would alone be possible.

Substitution has a remarkable effect in promoting ring closure. Thus tetramethylsuccinic acid, XIX, passes into its cyclic anhydride, XX, with far greater readiness than succinic acid itself,



XIX. XX. XXI. XXII.

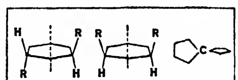
and dimethylmaleic acid, XXI, shows so great a tendency to ring-closure that when liberated from its salts it passes spontaneously into its anhydride, XXII The larger the substituent the greater seems to be its effect. Thus the dimethyl-lactone, XXIII, can only be produced indirectly, and once opened it cannot be re-formed, but the analogous dipropyl-lactone, XXIV, is formed spontaneously from the corresponding hydroxy-acid, XXV..—



XXIII. XXIV. XXV

It has long been held probable that the regular tetrahedral configuration obtains only in a carbon atom attached to four like radicals, as in methane or carbon tetrachloride, and that when the radicals are not all alike the angles between the valencies may be rendered unequal Further, if the angle between one pair of valencies is increased by the space demands or the mutual repulsion of the two attached radicals, the angle between the other pair may suffer a correlated decrease Many facts have been accumulated by Thorpe and Ingold which can be interpreted as supporting the view that enhanced tendency to ring closure may arise from such modifications of the natural valency angle

Geometrical Isomerism.—Since freedom of rotation about single linkings is abolished by ring-closure, geometrical isomerism is of frequent occurrence among cyclic compounds. Thus any disubstituted polymethylene (in which the substituents are on different carbon atoms) may exist in a *cis*- and a *trans*-form as the accompanying diagrams of a *cis*- and *trans*-1-3-disubstituted cyclohexane show.



FIGS. 14 & 15 —CIS- AND TRANS- 1-3 DISUBSTITUTED CYCLOHEXANE. FIG. 16.—DOUBLE FIVE MEMBERED RINGS

Where, as in the compound represented, the two substituents are alike, the molecule of the *cis*-form has a plane of symmetry (the perpendicular plane through the dotted line in fig 15) and this modification is therefore non-resolvable into optical antipodes; the molecule of the *trans*-form has, however, only an axis of symmetry (the dotted line in fig. 14); it is therefore dissymmetric, and this modification can thus exist in optically active forms. This difference between cis- and trans-modifications provides a very reliable method for determining configuration in those cases (as in many cyclo-paraffin carboxylic acids) where it is applicable.

The phenomena presented by cyclic compounds have a most important bearing on the spatial distribution of the carbon valencies. For whilst *any* non-planar configuration would account for the observed relationship between molecular dissymmetry

and structure, and for the isomerism due to the combinations of centres of asymmetry, the relative stability and readiness of formation of 5-membered rings proves that the natural angle between two of the carbon valencies must be close to 108° (the angle of the regular pentagon). Since, further, spirocyclic compounds of the double 5-ring type are formed with great readiness it would appear that the angle between the other two valencies

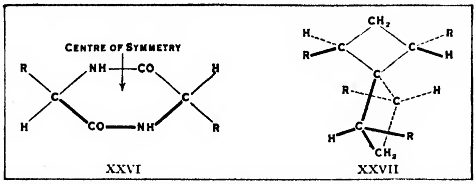


FIG. 17.—EXAMPLES OF MOLECULES WITH A CENTER OF SYMMETRY AND WITH AN ALTERNATING AXIS OF SYMMETRY

also approximates to 108°. The chemistry of cyclic carbon compounds thus strongly indicates the regular tetrahedral arrangement in which the intervalency angle is 109·5°.

Mirror-image Isomerism.—The conception of the asymmetric carbon atom, which in the open-chain series provides such a ready means of recognising molecular dissymmetry, is much less useful when applied to cyclic compounds. In cyclic compounds molecular dissymmetry is most easily recognised by noting the absence of centre, alternating axis and planes of symmetry from the tridimensional formula, for a molecule must possess at least one such element of symmetry to have the property of superposability upon the mirror-image. Examples of molecules with a *plane of symmetry* have already been given. Well known examples of molecules with a *centre of symmetry* are those of the trans-forms of the cyclic anhydrides of the α-amino-acids, XXVI. (fig. 17). The *alternating axis of symmetry* has not yet acquired practical importance in stereochemistry, since no compounds with a molecule having an alternating axis but no plane or centre of symmetry are known; one of the simplest examples would be a compound of the type XXVII.

Among the cyclic compounds possessing special stereochemical interest are methylcyclohexylideneacetic acid, XXVIII. (fig. 18), resolved by Perkin, Pope and Wallach (*J. Chem. Soc.*, 1909, *95*, 1789) and the naturally occurring *d*- and *l*-inositols. The latter are cyclic hexahydric alcohols of the structure

$$\mathrm{CH{\cdot}OH}\begin{matrix}\diagup \mathrm{CH(OH){\cdot}CH(OH)} \diagdown \\ \diagdown \mathrm{CH(OH){\cdot}CH(OH)} \diagup\end{matrix}\mathrm{CH{\cdot}OH},$$

and although there are 7 geometrical isomers of this formula, the configuration of the active forms can be deduced because only

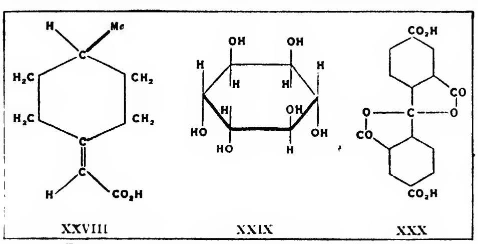

FIG. 18.—CONFIGURATIONS OF CYCLIC COMPOUNDS

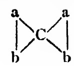
one of the isomers (that of which XXIX. represents one of the antimeric components) is molecularly dissymmetric.

The ketodilactone of benzophenonetetracarboxylic acid, XXX., resolved by Mills and Nodder (1921) is of the type



Its optical activity demonstrates the molecular dissymmetry that on the tetrahedral theory such spirocyclic compounds, in spite of the symmetry of their structural formulae, should possess. They have an axis of symmetry and the two forms correspond with the right- and left-handed forms of a two-bladed screw-propeller.

STEREOCHEMISTRY OF ELEMENTS OTHER THAN CARBON

4-Covalent Elements.—In all optically active compounds known up to 1899 the molecular dissymmetry was dependent upon the spatial arrangement of the valencies of carbon. In that year a great advance was made through the discovery by Pope and Peachey that quaternary ammonium salts of the type $N(R_1R_2R_3R_4)X$ could be resolved into optical antipodes, for this indicated that the valency configurations of other elements besides carbon could have sufficient permanence to make their stereochemical investigation possible, and thus a wide field of research was opened. Further work on quaternary ammonium salts showed, (1) that molecular dissymmetry could no longer be demonstrated when two of the hydrocarbon radicals were identical, proving that the ion $(NR_1R_2R_3R_3)$ has a plane of symmetry; (2) that different methods of formation of a given salt, such as

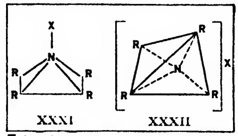


FIG. 19.—PYRAMIDAL AND TETRAHEDRAL CONFIGURATIONS FOR AMINE SALTS

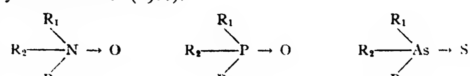
$$NR_1R_2R_3+R_4X \rightarrow NR_1R_2R_3R_4X \leftarrow NR_2R_3R_4+R_1X$$

never yielded isomeric modifications, indicating that the valencies linking the four hydrocarbon radicals to the nitrogen atom are inter-equivalent. Only two configurations of the ammonium ion satisfy these conditions, namely, the pyramidal configuration XXXI. (fig. 19) and the tetrahedral configuration XXXII., and of these the first has been definitely disproved by showing that a spirocyclic ammonium salt of the type XXXIII. (fig. 20) can be resolved into optically active components; for it can easily be seen that, if the two rings in this compound were attached to the base of a square pyramid, the molecule would have a plane of symmetry and the compound would be non-resolvable. In the ammonium ion the nitrogen atom must accordingly have the tetrahedral configuration XXXII. corresponding with the asymmetric configuration XXXIV. of its spirocyclic derivative XXXIII.

The amine-oxides are another class of compounds of 4-covalent nitrogen (*see* VALENCY), and in these also the radicals are tetrahedrally disposed about the nitrogen atom, for amine-oxides of the type XXXV. have been obtained in optically active forms by Meisenheimer (1908).



XXXV. XXXVI. XXXVII.

Phosphorus and arsenic have also been shown to have the tetrahedral configuration when in the 4-covalent state—phosphorus

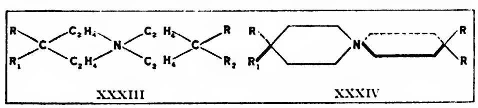


FIG. 20.—SPIROCYCLIC AMMONIUM DERIVATIVE AND ITS ASYMMETRIC CONFIGURATION

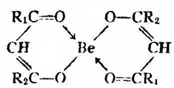
through the optical activity of a phosphine-oxide, XXXVI. (Meisenheimer and Lichtenstadt, 1911), and arsenic through that of an arsine-sulphide, XXXVII. (Mills and Raper, 1925). In the first short period (*see* PERIODIC LAW), besides carbon and nitrogen, the elements beryllium, boron and oxygen can assume the 4-covalent state, and there is evidence that the atoms of each of these elements then have the four radicals tetrahedrally disposed about them. This was proved for beryllium by the pro-

duction of an optically active compound of the type

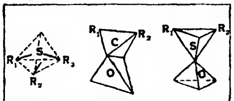


(Mills and Gotts, 1926), and for boron in a similar way by Böeseken and Meulenhoff (1924), and the tetrahedral symmetry of 4-covalent oxygen is indicated by the work of Morgan and Bragg on basic beryllium acetate (1923) The molecular dissymmetry of silicon compounds of the type $SiR_1R_2R_3R_4$ has been established by Kipping, and the investigation of the configuration of 4-covalent copper and zinc by the method used for 4-covalent beryllium has shown that their valencies are also tetrahedrally distributed

It thus appears to be the rule that when an atom is linked directly to four other atoms these are arranged around it tetrahedrally. This rule is however not universal: thus, many compounds of 4-covalent platinum containing a complex of the type $[PtA_2B_2]$ occur in two, evidently stereoisomeric, modifications. A and B may be chemically similar, as ammonia and ethylamine, the complex then being a bivalent ion, or chemically diverse, as pyridine and chlorine, when the complex is electrically neutral. This isomerism is clearly incompatible with a tetrahedral arrangement of the radicals about the platinum atom and is to be explained most simply by supposing that 4-covalent platinum has a plane configuration and that the isomers are cis- and trans-modifications of the type

3-Covalent Elements.—The stereochemical relationships of 3-co-ordinated elements are clearest in the case of sulphur Sulphonium salts $[SR_1R_2R_3]X$, in which three groups are covalently linked to the sulphur atom, were shown to be molecularly dissymmetric by Pope and by Smiles (1900); the sulphonium ion therefore has a non-planar configuration (fig 21).

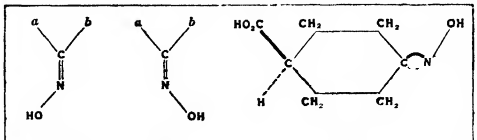
Other compounds of 3-covalent sulphur are the sulphinic esters, $R{\cdot}S{\lt}^{O}_{OEt}$, the sulphoxides, $^{R}_{R}{\gt}S{\rightarrow}O$, and the sulphilimines, $^{R}_{R}{\gt}S{\rightarrow}NR$, and these have each been shown to have a similar non-planar configuration, since optically active representatives of the three classes have been obtained, principally by Phillips and Kenyon (1925–27) The sulphoxides therefore differ from the ketones in configuration, probably as shown in diagrams which are given in fig 21, the difference assumed in the oxygen linking is indicated by the electronic theory of valency and is confirmed by the parachor (*q v*) Optically active selenonium salts were obtained by Pope and Neville (1902), hence 3-covalent selenium also has a non-planar configuration



XXXVIII XXXIX XL

FIG 21—NON-PLANAR CONFIGURATIONS FOR 3-COVALENT ELEMENTS

The configuration of the trivalent nitrogen atom is of special interest on account of the number and importance of the compounds in which the element is present in this state. The numerous attempts made to obtain optically active compounds of the type $NR_1R_2R_3$ have all given negative results, but it is scarcely safe to conclude from this that these compounds have a planar configuration, for it is possible that they are non-planar but racemize rapidly, and the configuration of this important type is still an open question. However, in compounds of trivalent nitrogen of the type —X:N·Y—, where the nitrogen atom is directly linked to two other atoms only, and therefore to one of them by a double bond, the evidence for the non-planar disposition of its valencies is quite definite Thus, oximes of the type $^{a}_{b}{\gt}C{:}NOH$ can generally be prepared in two isomeric modifications, and as the isomerism is repeated in the *O*-methyl ethers, for which only one structure $^{a}_{b}{\gt}C{:}NOMe$ is possible, it must be determined by a difference of configuration The form of the group $^{a}_{b}{\gt}C.N$ being fixed by the well-established tetrahedral arrangement of the carbon valencies, a configurational difference can only be produced by a lateral displacement of the hydroxyl group to bring it nearer to one of the groups *a* or *b*, as indicated by the diagrams (fig 22), and this requires a non-planar disposition of the nitrogen valencies



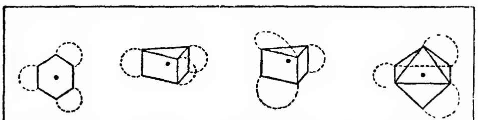
XLI*a* XLI*b* XLII

FIG. 22—POSSIBLE DISPOSITIONS OF CYANIDE RADICALS

This view, due to Hantzsch and Werner (1890), is confirmed, (1) by the course in the two isomerides of an intra-molecular transformation brought about by acids (*Beckmann transformation*) in which one of the two groups *a* or *b* changes places with the hydroxyl group, for if *a* is thus transposed in the one modification then *b* is transposed in the other, and (2) by the optical activity of the cyclic oxime, demonstrated by Mills and Bain (1910), since the molecule of this compound can only be dissymmetric if the nitrogen valencies do not lie in one plane

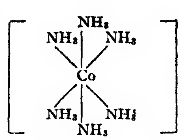
6-Covalent Elements.—Werner's proof that substances like the compounds of metallic salts with ammonia, formerly regarded as "molecular compounds," are co-ordination compounds in which a certain number of atoms or groups, most frequently six, are directly attached to the metallic atom ($CoCl_3{\cdot}6NH_3$, for example, having the constitution XLVI.) brought with it the problem of determining how these six groups are disposed about the central atom. If it is assumed that the valencies by which they are attached are inter-equivalent (and this is supported by the absence of the isomerism which should otherwise occur), three arrangements are possible· the plane hexagonal, the prismatic, and the octahedral (fig. 23).

A decision between these was obtained by investigating the compounds formed by linking the co-ordination positions together in pairs through 4-membered chains, as can be done, for example,

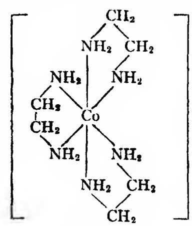


XLIII XLIV*a* XLIV*b* XLV

FIG. 23.—FOUR POSSIBLE CONFIGURATIONS OF 6-COVALENT ELEMENTS



XLVI



XLVII

by the three-fold replacement of two co-ordinated ammonia molecules by one of ethylenediamine (or of two nitrito-groups by an oxalato-group), so as to produce a complex in which the metallic atom forms a common member of three symmetrical 5-membered rings, XLVII. Since it is evident that only adjacent co-ordination positions can be bridged in this way, the possible configurations for the tricyclic complex are those indicated by the dotted lines in the four different diagrams which are given in fig. 23, and of these the three first are evidently symmetrical and only the last is dissymmetrical, for it possesses only a (trigonal) axis of symmetry. Experimental investigation of the salts of these tricyclic ions has shown that they can be produced in optically active forms. The ions are thus dissymmetric and must consequently have the last configuration. It is therefore to be concluded that in such compounds the six covalencies of the central metallic atom are octahedrally disposed.

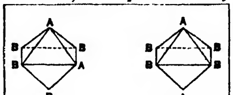


FIG. 24.—OCTAHEDRAL ISOMERS (A) CIS- AND (B) TRANS-

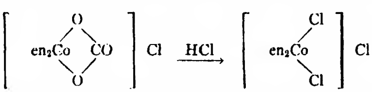
This conclusion is confirmed by the phenomena of geometrical isomerism shown by complexes of the type $[MA_2B_4]$, such as are contained in the diacidotetrammine salts of cobalt and chromium. These compounds should exist in three isomeric forms if their configuration is hexagonal or prismatic, but in two only if it is octahedral, the alternative arrangements then being those in which the two groups A lie at the ends, (1) of an edge (*cis*-compound), and (2) of a diagonal (*trans*-compound) of the octahedron, and the number of isomers actually found is two. Moreover, in dicyclic derivatives of this type like $[en_2CoCl_2]Cl$ ($en = NH_2 \cdot CH_2 \cdot CH_2 \cdot NH_2$), that isomer for which the *cis*-configuration is indicated by its formation from a tricyclic compound



can be obtained optically active, whilst the other, the *trans*-isómer, cannot be resolved in accordance with the following tri-dimensional formulae, fig. 25, which show the symmetry, on the octahedral representation, of the *trans*- and the dissymmetry of the *cis*-form.

The general result of the stereochemical investigation of the elements has thus been to show that as a rule the valencies of an atom are disposed in space as symmetrically as possible, so that, for example, a 4-covalent atom has the four directly attached atoms arranged tetrahedrally about it, and the six atoms linked to a 6-covalent atom are grouped round it octahedrally; but it has also shown that there are well-marked exceptions to this rule, the most notable being the probable square arrangement of the four groups about 4-covalent platinum and the non-planar disposition of the valencies of 3-covalent sulphur. (W. H. MI.)

STEREOCOMPARATOR, an instrument for comparing two astronomical photographs of the same star-field, commonly combined with a Blink-microscope (*q.v.*).

STEREOPHOTOGRAMMETRY. In the earliest applications of photography to surveying, use was made of various simple graphical constructions or calculations in order to determine bearings and angles of elevation or depression from the camera station. In order to simplify these constructions or calculations, the photograph was usually exposed in a vertical plane. Two photographs, taken from the ends of a known base and treated in this manner, thus enabled a complete survey to be made of all visible ground in the area common to the pair. The necessity for avoiding acute graphical intersections in the fixing of points usually meant a long base, with a resulting difficulty in the identification of corresponding features in the two widely dissimilar views. The next step was consequently to return to a comparatively short base and at the same time to eliminate the indetermination of acute graphical intersection by the parallactic measurement of distances.

The Stereocomparator.—The first practical application of this method appears to have been in the stereocomparator of Tourcade in 1900. The two photographs were taken in the same vertical plane, although not necessarily at the same height, and were of course placed in the same plane in the comparator. Bearings and elevations were still calculated from the photo-co-ordinates of points on one of the pictures, while the distances from the base were calculated from a stereoscopic measure of parallax. The latter was effected by a lateral shift of one plate relative to the other, until the stereoscopically reconstructed image of the setting feature appeared to lie at the same distance from the observer as the fused image of a pair of floating marks contained in the eye-pieces of a binocular microscope used for the examination of the plates.

The stereocomparator has had an extensive application in the past, and is even now directly applied in one modern method of survey from vertical air photographs. From the practical point of view, however, its initial use suffered from two serious drawbacks, in that it required the computation of space co-ordinates from independent measurements, and that it implied a system of point by point plotting. (See also BINOCULAR INSTRUMENT: *The Stereoscope*.)

The Thompson Stereoplotter.—The first of these disadvantages was overcome in the 1908 model of the Thompson stereoplotter, which may consequently be considered as the first example of the true plotting machine. It employed the stereocomparator principle without modification, but by the addition of a lever system.

The Stereoautograph.—The disadvantage of point by point plotting remained in the Thompson machine and was overcome by the von Orel stereoautograph of 1909–11. It is interesting to note, however, that Thompson in 1908 had in view the construction of an automatic machine called the "stereoplanigraph." This would no doubt have been on the same general lines as the stereoautograph had it reached maturity. The stereocomparator is again used in the von Orel machine, but the plotting system is based on intersections from the ends of the base rather than on an explicit measure of distances. Reduced to its lowest terms, it consists of two azimuth levers which are coupled to the lateral shift of the two plates. This simple arrangement would, however, introduce mechanical difficulties in the carriage of a drawing pencil at the variable intersection of the two levers, and in the necessity for shifting the pivots of these levers in accordance with variations in base length.

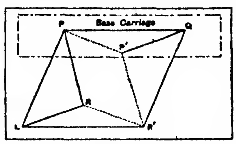

FIG. 1

Suppose, in the first alternative, that LP, RP (fig. 1) were the azimuth levers; P being the plotted point and LR the base. Then if any two parallelograms LPQR', RPP'R' are drawn on the rays LP, RP with a common corner at R', it is clear that P'Q will be equal in magnitude and direction to the base LR, and that LP, R'P' will still represent the true directions of the azimuth levers. Consequently L, R' may represent two *fixed* pivots of the azimuth levers, if the base QP' is set inwards in magnitude and direction from a length PQ equal and parallel to LR'. Moreover the base carriage PP'Q may be moved anywhere parallel to itself by alteration in the lengths and directions of the azimuth levers LP, R'P'. The point P will always represent the position of the plotted point relative to L as left hand camera station. Similarly, P' will always represent the position of the plotted point relative to R' as right-hand camera station. Lastly, the actual drawing

pencil will trace a similar plot if it is placed in any fixed position relative to P or P′. It may consequently be rigidly attached anywhere to the base carriage. This simple principle, due originally to von Orel, is sometimes known as the *zeiss parallelogram,* and has been elaborated into several different types. These different types, which find an application in the later plotting machines, are all comprised in the fact that any or all of the three co-ordinates

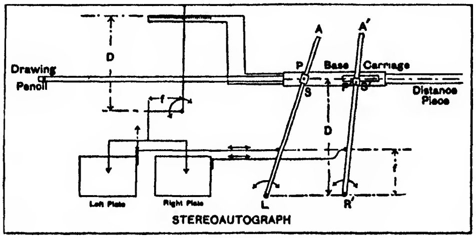

FIG. 2

of one end of the base relative to the other end may be set at any of the corners of the initial parallelogram LPQR′—a statement which is evident from the simplest geometrical considerations

A diagram of the action of the stereoautograph is given in fig 2 The azimuth control shifts the carriage of *both* plates, and consequently rotates the two azimuth levers AA′ by an equivalent amount These levers slide in sleeves SS′ attached to pivots on the base carriage, which is thus moved freely along the distance piece The sleeve pivots, PP′ correspond to the points PP′ of fig. 1, the base setting being effected on the pivot P′. The distance control moves the distance piece bodily, and parallel to itself, towards or away from the line of pivots LR′ of the azimuth levers. In consequence, the base carriage slides down the left azimuth arm, rotating the right azimuth arm in the process and thus shifting the right-hand plate relative to the left on an upper slide. The parallactic separation of corresponding points is thus altered, so that the floating marks appear successively in stereoscopic coincidence with points whose distance from the base corresponds to the setting of the distance piece. This is of course the unmodified principle of the stereocomparator. The height system is essentially the same as in the Thompson machine, the height scale being carried on an extension of the distance piece

By combining the movements of the three controls, the apparent movements of the floating mark can be made to follow along the detail of the reconstructed stereoscopic image, the plan of which is thus drawn automatically by a pencil attached to the base carriage. By clamping the height lever to the distance piece, the machine loses a degree of freedom If then the distance and azimuth controls are moved so that the floating mark still appears to travel along the surface of the ground, the pencil will trace the contour corresponding to the height at which the height lever is clamped

The stereoautograph is capable of fast automatic plotting, provided that the plates are exposed in the *same vertical plane.* The whole principle of the stereocomparator as a means of determining horizontal distances from a measure of simple parallax otherwise breaks down Moreover, if the plates are inclined, vertical lines in nature will no longer appear parallel on the photograph, but will converge to the plumb point as vanishing point. The system of plotting azimuths in these early machines, however, obviously requires the image of vertical lines to be parallel, in order that the horizontal distances between points on the plate may be independent of the heights of such points.

Before long, it became essential on the score of accuracy, convenience and economy to expose inclined plates on converging orientations. Even in mountainous country, where photographic survey had hitherto found its exclusive application, it was often desirable to site the cameras on high ground in order to minimize the extent of dead ground not covered stereoscopically The camera axes had consequently to be depressed in order to include as wide a field as possible. With the World War period of improvements in photography from the air, it became economically possible to survey *flat* country photographically, with the corresponding necessity for exposing horizontal rather than vertical plates. Further, in the case of air photographs, it is as yet impossible so to stabilize the camera or the aeroplane as to ensure that the two plates are exposed in the same plane at all, at any rate to the degree of precision attainable by deliberate exposure on the ground.

It may in fact be assumed that any type of country can be surveyed photographically provided that, in order to secure the best results, it can be photographed on a plate parallel to its mean slope. Precipitous mountain slopes require vertical, and dead flat plains horizontal plates Between these two extremes there will be a particular tilt for the most efficient survey of a particular type of country, and a corresponding height of station in order to secure the necessary photographic field. The development of air photography has allowed this ideal to be approached, with the consequent demand for a plotting machine with a "universal" range in permissible orientations in space of the camera axes.

The stereoautograph can, as a geometrical proposition, be adapted by certain variations in its plotting mechanism to deal with inclined or converging photographs *See* O. von Gruber, "Der von Orel-Zeiss'sche Stereoautograph mit Zusatzeinrichtung zur Ausarbeitung von Luftaufnahmen," in *Internationales Archiv fur Photogrammetrie* (Vienna, 1923); but a different base setting is in general necessary for each contour Moreover, corresponding points on the two photographs will, generally speaking, no longer lie at the same distance from the eye base when the photographs are placed in the same plane in the comparator, by reason of the perspective distortion due to tilt. A restricted range in tilt can in these circumstances be tolerated by the eyes without a breakdown of stereoscopic fusion, but the process cannot be continued indefinitely, even if a complicated transverse shift of the plates were introduced

The Photogoniometer.—Attempts were accordingly next made to extend the range of plotting machines by the incorporation of the Porro-Koppe photogoniometer, which uses a theodolite to measure horizontal and vertical angles from a photograph The photograph is mounted in the plate carrier in relation to a photographic objective, which is in all respects similar to the camera objective, so that the internal perspective conditions are reproduced correctly. This implies two transverse adjustments in the plane of the photograph and a fine focussing rack as the first essentials in design. The external perspective conditions are then re-established by tilting the whole camera body similarly to the field camera at exposure This implies the possibility of tilting about a horizontal axis in order to set for the magnitude of tilt, and of rotating the photograph in its own plane about the plate perpendicular in order to set for the direction of tilt. Horizontal and vertical angles as from the camera station may then be measured by means of a theodolite whose horizontal and vertical axes are arranged to intersect in or near the centre of the exit pupil of the objective.

Where the photogoniometer is employed as an auxiliary in a plotting machine, rotation in azimuth is usually given to the camera body, while rotation in altitude only is furnished by the telescope of the theodolite In this form the photogoniometer is mechanically unsuitable for photographs whose axes are vertical or tilted less than about 45° from the vertical; *i.e.*, for the majority of air photographs. Where the instrument is used independently, however, there is no need to accept this limitation Both altitude and azimuth rotations may, for instance, be imparted to the telescope, leaving the camera body adjustable for tilt only; or, in order to avoid moving the eye into impossible positions where the camera axis approaches the vertical, the altitude movement may be furnished by the rotation of a prism in front of the telescope objective.

Intersection Photogoniometric Machines.—The first plotting machine to employ the photogoniometer principle was the

Hugershoff *autocartograph*, the photographs being observed through the goniometer lenses by a binocular telescope. The autocartograph is designed for high obliques, and there is difficulty in dealing with vertical (axis) air photographs, or indeed with any photographs where the camera axis is tilted less than about 45° from the vertical. This is a direct consequence of the design of the photogoniometers, as mentioned above. Moreover the

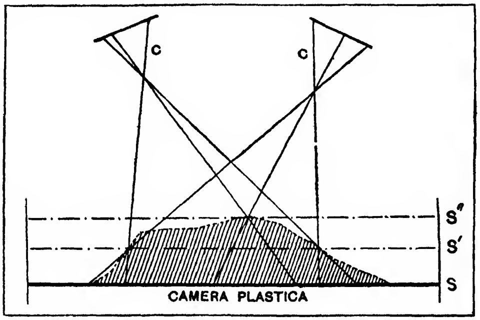

FIG. 3

azimuth levers would need to be capable of all round rotation, and the von Orel plotting system is clearly unsuited to this possibility. It is true that the height and distance controls of the auxiliary drum plot can be interchanged, with the result that an elevation instead of a plan can be drawn on the drum. Consequently, if a pair of vertical (axis) photographs are placed in the position of horizontal (axis) photographs in the goniometers, it is possible to draw a direct plan from them on the drum.

The Camera Plastica.—Concurrently with the intersection photogoniometric type, various efforts have been made to develop machines to deal primarily with air photographs on the principle of the *camera plastica*. The latter, usually attributed to Scheimpflug, is shown diagrammatically in fig. 3. Two projection cameras CC are set in the same relation to one another in the scale of the plot as the two positions of the air camera at exposure, and throw real images on a movable screen S representing the ground plane of reference. It is clear that if the screen is moved bodily towards the projection cameras (to S′ or S″) until the coincidence of corresponding images is obtained, this coincident image will represent the true plan position of the point considered, the position of the screen at the same time affording a measure of heights. Coincidence may be estimated by a flicker system which enables the two images to be thrown on the screen alternately in rapid succession, or a stereoscopic image in anaglyphic relief may be obtained by projecting in two colours and viewing through filters of the same colours. In the latter case plotting may be effected according to the movements of a real floating mark in the plane of the screen, the depth movement being effected by bodily translation of the screen towards the projection cameras.

Many applications of this principle have appeared on the market, the best known being perhaps the Nistri *photocartograph*. In this case the two projection cameras are set by trial on control point screens. In order to preserve true perspective conditions the projection lenses are set at the principal distance of the air camera from the photographs, and must consequently be of shorter focus in order to form sharp images on the screen. Coincidence plotting is effected on the flicker system, the movements of a steel pointer over the screen being copied by a pantograph.

The inception of this type of machine was no doubt due to the fact that the whole photograph is seen at once, and that in consequence the systematic trial setting of air photographs on control points is much easier. Up to the present no fully economic method of determining independently the plate constants of the air photograph has been discovered, and the computed or trial setting of photogoniometric machines is apt to be protracted. On the other hand the camera plastica type depends on depth of focus on the plotting screen, and the introduction of considerable tilts and variations in relief is apt to strain this factor beyond its limits of endurance, particularly as the use of a small stop is for various reasons undesirable. With automatic focussing devices and the use of rectified photographs, the range of the camera plastica might possibly be extended.

The Zeiss Stereoplanigraph.—This difficulty of preserving focus during movements of the plotting plane has been successfully overcome in the Zeiss stereoplanigraph which works on the same general principle as the camera plastica, by the introduction of an auxiliary tele-objective of variable focus. In this machine two projection cameras are fixed on a cross slide, the internal and external perspective conditions at exposure being reproduced by setting in exactly the same way as for the photogoniometers of the autocartograph. The rear nodes of the projection camera objectives form a Zeiss parallelogram with the two floating marks, any of the corners of which are thus available for setting the magnitude and direction of the base. Actually the projected length of the base is set inwards on the floating marks, while the remaining two co-ordinates defining the orientation of the base in space are set one on each of the camera units. The object of this arrangement is to provide room for the two camera units without an excessive increase in their distance from the floating marks (this being one of the disadvantages of the simple camera plastica), and at the same time to avoid superimposing the two images on a single floating mark, with the consequent necessity for visual separation by colour filters.

The distance and height plotting movements are operative on the cross slide carrying the two camera units, while the direction movement is effected by a lateral shift of the two floating marks together in the direction of the line joining them. The distance and direction, or alternatively height and direction, plotting movements are coupled through gearing to a drawing pencil. This possibility of interchanging the distance and height controls enables direct plotting to be carried out either in plan or in elevation, so that it is possible to deal equally well with horizontal, vertical, or intermediately tilted photographs. In order to preserve focus on the plane of the floating marks, an auxiliary lens system, consisting of bi-convex and bi-concave lenses of equal power, is supported in front of the camera objective, the rear node of the combination coinciding approximately with the rear node of the camera objective. The combination is universally jointed on its rear node and is oriented so that its axis always passes through the floating mark, by means of the taper guide rods.

The visual system is a complicated form of stereoscopic comparator, the object of which is to observe the stereoscopic coincidence of the floating marks with various objects in the landscape during plotting. It thus corresponds essentially to the anaglyph filters of a simple camera plastica. If the original negatives are placed in the projection cameras, a reconstructed space image as in nature is formed near the plane of the floating marks, since the auxiliary lens system introduces no inversion. Since this is viewed in reverse it is necessary to cross the eyepieces of the visual system in order to avoid pseudoscopy. (*See* BINOCULAR INSTRUMENTS; MICROSCOPE.) The eyepieces must for the sake of convenience remain immovable, while the floating marks travel on the direction plotting movement. This is effected by the introduction of scissor-jointed link prisms, which also serve to facilitate the crossing of the eyepieces. Lastly the line of collimation of the instrument must be universally jointed at the floating marks, in order that the movable part between the floating mark and the rear node of the auxiliary lens system may be deflected in a constant direction into the visual system. This is done by means of an optical Cardan link actuated by the taper guide rods. "Leaning" of the image introduced by rotation about the two Cardan axes is, as usual, corrected by the differential rotation of a Dove prism.

The Wild Autograph.—The latest complete example of stereophotogrammetric plotting machinery is the Wild "autograph," in which will be recognized the autocartograph and

stereoplanigraph characteristics. The projection cameras are rotatable about horizontal and vertical axes. They are connected to guide rods, which can slide in sleeves attached to universal joints at the ends of the base slide. The centres of these latter joints form a Zeiss parallelogram with the centres of rotation of the projection cameras; the base setting being effected entirely on the two former corners of the parallelogram.

All the three plotting movements act on the base slide B, and are geared to a drawing pencil in exactly the same way as in the stereoplanigraph. Sympathetic movements of the projection cameras follow by reason of their connection to the base slide through the guide rods. In addition the direction plotting movement is shared by two prisms of the visual system rigidly mounted on the vertical axis of the projection cameras Any tilts may be dealt with by an appropriate initial setting of these prisms or by tilting the whole visual system, and by an interchange of axes as in the stereoplanigraph.

Owing mainly to the absence of heavy moving parts the result is a light, compact machine. This very considerable advantage is however offset by further complication, since, in order to correct the effect of the above plotting movements, it is necessary to introduce a variable rotation of the plates in their own plane, *i.e.*, a rotation which must be varied for each particular tilt of the camera axes at exposure. This variable rotation, which is effected by a system of variable cams, is however entirely automatic, and requires no attention from the observer after the initial setting. There is little in it to go wrong or to require re-adjustment. A practical disadvantage of the machine for air work might lie in the necessity for computing the *relative* orientations of the camera axes in space before the machine can be set. In the case of ground surveys with the Wild phototheodolite, only a few combinations are necessary or possible, and the calculations can be done once and for all.

STEREOSCOPE. An optical instrument used for obtaining from two slightly different pictures (*i.e.*, pictures or photographs of the same object but from a slightly different point of view), the impression of a single picture in relief. *See* BINOCULAR INSTRUMENT.

STEREOSCOPIC VISION: *see* VISION

STEREOTYPING. A process of producing duplicate printing plates from a form of type or blocks by pouring molten metal on a matrix made in plaster of paris or papier-mâché (*See* PRINTING)

STERILITY, the inability to beget living offspring, may be the result of any of the following causes

Absence of sexual intercourse due to the lack of appropriate psychological stimuli leading to coition This is one factor in the mutual sterility of different species. (*See* HYBRIDISM)

Absence or incompleteness of coition due to gross abnormality of the external or internal organs of reproduction. Hermaphroditism (*see* article, SEX); occlusion of the ducts which convey the gametes from the sex-gland to the site of fertilisation, either congenital or acquired through disease; imperforate hymen and other structural abnormalities fall into this group The chemical condition of the female passages may be such as to kill the entering spermatozoa

Infecundity—The inability to produce functional gametes is found in many hybrids (*see* HYBRIDISM) and in certain intersexual forms. In such mammals in which the testes lie normally within a scrotum, the testis if retained within the abdominal cavity does not produce functional spermatozoa Infecundity may follow upon exposure to X-rays, for these destroy that tissue of the sex-gland which is concerned with the elaboration of the gametes.

Mutual repugnance on the part of the gametes resulting in non-fertilisation. Though as yet nothing very definite is known of the physico-chemical requirements of fertilisation there is a considerable body of evidence to show that an attraction between the male and female gametes must exist if fertilisation is to occur.

Abnormalities in the fertilised egg which embarrass or prevent cleavage and development bringing these processes to a stop at some stage, death of the individual thereupon resulting. This is the fate of many hybrid embryos. (*See* HYBRIDISM.) Lethal factors (*see* GENETICS and SEX) also operate in this fashion.

Abnormalities in the medium in which the fertilised eggs find themselves which prevent or embarrass development The exact constitution of the sea-water in terms of alkalinity, for example, determines whether or not the fertilised ova of marine organisms shall begin and continue their development. Pathological conditions within the uterus of the mammalian female can prevent proper implantation of the descending egg

Disharmonies between the developing offspring and the maternal environment can lead to difficult labour and death of either or of both mother and young For example the male cattle×bison hybrid has a prominent crest and this cannot be accommodated by the maternal passages of the cow. Such male hybrids therefore usually are still-born. Contracted pelvis and similar abnormalities of the female birth-canal are common causes of death of both infant and mother. The general well-being of the mother is necessary for the normal development of the infant she bears.

In the case of the human subject there are certain conditions which are essential to fertility. Healthy spermatozoa must be received into a healthy vagina with a normal cervix, uterus, tubes and ovaries. An examination of any case of sterility must therefore begin with an examination of the male. It is estimated that in 25 per cent of childless marriages the man is at fault.

Experimentation with laboratory animals has shown that infecundity may result from deficiency of the reproductive vitamin *E* (Mason, 1925).

STERLING, JOHN (1806–1844), British author, was born at Kames Castle in Bute on July 20, 1806. He belonged to a family of Scottish origin which had settled in Ireland during the Cromwellian period. He was the son of Edward Sterling (1773–1847), who was for many years a leader-writer on *The Times.* John Sterling was educated at Glasgow university and at Trinity college and Trinity Hall, Cambridge. At Cambridge he was a member of the famous "Apostles'" Club. With F. D. Maurice he purchased the *Athenaeum* in 1828 from J. Silk Buckingham, which was not a success. In 1834 he was ordained and became curate at Hurstmonceaux, where his old tutor Julius Hare was vicar. Acting on the advice of his physician he resigned his curacy in 1835, but, according to Carlyle, the primary cause was a divergence from the opinions of the Church He died at Ventnor on Sept. 18, 1844. Sterling owes his fame to the vivid *Life* by Carlyle, to whom, with Hare, his papers were entrusted.

STERLING, a term used to denote money of standard weight or quality, especially applied to the English gold sovereign, and hence with the general meaning of recognized worth or authority, genuine, of approved excellence The word has been generally derived from the name of "Easterlings" given to the North German merchants who came to England in the reign of Edward I. and formed a *hansa* or gild in London, modelled on the earlier one of the merchants of Cologne. Their coins were of uniform weight and excellence (*cf.* Matthew Paris, ann. 1247, *moneta esterlingorum, propter sui materiem desiderabilem*, etc., "money of the *esterlingi*, for its desirable materiel," etc.), and thus it is supposed gave the name of the moneyers to a coinage of recognized fineness This theory is based on the statement of Walter de Pinchbeck, a monk of the time of Edward I. (quoted in Wedgwood, *Dict. of Eng. Etym.*). The word, however, occurs much earlier. The *Roman de Rou* (1180) has "Pour ses estellins recevoir," and "in Anglia

unus Sterlingus per solvetur" occurs in an ordinance of Philip of France and Henry II. of England of 1184, both quoted in Du Cange (*Gloss., s.v.* Esterlingus). The "sterling" was a coin, the silver penny, 240 of which went to the "pound sterling" of silver of 5,760 grains, 925 fine, and described in a statute of Edward I., quoted in Du Cange, as "denarius Angliae qui vocatur sterlingus (the English penny, which is called Sterling)." The word was borrowed by most European languages and is there applied to English money.

STERLING, a city of Colorado, U.S.A., 140 m. N.E. of Denver, on the South Platte river and Federal highways 38 and 138, served by the Burlington Route and the Union Pacific railway systems; the county-seat of Logan county. The population was 6,415 in 1920 (87% native white) and was estimated locally at 9,000 in 1928. The city was founded in 1878 and incorporated in 1883. In 1900 the population was 998.

STERLING, a city of Whiteside county, Illinois, U.S.A., on the north bank of Rock river, 110 m. W. of Chicago. It is on the Lincoln highway and the Hennepin canal feeder, and is served by the Burlington Route and the Chicago and North-western railways, and by motor bus lines in all directions. Pop. 8,182 in 1920 (91% native white) and was estimated locally at over 10,000 in 1928. Rock Falls (pop. 2,927 in 1920) is just across the river. The cities have abundant water-power and large manufacturing industries, making agricultural implements. Sterling was chartered as a city in 1857.

STERN, DANIEL: *see* AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY.

STERNE, LAURENCE (1713–1768), English humorist, was the son of Roger Sterne, an English officer, and great-grandson of an archbishop of York. He was born at Clonmel, Ireland, on Nov. 24, 1713, a few days after the arrival of his father's regiment from Dunkirk. For ten years the boy and his mother moved from place to place after the regiment, from England to Ireland, and from one part of Ireland to another. Sterne's early knowledge of garrison life enabled him to draw the portraits of Uncle Toby and Corporal Trim. He was fixed for eight or nine years at a school at Halifax in Yorkshire. His father died when he was in his eighteenth year. He was sent to Jesus College, Cambridge, where he took his degree in 1736. Through the influence of his uncle, precentor and canon of York, he obtained (1738) the living of Sutton-in-the-Forest, near York. Two years after his marriage in 1741 to Elizabeth Lumley he was presented to the neighbouring living of Stillington, and did duty at both places. He was also a prebendary of York Cathedral.

Sutton was Sterne's residence for twenty uneventful years. He kept up an intimacy which had begun at Cambridge with John Hall-Stevenson (1718–1785), a witty and accomplished epicurean, owner of Skelton Hall ("Crazy Castle") in the Cleveland district of Yorkshire. Stevenson's various occasional sallies in verse and prose—his *Fables for Grown Gentlemen* (1761–1770), and his *Crazy Tales* (1762), bear a resemblance in spirit and turn of thought to Sterne's work, inferior as they are in literary genius. In 1759 Sterne wrote a skit on a quarrel between Dean Fountayne and Dr. Topham, a York lawyer, over the bestowal of an office in the gift of the archbishop. This sketch, in which Topham figures as Trim the sexton, and the author as Lorry Slim, gives an earnest of Sterne's powers as a humorist. It was not published until after his death, when it appeared in 1769 under the title of *A Political Romance,* and afterwards the *History of a Warm Watch-Coat*. The first two volumes of *Tristram Shandy* were issued at York in 1759 and advertised in London on Jan. 1, 1760, and at once made a sensation.

For the last eight years of his life after this sudden leap out of obscurity we have a faithful record of Sterne's feelings and movements in letters to various persons, published in 1775 by his only child, Lydia Sterne de Medalle, and in the *Letters from Yorick to Eliza* (1766–1767), also published in 1775. At the end of the sermon in *Tristram* he had intimated that, if this sample of Yorick's pulpit eloquence was liked, "there are now in the possession of the Shandy family as many as will make a handsome volume, at the world's service, and much good may they do it." Accordingly, when a second edition of the first instalment of *Tristram* was called for in three months, two volumes of *Sermons* by Yorick were announced. Although they had little or none of the eccentricity of the history, they proved almost as popular.

Sterne's clerical character was far from being universally injured by his indecorous freaks as a humorist: Lord Fauconberg presented the author of *Tristram Shandy* with the perpetual curacy of Coxwold. To this new residence he went in high spirits with his success, "fully determined to write as hard as could be," seeing no reason why he should not give the public two volumes of Shandyism every year and why this should not go on for forty years. Vols. iii. and iv. appeared in 1761; vols. v. and vi. in January 1762. But he was ordered to the south of France; and he came back after two and a half years very little stronger. He was overjoyed with his reception in Paris. He continued to build up his history of the Shandy family, but the work did not progress as rapidly as it had done. The digressions became extensive. In vol. vii. the work is allowed to stand still while the writer is being transported from Shandy Hall to Languedoc. Vol. viii. begins the long-promised story of Uncle Toby's amours with the Widow Wadman. After seeing to the publication of this instalment of *Tristram* and of another set of sermons—more pronouncedly Shandean in their eccentricity—he quitted England again in the summer of 1765, and travelled in Italy as far as Naples. The ninth and last and shortest volume of *Tristram*, concluding Toby Shandy's amours, appeared in 1767.

This despatched, Sterne turned to a new project, *The Sentimental Journey through France and Italy.* Its plan admitted of any length that the author chose, but, after seeing the first two volumes through the press in the early months of 1768, Sterne's strength failed, and he died in his lodgings, 41 Old Bond Street, London, March 18, three weeks after the publication.

An excellent edition of Sterne's works, edited by Professor George Saintsbury, was issued in six volumes in 1894. *See* also J. J. Texte, *Rousseau et les origines du cosmopolitisme littéraire* (1895); Thayer, *Laurence Sterne in Germany* (1905); W. L. Cross, *The Life and Times of Laurence Sterne* (2 vols. 1909, new ed. New Haven, 1925); Walter Sichel, *Sterne: a Study* (1910); L. Melville, *Life and Letters of Laurence Sterne* (2 vols. 1911); G. Rabizzani, *Sterne in Italia* (1920).

STESICHORUS (*c.* 640–555 B.C.), Greek lyric poet, a native of Himera in Sicily, or of Mataurus a Locrian colony in the south of Italy. The story of his being struck blind for slandering Helen and recovering his sight when he recanted is told by Plato among others. We possess about thirty fragments of his poems, none of them longer than six lines. They are written in the Doric dialect, with epic licences; the metre is dactylico-trochaic. Brief as they are, they show us what Longinus meant by calling Stesichorus "most like Homer"; they are full of epic grandeur, and have a stately sublimity that reminds us of Pindar. This use of lyric for heroic subjects is what Quintilian (*Instit.* x. 1, 62) means by saying that he "sustained the burden of epic poetry with the lyre." Several of his poems sung of the adventures of Heracles; one dealt with the siege of Thebes, another with the sack of Troy. The last is interesting as being the first poem containing that form of the story of Aeneas's flight to which Virgil afterwards gave currency in his *Aeneid.* The popular legends of Sicily also inspired his muse; he was the first to introduce the shepherd Daphnis who came to a miserable end after he had proved faithless to the nymph who loved him. Stesichorus completed the form of the ode by adding the epode to the strophe and antistrophe.

Fragments in T. Bergk, *Poetae lyrici graeci,* iii.

STETHOSCOPE, a medical instrument used in auscultation (*q.v.*). The single stethoscope is a straight wooden or metal tube with a small flattened bell, the surface of which is usually covered with ivory or bone at the end, which is placed against the body of the patient, and a large flat disc at the other end, for application to the ear of the observer. In the "binaural" stethoscope, which has the advantage of flexibility, the tube is divided above the bell into two flexible tubes which lead to both ears.

STETTIN, a seaport, capital of the Prussian province of Pomerania, on the Oder, 17 m. above its entrance into the Stettiner Haff, 30 m. from the Baltic, 84 m. N.E. of Berlin by rail, and at the junction of lines to Stargard-Danzig and Küstrin-

Breslau. Pop. (1925) 253,740. Stettin is said to have existed as a Wendish settlement in the 9th century, but its first authentic appearance in history was in the 12th century, when it was known as Stedyn. From the beginning of the 12th century to 1637 it was the residence of the dukes of Pomerania, one of whom gave it municipal rights in 1243. Already a leading centre of trade it entered the Hanseatic League in 1360. The Pomeranian dynasty became extinct in 1637, and in 1648 Stettin was ceded to Sweden. In 1678 it was taken from Sweden by Frederick William, elector of Brandenburg, but it was restored in 1679, only, however, to be ceded to Prussia in 1720 by the Peace of Stockholm It was fortified more strongly by Frederick the Great Stettin was the birthplace of the empress Catherine II. of Russia

The main part of the town occupies a hilly site on the left bank of the river, and is connected with the suburbs of Lastadie ("lading place" from *lastadium,* "burden,") and Silberwiese, on an island formed by the Parnitz and the Danzig. Until 1874 Stettin was closely girdled by extensive and strong fortifications. The church of St. Peter, founded in 1124 and restored in 1816–17, has the distinction of being the oldest Christian church in Pomerania Both this and the church of St. James, dating from the 14th century, are remarkable for their size. The old palace, now used as public offices, is a large but unattractive edifice. Two gateways, the Königstor and the Berliner Tor, remains of the old fortifications, are still standing.

Stettin, regarded as the port of Berlin, is one of the principal ship-building centres of Germany and a place of much commercial and industrial activity There are six floating docks, and four ice breakers keep the port open in winter A great impulse to its trade was given in 1898 by the opening of a free harbour adjoining the suburb of Lastadie on the east bank of the Oder; this embraces a total area of 137 acres. It has two basins, with the necessary accompaniment of cranes, storehouses, etc., and the Oder from Stettin to the Haff is 23 ft deep.

STEUBEN, BARON VON, FREDERICK WILLIAM AUGUSTUS HENRY FERDINAND (1730–1794), German soldier, born at Magdeburg, Prussia, Nov. 15, 1730, was a descendant of a noble family, which for generations had produced soldiers. From his 14th year, Steuben led a soldier's life. Reared in the rigorous military school of Frederick the Great, he took part in many battles of the Seven Years' War, where he so distinguished himself as to attract the attention of King Frederick, who appointed him as his aide-de-camp (1762). After the close of the Seven Years' War, he resigned from the army and became grand-marshal at the court of the Prince of Hohenzollern-Hechingen, and, after a service of ten years, accepted a similar position at the court of the margrave of Baden In 1777, his old friend the count of St. Germain, then the French minister of war, persuaded him to go to the assistance of the American colonists.

Steuben arrived at Portsmouth (N H), on Dec 1, 1777, and offered his services to Congress as a volunteer. In March 1778 he began drilling the inexperienced soldiers at Valley Forge; and by May he was made inspector-general or drill-master. He trained the soldiers admirably, adapting Prussian military ideas to the needs of his pupils Results of his work were shown in the next campaign, particularly at Monmouth, where he rallied the disordered, retreating troops of Gen. Charles Lee. His *Regulations for the Order and Discipline of the Troops of the United States* (1779) was of great value to the army. He was a member of the court-martial which tried Maj. John André in 1780, and after Gen Horatio Gates's defeat at Camden was placed in command of the district of Virginia, with instructions "to collect, organize, discipline and expedite the recruits for the Southern Army."

In April 1781 he was superseded in command of Virginia by La Fayette, and later took part in the siege of Yorktown Retiring from the service after the war, he passed the last years of his life at Steubenville (N Y), where he died on Nov. 28, 1794. New York, Virginia, Pennsylvania and New Jersey gave him grants of land for his services, and Congress passed a vote of thanks and gave him a gold-hilted sword in 1784, and later granted him a pension of $2,400

See Frederick Kapp, *The Life of Frederick William von Steuben* (1859); and George W. Greene, *The German Element in the War of American Independence* (Cambridge, Mass., 1876); Francis Bowen, "Life of Baron Steuben" in J. Sparks's *Library of American Biography,* vol. viii, pp. 119–202 (1902); Rudolf Cronan, "The Army of the American Revolution and its Organizer," *American Historical Review* vol. xxxi. pp. 455–458 (1923).

STEUBENVILLE, a city of eastern Ohio, U.S.A., on the Ohio river, 40 m. W. of Pittsburgh; the county seat of Jefferson county. It is served by the Pennsylvania, the Wheeling and Lake Erie, and electric railways, motor-bus and truck lines, and river packets and barges. Two highway bridges span the Ohio. Pop (1920), 28,508 (20% foreign-born white); 1928 local estimate 37,500 The city lies on a plain 700 ft. above sea-level, surrounded by hills rising 300–500 ft. higher, in a beautiful and fertile region containing rich deposits of coal, oil, gas, clay and building-stone The coal-mines of the county had an output of 5,154,753 tons in 1926 There are two power plants generating 600,000 h p of electrical energy at the mines. The manufacturing industries are large and varied, including iron, steel, paper, glass and clay works, and the aggregate output in 1927 was valued at $61,500,000 Bank clearings in 1927 amounted to $135,845,732. Steubenville was planned in 1797, immediately after the erection of the county, on the site of Ft. Steuben (built 1786 and named after Baron von Steuben). It was chartered as a city in 1851.

STEVENAGE, an urban district of Hertfordshire, England, 28½ m. N of London by the L N E. railway Pop (1921) 5,038. The church of St. Nicholas, with a graceful tower and spire, is mainly Early English, but has Norman and later portions. There is a grammar school, founded in 1558.

STEVENS, ALFRED (1818–1875), British sculptor, was born at Blandford in Dorset on Jan 28, 1818. He was the son of a house painter In 1833 the rector of his parish sent him to Italy, where he spent nine years in study at Naples, Rome, Florence, Milan and Venice He had never been at an English school In 1841 Thorwaldsen employed him for a year in Rome After this he left Italy for England, and in 1845 he obtained a tutorial position in the School of Design, London, which he held until 1847. In 1850 he became chief artist to a Sheffield firm of workers in bronze and metal In 1852 he returned to London To this period belongs his design for the vases on the railings in front of the British Museum, and also the lions on the dwarf posts which were subsequently transferred to the inside of the museum In 1856 Stevens agreed to execute the Wellington monument for St Paul's Cathedral for the sum of £20,000

Stevens died in London on May 1, 1875.

See SCULPTURE: *British;* Sir William Armstrong, *Alfred Stevens* (1881); H. Stannus, *Alfred Stevens* (1891).

STEVENS, ALFRED (1828–1906), Belgian painter, was born in Brussels on May 11, 1828. His father, an officer in the service of William I, king of the Netherlands, encouraged his son's talent and sent him to draw in the studio of François Navez, director of the Brussels Academy. In 1844 Stevens went to Paris and worked under Camille Roqueplan, a friend of his father's, he also attended the classes at the École des Beaux Arts, where Ingres was then professor. In 1849 he settled in Paris, where he exhibited in the Salons. In 1855 he exhibited at the Antwerp Salon a little picture called "At Home," which showed his genius for depicting ladies of fashion. Henceforth he concentrated on graceful female subjects At the Historical Exhibition of Belgian Art, Brussels, 1880, he exhibited "The Four Seasons" (in the Palace at Brussels), "The Parisian Sphinx," "The Japanese Mask," "The Japanese Robe," and "The Lady-bird" (Brussels Gallery) He died on Aug. 24, 1906.

STEVENS, HENRY (1819–1886), American bibliographer, was born in Barnet, Vt., on Aug. 24, 1819. He studied at Middlebury college, Vermont, and graduated at Yale in 1843, teaching to pay his way and for a time acting as a Government clerk. In this capacity he won the friendship of Col Peter Force, who employed him to collect books, pamphlets and manuscripts for the American archives on his return to Yale, and during his year

at the Cambridge, Mass., law school. His commissions from Force and other collectors took him abroad, where he ransacked the European capitals for rare Americana for the Smithsonian Institution, the library of Congress, and such private buyers as John Carter Brown and James Lenox. At the suggestion of Sir Anthony Panizzi, the librarian of the British Museum, he also supplied that institution with many American books. He died at Hampstead, London, England, on Feb. 28, 1886.

Perhaps his most notable achievement was his redemption of the Franklin manuscripts, which were finally disposed of to the U.S. Government. He wrote: *Catalogue of the American Books in the Library of the British Museum* (1856); *Historical Nuggets, Bibliotheca Americana* (1862); *Historical and Geographical Notes on the Earliest Discoveries in America* (1869); *Benjamin Franklin's Life and Writings* (1881); *Recollections of Mr. James Lenox . . . and the Formation of His Library* (1886); and *Thomas Hariot* (1900); edited by his son, H. N. Stevens.

STEVENS, JOHN (1749–1838), American inventor, was born in New York City in 1749, graduated at Columbia university in 1768, subsequently studied law and was admitted to the New York bar in 1771. In 1776 he became a captain in the Revolutionary army, and later colonel of his own regiment. From 1777 to 1782 he served as treasurer of the State of New Jersey. In 1784 he built a home on what was then the Island of Hoboken, subsequently, when connected with the mainland, known as Stevens Point, where he resided for over half a century until his death March 6, 1838. He purchased the ferry to New York and much of the main New Jersey shore. Along the road leading to the ferry landing he began the development of the city of Hoboken.

The problem of safe and speedy transportation across the Hudson drew his interest early to the possibilities of steam navigation. In 1788 he built the first multitubular boiler on record for use in his marine engines. In a desire to protect this invention he petitioned Congress for a patent law, which he outlined, and which was passed as the Patent Law of 1790 the foundation of the present patent system. He was the first to apply the principle of screw propulsion to navigation, building in 1802 a steamboat with two underwater propellers of screw type in the stern which successfully crossed the Hudson several times and only failed because the inefficient boilers of that day could not generate enough power to make the screw device practical. He turned then toward the development of high pressure steam engines and boilers in which field he was a pioneer. But a few days after Fulton's successful trial of the "Clermont" Stevens launched the "Phoenix," the engine of which was built by Stevens himself, whereas that of the "Clermont" was imported from England. Fulton having received a monopoly grant of navigation rights on the Hudson, Stevens sent the "Phoenix" by sea to Philadelphia, the first voyage of a steamship on ocean waters. Stevens was also interested in railways, writing in 1812 a pamphlet entitled *Documents tending to prove the Superior Advantages of Railways and Steam Carriages over Canal Navigation.* On February 6, 1815, he obtained the first railway charter granted in America for a railway between the Delaware and Raritan rivers, but it was not until 1830 that he formed the Camden and Amboy Railway company, and 1832 that he completed the first railway across New Jersey, operated by his sons Robert L. Stevens (*q.v.*) and Edward A. Stevens.

See A. D. Turnbull, *John Stevens: An American Record* (1928).

STEVENS, ROBERT LIVINGSTON (1787–1856), American mechanical engineer, was born at New York City on Oct. 18, 1787, the son of John Stevens (*q.v.*) whose mechanical ability he inherited. Whereas the father spent most of his thought on the improvement of motive-power and machinery of steamboats, the son made many advances in construction, strengthening hulls, reducing weight, distributing strain and improving the lines to gain speed. He designed the false bow, which, when first introduced on the "New Philadelphia," enabled that steamer to break previous records and be the first of Hudson river steamers to go from Albany to New York during daylight. With this steamer and the "North America," the Stevens family inaugurated a day line on the Hudson. In 1822 he built the ferryboat "Hoboken" on modern lines and introduced the piled slip which directed the boat's entrance to the landing-place.

In 1830 he was made first president of the Camden and Amboy railway and went to England to inspect equipment already in use there. On the outward voyage he designed the "T" rail with a broad base, long known as the Stevens, or American rail, and now universally used. He contracted in England for 500 tons of such rails, the first made, and also placed an order with the Stephensons for a locomotive made according to his specifications. This was the famous "John Bull" which he brought to America on his return, and which is now in the Smithsonian Institution. He made many improvements on railway locomotives, introducing the pilot truck in 1832, the bogie truck shortly afterwards, and, finally, using eight instead of four or six wheels in order to promote adhesion to the rails and drawing power. When stone blocks could not be furnished fast enough for his road-bed he resorted to logs laid crosswise with broken stone and gravel between and discovered that he had found a bed more serviceable and comfortable than any known previously. He devised spikes "six inches long with heads" to hold the rails in place on the logs. As a recreation Stevens took up yachting, and in 1844 he designed the "Maria," for twenty years the swiftest yacht afloat. Later he designed the "America" for his brother, John Cox Stevens, who with it defeated all English challengers, and founded the America's Cup races. He died at Hoboken, New Jersey, April 20, 1856.

STEVENS, THADDEUS (1792–1868), American political leader, was born in Danville, Vt., on April 4, 1792. He graduated at Dartmouth college in 1814, removed to York, Pa., was admitted to the bar (in Maryland), and for 15 years practised at Gettysburg, Pa. He frequently appeared in behalf of fugitive slaves before the Pennsylvania courts. In 1840 he did much to bring about the election of W. H. Harrison, and in the campaign of 1844 Stevens again rendered marked services to the Whig ticket. He was a Whig representative in Congress in 1849–53, and was leader of the radical Whigs and Free-Soilers, strongly opposing the Compromise Measures of 1850, and being especially bitter in his denunciations of the Fugitive Slave law. In 1855 he took a prominent part in organizing the Republican party in Pennsylvania, and in 1856 was a delegate to the Republican national convention. He became chairman of the ways and means committee on July 4, 1861, and until his death was, as James G. Blaine said, "the natural leader who assumed his place by common consent." During the Civil War he was instrumental in having necessary revenue measures passed in behalf of the administration. He was not, however, in perfect harmony with Lincoln, who was far more conservative than Stevens. He introduced from the joint committee what became the Fourteenth Amendment, and also the Reconstruction Act of Feb. 6, 1867. He also advocated the Freedmen's Bureau bills and the Tenure of Office Act, and went beyond Congress in favouring the confiscation of the property of the Confederate States. He led Congress in the struggle with the President, and after the President's removal of Secretary of War Stanton he reported the impeachment resolution to the house and was chairman of the committee appointed to draft the articles of impeachment. He died at Washington, D.C., on Aug. 11, 1868, and was buried at Lancaster, Pa.

Rhodes, *History of the United States from the Compromise of 1850* (1904); W. U. Hensel, "Thaddeus Stevens as a Country Lawyer," *Green Bag*, vol. xviii. p. 641–656 (1906); James Albert Woodburn, "The Attitude of Thaddeus Stevens Toward the Conduct of the War," *American History Review*, vol. xii. p. 567–583 (1907); and James Albert Woodburn, *The Life of Thaddeus Stevens.*

STEVENSON, ROBERT (1772–1850), Scottish engineer, was the only son of Alan Stevenson, partner in a West Indian house in Glasgow, and was born in that city on June 8, 1772. He was educated at Anderson's College, Glasgow, and at Edinburgh University. He assisted his stepfather, Thomas Smith, in lighthouse schemes, and at nineteen was sent to superintend the erection of a lighthouse on the island of Little Cumbrae. Subsequently he succeeded Smith as engineer to the Commissioners of Northern Lighthouses, and from 1797 to 1843, he designed and built a large number of lighthouses, the most important being that on the Bell

Rock, begun in 1807. On his advice an admiralty survey was established, from which the admiralty sailing directions for the coasts of Great Britain and Ireland were prepared. Stevenson published an *Account of the Bell Rock Lighthouse* in 1824, contributed to the *Encyclopædia Britannica,* and wrote various papers read before learned societies. He died at Edinburgh on July 12, 1850.

STEVENSON, ROBERT LOUIS BALFOUR (1850–1894), British essayist, novelist and poet, was the only child of Thomas Stevenson, civil engineer, and his wife, Margaret Isabella Balfour. He was born at 8 Howard Place, Edinburgh, on Nov 13, 1850. He suffered from infancy from great fragility of health, and nearly died in 1858 of gastric fever, which left much constitutional weakness behind it. He went to school, mainly in Edinburgh, from 1858 to 1867. As his health improved it was hoped that he would be able to adopt the family profession of civil engineering, and in 1868 he went to Anstruther and then to Wick as a pupil engineer In 1871 he had so far advanced as to receive the silver medal of the Edinburgh Society of Arts for a paper suggesting improvements in lighthouse apparatus. His earliest publication, the anonymous pamphlet of *The Pentland Rising,* had appeared in 1866, and *The Charity Bazaar,* a trifle in which his future manner is happily displayed, in 1868. Though he greatly enjoyed the outdoor business of the engineer's life it strained his physical endurance too much, and in 1871 it was reluctantly exchanged for study at the Edinburgh bar, to which he was called in 1875. In 1873 he first met Sidney Colvin, who was to prove the closest of his friends and at last the loyal and admirable editor of his works and his correspondence.

He was now labouring, with extreme assiduity, to ground himself in the forms and habits of literary style. In 1875 appeared, anonymously, his *Appeal to the Clergy of the Church of Scotland,* and in that year he made the first of many visits to the forest of Fontainebleau Meanwhile at Mentone in the winter of 1873–1874 he had grown in mind under the shadow of extreme physical weakness, and in the following spring began to contribute essays of high originality to one or two periodicals, of which the *Cornhill,* then edited by Leslie Stephen, was at first the most important. Stevenson made no attempt to practise at the bar, and the next years were spent in wanderings in France, Germany and Scotland Records of these journeys were published as *An Inland Voyage* (1878), and as *Travels with a Donkey in the Cevennes* (1879). During these four years Stevenson's health, which was always bettered by life out of doors, gave him little trouble. At Fontainebleau in 1876 Stevenson had met Mrs Osbourne, the lady who afterwards became his wife; she returned to her home in California in 1878, and in August of the following year, alarmed at news of her illness, Stevenson hurriedly crossed the Atlantic. He travelled, from lack of means, as a steerage passenger and then as an emigrant, and in December, after hardships which seriously affected his health, he arrived in San Francisco In May 1880 he married, and moved to the desolate mining-camp which he has described in *The Silverado Squatters* Some of his most poignant and most enchanting letters were written during this romantic period of his life. In the autumn of 1880 he returned to Scotland, with his wife and stepson, who were received at once into the Edinburgh household of his parents. But the condition of his health continued to be very alarming, and they went almost immediately to Davos, where he remained until the spring of 1881. In this year was published *Virginibus puerisque,* the earliest collection of Stevenson's essays. He spent the summer months in Scotland, writing articles, poems, and above all his first romance, *The Sea-Cook,* afterwards known as *Treasure Island;* but he was driven back to Davos in October. In 1882 appeared *Familiar Studies of Men and Books* and *New Arabian Nights.* His two winters at Davos had done him some good, but his summers in Scotland invariably undid the benefit. He therefore determined to reside wholly in the south of Europe, and in the autumn of 1882 he settled near Marseilles. This did not suit him, but from March 1883 to July 1884 he was at home at a charming house called La Solitude, above Hyères; this was in many ways to be the happiest station in the painful and hurrying pilgrimage of Stevenson's life. *The Silverado Squatters* was published in 1883, and also the more important *Treasure Island,* which made Stevenson for the first time a popular writer. He planned a vast amount of work, but his schemes were all frustrated in January 1884 by the most serious illness from which he had yet suffered. The attack was followed by long prostration and incapacity for work, and by continued relapses. In July he was brought back to England, and from this time until August 1887 Stevenson's home was at Bournemouth. In 1885 he published, after long indecision, his volume of poems, *A Child's Garden of Verses,* an inferior story, *The Body Snatcher,* and that admirable romance, *Prince Otto,* in which the peculiar quality of Stevenson's style was displayed at its highest. He also collaborated with W. E. Henley in some plays, *Beau Austin, Admiral Guinea* and *Robert Macaire.* Early in 1886 he struck the public taste with precision in his wild symbolic tale of *The Strange Case of Dr. Jekyll and Mr. Hyde.* In the summer of the same year he published *Kidnapped,* which had been written at Bournemouth.

Stevenson printed privately as a pamphlet, in June 1887, a brief and touching sketch of his father. In July he published his volume of lyrical poems called *Underwoods.* The ties which bound him to England were now severed, and he determined to remove to another hemisphere He sailed from London, with his wife, mother and stepson, for New York on Aug. 17, 1887. He never set foot in Europe again His memoir of his friend Professor Fleeming Jenkin was published soon after his departure. After resting at Newport, he went for the winter to be under the care of a physician at Saranac Lake in the Adirondacks. In this retreat he was very quiet, and steadily active with his pen, writing both the greater part of the *Master of Ballantrae* and many of his finest later essays. He had undertaken to contribute a monthly essay to *Scribner's Magazine,* and these essays, twelve in number, were published continuously throughout the year 1888. Early in that year was begun *The Wrong Box,* a farcical romance in which Mr. Lloyd Osbourne participated; Stevenson also began a romance about the Indian Mutiny, which he abandoned. His attitude about this time to life and experience is reflected in *Pulvis et umbra,* one of the noblest of all his essays In April 1888 he was at the coast of New Jersey for some weeks, and in June started for San Francisco, where he had ordered a schooner, the "Casco," to be ready to receive him. On the 28th of the month, he started, as Mr. Colvin has said, "on what was only intended to be a pleasure excursion . . . but turned into a voluntary exile prolonged until the hour of his death": he never again left the waters of the Pacific. The "Casco" proceeded first to the Marquesas, and south and east to Tahiti, passing before Christmas northwards to Honolulu, where Stevenson spent six months and finished *The Master of Ballantrae* and *The Wrong Box.* It was during this time that he paid his famous visit to the leper settlement at Molokai In 1889, "on a certain bright June day," the Stevensons sailed for the Gilbert Islands, and after six months' cruising found themselves at Samoa, where he landed for the first time about Christmas Day 1889. On this occasion, however, though strongly drawn to the beautiful island, he stayed not longer than six weeks, and proceeded to Sydney, where early in 1890, he published, in a blaze of righteous anger, his *Father Damien: an Open Letter to the Rev. Dr. Hyde of Honolulu,* in vindication of the memory of Father Damien and his work among the lepers of the Pacific. Meanwhile his volume of *Ballads* was published in London.

The last four years of his unquiet life were spent at Samoa, in circumstances of such health and vigour as he had never previously enjoyed, and in surroundings singularly picturesque. In November 1890 he made his abode at Vailima, where he took a small barrack of a wooden box 500 ft. above the sea, and began to build himself a large house close by. The natives gave him the name of Tusitala. He took up the cause of the deposed king Mataafa with extreme ardour, and he wrote a book, *A Footnote to History: Eight Years of Trouble in Samoa* (1892), in the endeavour to win over British sympathy to his native friends. In the autumn of this year he received a visit at Vailima from the countess of Jersey, in company with whom and some others

he wrote the burlesque extravaganza in prose and verse, called *An Object of Pity,* privately printed in 1893 at Sydney. Whenever the cultivation of his estate and the vigorous championship of his Samoan retainers gave him the leisure, Stevenson was during these years almost wholly occupied in writing romances of Scottish life. *The Wrecker,* an adventurous tale of American life, which mainly belonged to an earlier time, was written in collaboration with Mr. Lloyd Osbourne and finally published in 1892; and towards the close of that very eventful and busy year he began *The Justice Clerk,* afterwards *Weir of Hermiston.* In 1893 Stevenson published the Scottish romance of *Catriona,* written as a sequel to *Kidnapped,* and the three tales illustrative of Pacific Ocean character, *Island Nights' Entertainments.* But in 1893 the uniform good fortune which had attended the Stevensons since their settlement in Samoa began to be disturbed. The whole family at Vailima became ill, and the final subjugation of his protégé Mataafa, and the destruction of his party in Samoan politics, deeply distressed and discouraged Stevenson. In a series of letters to *The Times* he exposed the policy of the chief justice, Mr. Cedercrantz, and the president of the council, Baron Senfft. He so influenced public opinion that both were removed from office. In the autumn of that year he went for a change of scene to the Sandwich Islands, but was taken ill there, and was only too glad to return to Samoa. In 1894 he was greatly cheered by the plan, suggested by friends in England and carried out by them with the greatest energy, of the noble collection of his works in twenty-eight volumes, since known as the Edinburgh edition. In September 1894 was published *The Ebb Tide,* the latest of his books which he saw through the press. Of Stevenson's daily avocations, and of the temper of his mind through these years of romantic exile, a clear idea may be obtained by the posthumous *Vailima Letters,* edited by Mr. Sidney Colvin in 1895. Through 1894 he was engaged in composing two romances, neither of which he lived to complete. He was dictating *Weir of Hermiston,* apparently in his usual health, on the day he died. This was Dec. 3, 1894; he was gaily talking on the verandah of his house at Vailima when he had a stroke of apoplexy, from which he never recovered consciousness, and passed away painlessly in the course of the evening. His body was carried next day by sixty sturdy Samoans, who acknowledged Stevenson as their chief, to the summit of the precipitous peak of Vaea, where he had wished to be buried, with the Pacific Ocean at his feet.

The charm of the personal character of Stevenson and the romantic vicissitudes of his life are so predominant in the minds of all who knew him, or lived within earshot of his legend, that they made the ultimate position which he will take in the history of English literature somewhat difficult to decide. That he was the most attractive figure of a man of letters in his generation is admitted; and the acknowledged fascination of his character was deepened, and was extended over an extremely wide circle of readers, by the publication in 1899 of his *Letters,* which have subdued even those who were rebellious to the entertainment of his books. It is therefore from the point of view of its "charm" that the genius of Stevenson must be approached, and in this respect there was between himself and his books, his manners and his style, his practice and his theory, a very unusual harmony.

The personal appearance of Stevenson has often been described: he was tall, extremely thin, dark-haired, restless, compelling attention with the lustre of his wonderful brown eyes. Whatever may be the ultimate order of reputation among his various books, or whatever posterity may ultimately see fit to ordain as regards the popularity of any of them, it is difficult to believe that the time will ever come in which Stevenson will not be remembered as the most beloved of the writers of that age which he did so much to cheer and stimulate. (E. G.; X.)

R. L. Stevenson's other works include: *Memories and Portraits* (1887); *The Merry Men and other Tales and Fables* (1887); *The Black Arrow* (1888); *Edinburgh: Picturesque Notes* (1889); *Across the Plains, with other Memories and Essays* (1892), and the posthumous works, *Songs of Travel and other Verses* (1896), *St. Ives* (1899), completed by Sir A. T. Quiller Couch; *A Stevenson Medley* (1899); *In the South Seas: experiences . . . on the "Casco" (1888) and the Equator (1889)* (1900). *See* the *Letters of Stevenson to his Family* (1899), with the critical and biographical preface by Mr. Sidney Colvin; *Vailima Letters, to Sidney Colvin* (1895), and the *Life of Robert Louis Stevenson* by Graham Balfour (1901) A complete edition of Stevenson's works was issued at Edinburgh in 1894–98. *Bibliographies* of the works of R. L. Stevenson were published by J. H. Slater (1914) and by W. F. Prideaux (1917).

See Prof. Walter Raleigh, *R. L. Stevenson* (1895); Isobel Strong and Lloyd Osbourne, *Memories of Vailima* (1903); F. A. Swinnerton, *R. L. Stevenson: a critical study* (1914); G. Balfour, *The Life of Robert Louis Stevenson* (1918 rev. ed. 1922); G. E. Brown, *A Book of R. L. S. Works, travels, friends and commentators* (1919); R. O. Masson, *Life of R. L. Stevenson* (Edinburgh, 1923); A. St. John Adcock, *Robert Louis Stevenson: his work and his personality* (1924); J. A. Stewart, *R. L. Stevenson, Man and Writer* (2 vols., 1924); G. S. Hellman, *The True Stevenson: A study in clarification* (1925).

STEVENSON, WILLIAM (d. 1575), probable author of the English comedy *Gammer Gurton's Needle,* was born at Hunwick, Durham, matriculated in 1546, took his M. A. degree in 1553, and became B.D. in 1560. Stevenson was a fellow of Christ's college, Cambridge, from 1551 to 1554 and from 1559 to 1561. He was made a prebendary of Durham in 1560–61 and died in 1575. *Gammer Gurton's Needle* is the second extant English comedy, properly so-called. William Stevenson is known to have written a play which was acted at Christ's college in 1553–54; and in the accounts of Christ's college for 1559–60 is the entry, "Spent at Mr. Stevenson's plaie, 5s." Contemporary Puritan writers in the Marprelate tracts allude to Dr. John Bridges, dean of Salisbury, author of *A Defence of the Government of the Church of England,* as the reputed author of *Gammer Gurton's Needle,* but he obviously could not be properly described as "Mr. S." He took his M.A. degree at Pembroke college, Cambridge, in 1560. He may possibly have been a coadjutor.

See Henry Bradley's essay prefixed to his edition of the play in *Representative English Comedies* (1903). The piece is also reprinted in Dodsley's *Old Plays* (vol. 1., 1744; vol. 2., 1780); in *Ancient British Drama* (1810), vol. 1.; and in J. M. Manley's *Specimens of the Pre-Shakespearean Drama* (Boston, U.S.A., 1897). *See* also H. F. B. Brett-Smith's edition of *Gammer Gurton's Needle* (Percy Reprints, 1920).

STEVENS POINT, a city of central Wisconsin, U.S.A., on the Wisconsin river; the county seat of Portage county. It is on Federal highways 10 and 51, and is served by the Green Bay and Western and the Soo Line railways. Pop. (1920) 11,371 (86% native white). The village was incorporated in 1847 and was chartered as a city in 1858.

STEVENSTON, manufacturing town and parish of Ayrshire, Scotland. Pop. (1921) 8,575. It is situated about 1 m. from Saltcoats on the coast of the Firth of Clyde, 29 m. S.W. of Glasgow by the L.M.S. railway. There are coal-mines, large ironworks and foundries, and, on the sandhills along the shore, the works of Nobel's Explosives company.

STEVINUS, SIMON (1548–1620), Dutch mathematician, was born in 1548 at Bruges and died in 1620 at The Hague or in Leyden. He was director of the "waterstaet," and afterwards quartermaster-general. Stevinus was known to his contemporaries by his military methods and inventions; he invented defence by a system of sluices which was of great importance in the Netherlands. He also invented a carriage with sails which was used on the seashore and carried 26 passengers.

In his *Statics and Hydrostatics* (Leyden, 1586) he enunciated the important theorem of the triangle of forces. This gave a new impetus to the study of statics, which had previously been founded on the theory of the lever. He discovered the hydrostatic paradox that the downward pressure of a liquid is independent of the shape of the vessel, and depends only on its height and base.

In 1586 he published a pamphlet of a few pages, the French translation of which is entitled *La Disme enseignant facilement expédier par Nombres Entiers sans rompuz tous Comptes se rencontrans aux Affaires des Hommes.* In this he treated decimal fractions. Decimal fractions and fractions had been employed for the extraction of square roots some five centuries before his time, but nobody before Stevinus established their daily use. He declared the universal introduction of decimal coinage, measures and weights to be only a question of time. His notation is rather unwieldy. He printed little circles round the exponents of the different powers of one-tenth. For instance, $237\frac{578}{1000}$ was printed

237 ⓪ 5 ① 7 ② 8 ③; and the fact that Stevinus meant those encircled numerals to denote mere exponents is evident from his employing the same sign for powers of algebraic quantities, *e.g.*, 9 ④ − 14 ③ + 6 ① − 5 to denote $9x^4-14x^3+6x-5$.

A number of his writings were translated into Latin by W. Snellius. There are two complete editions in French of his works (Leyden, 1608 and 1634) by Albert Girard *See* Steichen, *Vie et travaux de Simon Stevin* (Brussels, 1846); M. Cantor, *Geschichte der Mathematik.*

STEWART, STUART or **STEUART,** the surname of a family which inherited the Scottish and ultimately the English crown. Their descent is traced to a Breton immigrant, Alan the son of Flaald, which Flaald was a brother of Alan, steward (or seneschal) of Dol in Brittany. This elder Alan, whose name occurs in Breton documents before 1080, went on crusade in 1097, and was apparently succeeded by his brother Flaald, whose son, the younger Alan, enjoyed the favour of Henry I, who bestowed on him Mileham and its barony in Norfolk, where he founded Sporle Priory. By the daughter of Ernulf de Hesdin (in Picardy), a Domesday baron, he was father of at least three sons: Jordan, who succeeded to the family office of steward of Dol; William, who inherited Mileham and other estates in England, and who founded the great baronial house of Fitz Alan (afterwards earls of Arundel); and Walter, who was made by David I. steward (*dapifer*) or seneschal of Scotland The Scottish king conferred on Walter various lands in Renfrewshire, including Paisley, where he founded the abbey in 1163. Walter, his grandson, third steward, was appointed by Alexander II. justiciary of Scotland, and, dying in 1246, left four sons and three daughters. The third son, Walter, obtained by marriage the earldom of Menteith, which ultimately came by marriage to Robert, duke of Albany, son of Robert II. Alexander, fourth steward, the eldest son of Walter, third steward, inherited by his marriage with Jean, granddaughter of Somerled, the islands of Bute and Arran, and on Oct. 2, 1263 led the Scots against Haakon IV, king of Norway, at Largs. He had two sons, James and John. The latter, who commanded the men of Bute at the battle of Falkirk in 1298, had seven sons: (1) Sir Alexander, whose grandson George became in 1389 earl of Angus, the title afterwards passing in the female line to the Douglases, and in 1761 to the duke of Hamilton; (2) Sir Alan of Dreghorn, ancestor of the earls and dukes of Lennox, from whom Lord Darnley, husband of Queen Mary, and also Lady Arabella Stuart, were descended; (3) Sir Walter, who obtained the barony of Garlies, Wigtownshire, from his uncle John Randolph, earl of Moray, and was the ancestor of the earls of Galloway, younger branches of the family being the Stewarts of Tonderghie, Wigtownshire, and also those of Physgill and Glenturk in the same county; (4) Sir James, who fell at Dupplin in 1332, ancestor of the lords of Lorn, on whose descendants were conferred at different periods the earldoms of Athole, Buchan and Traquair, and who were also the progenitors of the Stewarts of Appin, Argyllshire, and of Grandtully, Perthshire; (5) Sir John, killed at Halidon Hill in 1333; (6) Sir Hugh, who fought under Edward Bruce in Ireland; and (7) Sir Robert of Daldowie, ancestor of the Stewarts of Allanton and of Coltness. James Stewart, the elder son of Alexander, fourth steward, succeeded his father in 1283, and, after distinguishing himself in the wars of Wallace and of Bruce, died in 1309. His son Walter, sixth steward, who had joint command with Sir James Douglas of the left wing at the battle of Bannockburn, married Marjory, daughter of Robert the Bruce, and during the latter's absence in Ireland was entrusted with the government of the kingdom. He died in 1326, leaving an only son, who as Robert II. ascended the throne of Scotland in 1371 Sir Alexander Stewart, earl of Buchan, fourth son of Robert II., who earned by his ferocity the title of the "Wolf of Badenoch," inherited by his wife the earldom of Ross, but died without legitimate issue, although from his illegitimate offspring were descended the Stewarts of Belladrum, of Athole, of Garth, of Urrard and of St. Fort. On the death of the "Wolf of Badenoch" the earldom of Buchan passed to his brother Robert, duke of Albany, also earl of Fife and earl of Menteith, but these earldoms were forfeited on the execution of his son Murdoch in 1425, the earldom of Buchan again, however, coming to the house of Stewart in the person of James, second son of Sir James Stewart, the black knight of Lorn, by Joan or Joanna, widow of King James I. From Murdoch, duke of Albany, were descended the Stewarts of Ardvoirlich and other families of the name in Perthshire, and also the Stuarts of Inchbreck and Laithers, Aberdeenshire. From a natural son of Robert II. were descended the Steuarts of Dalguise, Perthshire, and from a natural son of Robert III. the Shaw Stewarts of Blackhall and Greenock. The direct male line of the royal family terminated with the death of James V. in 1542, whose daughter Mary was the first to adopt the spelling "Stuart." Mary was succeeded in her lifetime in 1567 by her only son James VI., who through his father Lord Darnley was also head of the second branch, there being no surviving male issue of the family from progenitors later than Robert II. In James V., son of James IV. by Margaret, daughter of Henry VII., the claims of Margaret's descendants became merged in the Scottish line, and on the death of Queen Elizabeth of England, the last surviving descendant of Henry VIII., James VI. of Scotland, lineally the nearest heir, was proclaimed king of England, in accordance with the arrangements made by Lord Burghley and Elizabeth's other advisers. The accession of James was, however, contrary to the will of Henry VIII., which favoured the heirs of his younger sister Mary, wife of Charles Brandon, duke of Suffolk.

By the usurpation of Cromwell the Stuarts were excluded from the throne from the defeat of Charles I. at Naseby in 1645 until the restoration of his son Charles II. on May 8, 1660. On the death of Charles II. without issue in 1685, his brother James, duke of York, ascended the throne as James II, but he so alienated the sympathies of the nation by his unconstitutional efforts to further the Roman Catholic religion that an invitation was sent to the prince of Orange to come "to the rescue of the laws and religion of England." Next to the son of James II., still an infant under his father's control, Mary, princess of Orange, elder daughter of James II., had the strongest claim to the crown; but the claims of the prince of Orange also, even apart from his marriage, were not very remote, since he was the son of Mary, eldest daughter of Charles I. The marriage had strengthened the claims of both, and they were proclaimed joint sovereigns of England on Feb. 12, 1689, Scotland following the example of England on April 11. They left no issue, and the Act of Settlement, passed in 1701, excluding Roman Catholics from the throne, secured the succession to Anne, second daughter of James II, and on her death without issue (1714) to the Protestant house of Hanover, descended from the princess Elizabeth, daughter of James I, wife of Frederick V, count palatine of the Rhine George, elector of Hanover, eldest son of Sophia (youngest child of the princess Elizabeth), and Ernest, elector of Brunswick-Lüneburg, or Hanover, became sovereign of Great Britain and Ireland. The female issue of James II. ended with the death of Anne. James, called James III. by the Jacobites and the Old Pretender by the Hanoverians, had two sons—Charles Edward, the Young Pretender, who died without legitimate issue in 1780, and Henry Stuart, titular duke of York, commonly called Cardinal York, on whose death in 1807 the male line of James II. came to an end. Henry was also the last descendant in the lineal male line of any of the crowned heads of the race, so far as either England or Scotland was concerned. In the female line, however, there are among the descendants of James I. representatives of the royal Stuarts who are senior to the house of Hanover, for Philip, duke of Orleans (brother of Louis XIV), married, as his first wife, Henrietta, daughter of Charles I., and, as his second, Charlotte, granddaughter and heiress of the princess Elizabeth (daughter of James I.). By the former, through their daughter, the queen of Sardinia, he was ancestor, among others, of the princess Maria Theresa of Bavaria, who in 1910 was "heir of line" of the house of Stuart, her eldest son, Prince Rupert, being at that time heir to the throne of Bavaria.

Abstract of the Evidence to Prove that Sir William Stewart of Jedworth, the Paternal Ancestor of the Present Earl of Galloway, was the Second Son of Sir Alexander Stewart of Darnley (1801); Riddell, *Stewartiana* (1843); W. Townend, *Descendants of the Stuarts* (1858); R. W. Eyton, *History of Shropshire* (1858), vol. vii.; Bailey, *The Succession to the English Crown* (1879); Skelton, *The Royal House of Stuart* (1890); J. H. Round, *Studies in Peerage and Family History* (1901); S. Cowan, *The Royal House of Stuart* (1908); and T. F. Henderson, *The Royal Stewarts* (1914). The best chart pedigree of the house is that which was prepared for the Stuart Exhibition by W. A. Lindsay.

STEWART, SIR DONALD MARTIN (1824–1900), British field marshal, son of Robert Stewart of Forres, Elginshire, was born at Mount Pleasant, near Forres, on March 1, 1824. He entered the Bengal army in 1840, and served in 1854 and 1855 in the frontier expeditions against the Mohmands, and Afridis Aka and Bari Khel (medal and clasp). In the Indian Mutiny in 1857 Stewart, after a famous ride from Agra to Delhi with despatches, served on the staff at the siege and capture of Delhi and Lucknow, and afterwards through the campaign in Rohilkhand. For nine years he was assistant and deputy-adjutant-general of the Bengal army, commanded the Bengal brigade in the Abyssinian expedition in 1867, and became a major-general in 1868. He reorganized the penal settlement of the Andaman Islands, where he was commandant when Lord Mayo was assassinated, and, after holding the Lahore command, was promoted lieutenant-general in 1877, and commanded the Kandahar field force in the Afghan War in 1878. On hearing of the Maiwand disaster he despatched Roberts with a division on his celebrated march from Kabul to Kandahar, and himself led the rest of the army back to India by the Khyber Pass. Promoted general in 1881, he was for five years commander-in-chief in India, and afterwards member of the council of the secretary of state for India until his death. He was promoted to be field marshal in 1894, and appointed governor of Chelsea Hospital in 1895. He died at Algiers on March 26, 1900.

See G. R. Elsmie, *Sir Donald Stewart* (1903).

STEWART, DUGALD (1753–1828), Scottish philosopher, was born in Edinburgh on Nov. 22, 1753. His father, Matthew Stewart (1715–1785), was professor of mathematics in the university of Edinburgh (1747–1772). Dugald Stewart was educated at Edinburgh and Glasgow. At 19 he acted as substitute for his father in the chair of mathematics at Edinburgh. From 1785 to 1820 he was professor of moral philosophy in the university, though he retired from the active duties of the chair after the death (1809) of his second son, which was a great blow to him. He died at Edinburgh on June 11, 1828.

Stewart's principal work is *Elements of the Philosophy of the Human Mind* (3 vols. 1792, 1814, 1827). He also wrote *Philosophical Essays* (1810), and *The Philosophy of the Active and Moral Powers* (1828). His philosophical views are mainly the reproduction of those of his master Reid.

STEWART, SIR HERBERT (1843–1885), British soldier, born on June 30, 1843, at Sparsholt, Hampshire, was educated at Winchester and entered the army in 1863. Returning from service in India in 1873, he entered the staff college and the Inner Temple. He served in South Africa in the Zulu War and against Sikukuni, and was present at Majuba (1881), where he was made prisoner for a month. In Aug. 1882 he was placed on the staff of the cavalry division in Egypt, and took possession of Cairo after Tel-el-Kebir (Sept. 13, 1882). In 1884 he commanded the cavalry under Sir Gerald Graham at Suakin. For his services in Egypt he was made K.C.B., and was assistant adjutant and Q.M.G. in the south-eastern district in England (April–Sept. 1884). He then joined the expedition for the relief of Khartoum, and commanded the relief column sent by Lord Wolseley across the desert of Metemma. On Jan. 17, 1885, he repulsed an enemy charge near Abu Klea. He was promoted major-general, but died on the way back from Khartoum to Korti, on Feb. 16, 1885, and was buried near the wells of Jakdul.

STEWART, WILLIAM (*c.* 1480–*c.* 1550), Scottish poet and translator, descendant of one of the illegitimate sons of Alexander Stewart, earl of Buchan, the "Wolf of Badenoch," was a member of the university of St. Andrews. He was in orders, and a hanger-on at the court of James V. Portions of his minor verse are preserved in the Bannatyne and Maitland Folio MSS. His chief work is a metrical translation of Hector Boece's *History*, in obedience to the command of James V., who entrusted Bellenden with its translation into Scots prose.

Stewart's version remained in ms. till 1858, when it was edited by W. Turnbull for the "Rolls Series" (3 vols.). The ms. is now in the library of the university of Cambridge.

STEWART, SIR WILLIAM (*c.* 1540–*c.* 1605), Scottish politician, began life as a soldier in the Netherlands, where he became a colonel. In 1582 he was in Scotland, where James VI. made him captain of his guard. Having visited the English court in the king's interest in 1583, Stewart helped to free James from William Ruthven, earl of Gowrie, and to restore James Stewart, earl of Arran, to power; he was made a privy councillor and for a time assisted Arran to govern Scotland. In 1584 he captured Gowrie at Dundee. In 1594 he was knighted and was given lands at Houston. He died before 1606.

STEWART, WILLIAM DOWNIE (1878–), New Zealand politician and publicist, was born at Dunedin on July 29, 1878, his father being a member of the legislative council. In 1914 he entered parliament as member for Dunedin West. A period of war service with the Otago regiment in 1916–17 interrupted his political career, but he was re-elected in 1919 and in 1922 joined the Massey ministry as minister for industries and commerce. From 1926 onwards he was attorney-general, minister of finance, of stamp duties, etc. In 1926 he was acting prime minister. He is joint author (with Professor Le Rossignol) of *State Socialism in New Zealand* (1910).

STEYN, MARTINUS THEUNIS (1857–1916), last president of the Orange Free State, was born at Winburg in that State on Oct. 2, 1857. He was a student in Holland and later in England at the Inner Temple, and was called to the English bar in Nov. 1882. After his return to South Africa he practised as a barrister at Bloemfontein, and in 1889 was appointed state attorney of the Free State. A few months afterwards he became second puisne judge, and in 1893 first puisne judge of the high court. His decisions won him a reputation for ability and sound judgment. In 1895, upon the resignation of President F. W. Reitz, Steyn was the candidate of the pan-Dutch party for the vacant post. The election resulted (Feb. 1896) in a decisive victory for Steyn. As president he linked the fortunes of his State with those of the Transvaal, a policy which led to the extinction of the republic. He took part in the peace negotiations at Klerksdorp in April 1902, but was prevented by illness from signing the instrument of surrender at Pretoria on May 31. In 1908–1909 he was vice-president of the Closer Union Convention, where he showed a conciliatory attitude.

STEYNING (stĕn′ning), town in Sussex, England, 12 m. W.N.W. of Brighton by a branch of the S.R. Pop. (1921) 1,875. The church of St. Andrew retains a series of Norman pier-arches in the nave. The Anglo-Saxon church of Steyning mentioned in Domesday is attributed to St. Cuthman, who is said to have settled here before the 9th century, and whose shrine became a resort for pilgrims. In 1086 Steyning was a thriving port, with a market, a mint and two churches. Its decay began in the 14th century owing to the recession of the sea, and it received another blow in the suppression of its priory by Henry IV.

STEYR, a town in Upper Austria at the junction of the Steyr with the Enns. The old town, dominated by a tenth century castle, occupies the peninsula between the streams. Two important new suburbs, Steyrdorf and Ennsdorf, lie across the streams. Steyr is the chief centre of the iron and steel industry of Upper Austria.

STIBNITE, a mineral consisting of antimony sulphide, Sb_2S_3, occurring as bladed or acicular orthorhombic crystals; an important ore of antimony. It was mentioned by Dioscorides and Pliny under the names *stimmi, stibi* and *platyophthalmon* (πλατυόφθαλμον); the last name refers to the use which the ancients made of the powdered mineral for darkening the eyebrows to increase the apparent size of the eyes. The Arabic name *al-kohl* (now strangely corrupted to *alcohol*) had reference to the same use. Antimonite is also a common name for this species.

The crystals are prismatic in habit, deeply furrowed longitudinally, and usually terminated by acute pyramidal planes. There is a perfect cleavage (010) parallel to the length of the crystals, and the basal plane (001) is a plane of gliding; the latter gives rise to very characteristic transverse striations or nicks on the cleavage surfaces of crystals which have been bent. The colour is lead-grey, and the lustre metallic and brilliant; crystals become dull on prolonged exposure to light. Cleavage flakes of extreme thinness transmit a small amount of red light, but are more transparent for heat rays. The mineral is quite soft (H=2), and has a specific gravity of 4·6. Stibnite occurs with quartz in beds and veins in gneisses and schists, or with blende, galena, etc., in metalliferous veins Magnificent groups of brilliant crystals, up to 20 in. in length, were formerly abundant in the antimony mine of Ichinokawa, on Shikoku island, Japan. Large, but dull, crystals have also been found at Lubilhac in Haute-Loire, France. Prismatic and acicular crystals often penetrating tabular crystals of barytes, are common at Baia Sprie in Rumania (formerly Felsőbánya, Hungary) (L. J S)

STICK-INSECT, the name given to certain orthopterous insects of the family Phasmidae, deriving their name from a resemblance to the branches and twigs on which they live and feed. The resemblance is produced by the great length and slenderness of the body and legs. Protection is afforded to some species, like *Haaniella grayi* from Borneo, by sharp thornlike spines. The anterior wings, when present, are small; but the posterior wings are sometimes large and beautifully coloured The colouring, however, is only visible when the wings are expanded and in use. Many species are wingless at all ages. As in the leaf-insects, to which the stick-insects are closely allied, the egg cases are very similar to seeds. Stick-insects attain their largest size and greatest profusion of species in the tropics, one N. Queensland species, *Palophus titan,* reaching a length of 10in. Species of small size are found in southern Europe one belonging to the genus *Bacillus* advancing as far north as the middle of France. They freely regenerate their legs and antennae when amputated. In certain conditions the stump of an amputated antenna will regenerate a leg (*see* REGENERATION IN ANIMALS)

STICKLEBACK, a group of small fishes (*Gasterosteus*) which inhabit the fresh and brackish waters as well as the coasts of the temperate zone of the northern hemisphere. The majority have a compressed well-proportioned body, which in the marine species is of a more elongate form. Their mouth is of moderate width, oblique, and armed with small teeth The head is protected by hard bone. There are a series of scutes protecting the sides. The first dorsal fin and the ventrals are transformed into pointed formidable spines, and joined to firm bony plates of the endoskeleton. A remarkable degree of variability is shown by many species. Sticklebacks construct a nest for the reception of the spawn, which is jealously guarded by the male until the young are hatched, from ten to eighteen days after oviposition. He also protects them for the first few days of their existence.

Sticklebacks are short-lived animals said to reach an age of three or four years In spring each male selects a territory, which he fiercely defends and to which he invites all females, until the nest is filled with ova. At this period he assumes a dress of blue and red The eggs are comparatively large, one female depositing from 50 to 100

The three-spined stickleback (*G. aculeatus*) is found everywhere in northern and central Europe, northern Asia, and North America.

The ten-spined stickleback (*G. pungitius*) is smaller than the three-spined species, rarely exceeding 2in. in length. Its geographical range nearly coincides with that of the other species.

The sea-stickleback (*G. spinachia*) attains a length of 7in., and is armed with 15 short spines. It is common round the British coasts. At suitable localities which are sheltered from the waves and overgrown with seaweed, especially in rock-pools and shallows covered with *Zostera,* one or two males establish themselves with their harems. The nest is firmly attached to seaweed.

STIGAND (d 1072), archbishop of Canterbury, is first mentioned in 1020. He was then chaplain to Canute and afterwards to his son, Harold Harefoot, and after the death of Canute appears to have acted as the chief adviser of his widow, Emma. In 1043 he was consecrated bishop of Elmham and in 1047 was translated to Winchester; he supported Earl Godwine in his quarrel with Edward the Confessor, and in 1052 arranged the peace between the earl and the king. In this year the archbishop of Canterbury, Robert of Jumièges, having been outlawed, Stigand was appointed to the archbishopric; but Pope Leo IX. and his two successors refused to recognize him. In 1058, however, Benedict X gave him the pall, but this pope was deposed in the following year. Stigand is said by Norman writers to have crowned Harold in Jan. 1066; but this ceremony was probably performed by Aldred, archbishop of York. Stigand submitted to William, and assisted at his coronation. But the Conqueror was anxious to get rid of him. In 1070 he was deposed by the papal legates and was imprisoned at Winchester, where he died, probably on Feb 22, 1072. Stigand was an avaricious man and a great pluralist, holding the bishopric of Winchester after he became archbishop of Canterbury, in addition to several abbeys

See E. A. Freeman, *The Norman Conquest* (1870–76), vols ii, iii. and iv.; and J. R. Green, *The Conquest of England* (1899), vol. ii.

STIGMATIZATION, the infliction of *stigmata,* used with specific reference to the supposed supernatural infliction of wounds like those of Christ.

In St. Francis of Assisi we have the first example of the alleged miraculous infliction of stigmata. Remembering the sufferings of our Lord, in his cell on Mount Alverno in 1224, we are told by his biographers, Thomas of Celano and Bonaventura, that the Lord appeared to Francis as a seraph and produced upon his body the five wounds of Christ; of these we are told that the side wound bled occasionally, though Bonaventura calls it a scar, and the wounds in the feet had the appearance and colour of nails thrust through. After his death St. Clare endeavoured, but in vain, to extract one of these. Pope Alexander IV and other witnesses declared that they had seen these marks both before and after his death. The divinely attested sanctity of their founder gave to the newly established order of Franciscans a powerful impulse, so that they soon equalled and threatened to overshadow in influence the previously founded order of St. Dominic.

The reputation of the latter order was, however, similarly raised in the next century by the occurrence of the same wonder in the case of a sister of the third rule of St. Dominic, Catherine Benincasa—better known as St. Catherine of Siena. From her biographer's account we gather that she was subject to hystero-epileptic attacks In one of these attacks, when she was twenty-three years old, she received the first stigma. In spite of her great reputation, and the number of attesting witnesses, this occurrence was not universally believed

The instances of masculine stigmatization are few. Benedict di Rhegio, a Capuchin at Bologna, had the marks of the crown (1602); Carolus Sazia, an ignorant lay brother, had the wound in his side Dodo, a Praemonstratensian lay brother, was fully stigmatized, as also was Philip de Aqueria The marks after death were found on the heart of Angelos del Pas, a minorite of Perpignan, as also on Matheo Carery in Mantua, Melchior of Arazel in Valentia, Cherubin de Aviliana (an Augustinian), and Agolini of Milan. Walter of Strassburg, a preaching friar (1264), had the heart-pain but no mark, and the same was the case with a Franciscan, Robert de Malatestis (1430), and James Stephanus. On Nicholas of Ravenna the wounds were seen after death, while John Gray, a Scotsman and Franciscan martyr, had one wound on his foot.

Several later instances have been recorded. Anna Katherina Emmerich, a peasant girl born at Münster in 1774, afterwards an Augustinian nun at Agnetenberg, was even more famous for her visions and revelations than for the stigmata. Biographies, with records of her visions, have been published by Brentano at Munich in 1852 and the Abbé Cazalès at Paris (1870). Colombe Schanolt of Bamberg (1787) was fully stigmatized, as also was Rose Serra, a Capuchin of Ozieri in Sardinia (1801), and Madeleine Lorger (1806).

The last case recorded is that of Louise Lateau, a peasant girl,

at Bois de Haine, Hainault, upon whom the stigmata appeared on the 24th of April, 1868. This case was investigated by Professor Lefebvre of Louvain, who for fifteen years was physician to two lunatic asylums. In her there was a periodic bleeding of the stigmata every Friday, and a frequent recurrence of the hystero-cataleptic condition. Her biography has been written by Lefebvre and published at Louvain (1870).

Cotelle, *St. François* (1895). (2) On the general subject: A. Imbert-Gourbeyre, *Les stigmatisées* (2nd ed. 1886); *La stigmatisation* (1894); J. J. von Görres, *The Stigmata* (Eng. tr. 1883).

STILBENE, a glistening colourless crystalline hydrocarbon melting at 124° C, and boiling at 306° C, and soluble in alcohol or ether. It is prepared either by the action of sodium on benzylidene (benzal) chloride, $C_6H_5{\cdot}CHCl_2$, or by passing toluene over heated lead oxide. Stilbene is symmetrical diphenylethylene, $C_6H_5{\cdot}CH{:}CH{\cdot}C_6H_5$, and many of its derivatives are known to exist in two structural forms exhibiting stereoisomerism of the type shown by fumaric and maleic acids. It is chiefly of interest as being the basis of several important synthetic dyes. *Stilbene azo-dyes,* 4:4′-Diaminostilbene-2:2′-disulphonic acid, $NH_2{\cdot}C_6H_3(SO_3H)CH{:}CH{\cdot}C_6H_3(SO_3H){\cdot}NH_2$, prepared from *para*-nitrotoluene*ortho*sulphonic acid by successive treatment with aqueous caustic soda and alkaline zinc dust, when diazotised and coupled with β-naphthylamine and its sulphonic acids, furnishes substantive cotton dyes known as Hessian Purples M.

Stilbene colours.—Various cotton yellows and oranges are obtained by boiling *p*-nitrotoluene-*o*-sulphonic acid with aqueous caustic soda alone (Chlorazol yellow), in the presence of oxidisable substances such as glycerol, sodium sulphite, or gallic acid (Chlorazol Fast Orange) or with oxidising agents such as sodium hypochlorite (Chlorazol Fast Yellow).

Diphenylacetylene or *tolane,* $C_6H_5{\cdot}C{:}C{\cdot}C_6H_5$, colourless crystals melting at 60° C, results from the action of alcoholic potash on stilbene dibromide. (G. T. M.)

STILBITE, a mineral of the zeolite group consisting of hydrated calcium aluminium silicate, $CaAl_2(SiO_3)_6+6H_2O$. Usually a small proportion of the calcium is replaced by sodium. Crystals are monoclinic, and are invariably twinned, giving rise to complex groups and characteristic sheaf-like aggregates. The colour is usually white, sometimes red, and on the perfect cleavage (parallel to the plane of symmetry) the lustre is markedly pearly; hence the name stilbite (Gr. στίλβειν, to shine) given by R. J. Haüy in 1796. After the separation of heulandite from this species in 1818, the name desmine (δέσμη, a bundle) was proposed, and this name is now employed in Germany. The hardness is 3·5 and the specific gravity 2·2. Stilbite occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks; it is sometimes found in granite and gneiss, and exceptionally in metalliferous veins. Beautiful, salmon-pink crystals occur with pale green apophyllite in the Deccan traps near Bombay and Poona; white sheaf-like groups encrust the calcite (Iceland-spar) of Berufjord near Djupivogr, Iceland; and crystals of a brick-red colour are found at Old Kilpatrick, Dumbartonshire.

STILES, EZRA (1727–1795), American clergyman and educationalist, seventh president of Yale college, was born on Nov. 29, 1727 in North Haven, a parish of New Haven (Connecticut). He graduated at Yale in 1746; was licensed to preach in 1749 and was a tutor at Yale in 1749–55. He also preached in 1750 to the Indians at Stockbridge, was admitted to the bar in 1753, and practised in New Haven for two years. After pastorates at Newport (R.I.) and Portsmouth (N.H.) he became in 1778 president of Yale college and professor of ecclesiastical history, becoming for a few years after 1780 professor of divinity and lecturing on many subjects. He died in New Haven on May 12, 1795. His wise administration as president made possible the speedy recovery of Yale college after the War of Independence; his intellectual and theological breadth helped to secularize and strengthen the college. He carefully kept thermometric and meteorological statistics; he imported silkworms and books on silk culture; he corresponded with many litterati; he undertook the study of Hebrew at the age of 40 and became an able scholar; in short, his hunger for knowledge was insatiable. On Franklin's recommendation he was made a doctor of divinity by the University of Edinburgh in 1765, and he was awarded other honorary degrees in his own country. Dr. Stiles published a number of sermons, an *Account of the Settlement of Bristol, Rhode Island* (1785); and a *History of Three of the Judges of King Charles I.* (1794). His *Literary Diary* (3 vol., 1901) was edited by F. B. Dexter, who quotes largely from Dr. Stiles's *Itineraries. Extracts from the Itineraries and Other Miscellanies* with selections from Dr. Stiles's correspondence prepared by the same editor appeared in 1916. Both give a valuable picture of New England life and contemporary figures.

See the *Life of Ezra Stiles* (1798), by his daughter's husband, Abiel Holmes, the father of Oliver Wendell Holmes, and the life by J. L. Kingsley in Jared Sparks, *American Biography* (ser. 2, vol. vi., 1845).

STILICHO, FLAVIUS (?–408), Roman general and statesman, was the son of a Vandal who had served as an officer in the army of the emperor Valens (364–378). He himself entered the imperial army at an early age and speedily attained high promotion. He had already become master of the horse when in 383 he was sent by Theodosius (379–395) at the head of an embassy to the Persian king, Sapor III. His mission was very successful, and soon after his return he was made count of the domestics and received in marriage Serena, the emperor's niece and adopted daughter. In 385 he was appointed master of the soldiery in Thrace, and shortly afterwards directed energetic campaigns in Britain against Picts, Scots and Saxons, and along the Rhine against other barbarians. Stilicho and Serena were named guardians of the youthful Honorius when the latter was created joint emperor in 394. Rivalry had already existed between Stilicho and Rufinus, the praetorian praefect of the East. Consequently in 395, after a successful campaign against the Germans on the Rhine, Stilicho marched east, with the design of displacing Rufinus; and by connivance with the barbarians he procured the assassination of Rufinus at the close of the year, and thereby became virtual master of the empire. In 396 he fought in Greece against the Visigoths, but an arrangement was effected whereby their chieftain Alaric was appointed master of the soldiery in Illyricum (397). In 398 he quelled Gildo's revolt in Africa and married his daughter Maria to Honorius. Two years later he was consul. He thwarted the efforts of Alaric and Radagaisus to seize lands in Italy by his victories on the Danube at Pollentia and Verona in 401–3.

In a second campaign against Radagaisus, who led a large force of various Germanic peoples into Italy in 405, he surrounded the barbarian chieftain on the rocks of Fiesole and starved him into surrender. Early in 408 he married his second daughter Thermantia to Honorius. It was rumoured about this time that Stilicho was plotting with Alaric and with Germans in Gaul and taking other treasonable steps in order to make his own son Eucherius emperor. The facts are doubtful. It is certain, however, that he was suspected by Honorius and abandoned by his own troops, and that he fled to Ravenna, and, having been induced by false promises to quit the church in which he had taken sanctuary, was executed on Aug. 23, 408.

The principal sources for the life of Stilicho are the histories of Zosimus and of Orosius and the flattering verses of Claudian. *See* T. Hodgkin, *Italy and her Invaders,* vols. i. and ii. (Oxford, 1880); E. Gibbon, *Decline and Fall of the Roman Empire,* edited by J. B. Bury, vol. iii. (1902); P. Villari, *The Barbarian Invasions of Italy,* translated by L. Villari, vol. i. (New York, 1902); S. Dill, *Roman Society in the last century of the Western Empire* (1899); Mommsen in *Hermes* xxviii.; and K. Birtin, *Spätrömische Charakterbilder* (Leipzig, 1919).

STILL, ANDREW T. (1828–1917), founder of osteopathy, was born in Jonesboro, Va., on Aug. 6, 1828. His family moved in 1837 to Macon county, Missouri, and later to the Shawnee

reservation near Kansas City, Kansas. Still took an active part in settling the slave question in Kansas, and in 1847 was elected to the Kansas State legislature on the Free State ticket. He began searching for other means than medicine to combat disease and formulated his principles of osteopathy in 1874. He underwent a long period of opposition, but finally, in 1892, founded the American School of Osteopathy at Kirksville, Mo., in conjunction with William Smith, a Scottish physician. In 1922 the Andrew T. Still College of Osteopathy and Surgery was founded and merged with the original American school. He was the author of *The Philosophy of Osteopathy* (1899), *Autobiography of Andrew T. Still* (1897) and *Osteopathy, Research and Practice* (1910).

See "Andrew T. Still," *Missouri Historical Review*, vol. xix., 1924.

STILL, JOHN (1543?–1608), bishop of Bath and Wells, was born at Grantham, Lincs. He studied at Christ's college, Cambridge, becoming in 1561 a fellow of his college, and took holy orders. He was appointed in 1570 Lady Margaret professor of divinity, subsequently held livings in Suffolk and Yorkshire, and was master successively of St. John's College (1574) and of Trinity College (1577). Still was vice-chancellor of his university in 1575–76 and again in 1592–93, and was raised to the bishopric of Bath and Wells in 1593. He died on Feb. 26, 1608, leaving a large fortune from lead mines discovered in the Mendip Hills. He was for some time generally believed to be the author of the English comedy *Gammer Gurton's Needle,* which is now ascribed to William Stevenson (*q.v.*)

STILL ENGINE: *see* INTERNAL COMBUSTION ENGINE.

STILLINGFLEET, EDWARD (1635–1699), English divine, was born at Cranborne, Dorset, on April 17, 1635 He graduated from St. John's college, Cambridge, in 1652, and in the following year was elected to a fellowship. At Sutton, Beds., of which he was vicar, he published (1659) his *Irenicum* in which he sought to give expression to the prevailing weariness of the faction between Episcopacy and Presbyterianism, and to find some compromise. He looks upon the form of church government as non-essential, but condemns Nonconformity. Although in 1680 he published his *Unreasonableness of Separation,* his willingness to serve on the ecclesiastical commission of 1689, and the interpretation he then proposed of the damnatory clauses of the Athanasian creed, are proof that to the end he leaned towards toleration. His rapid promotion dates from 1662, when he published *Origines sacrae, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained.* In 1665 the earl of Southampton presented him to St. Andrew's, Holborn, two years later he became prebendary of St Paul's, in 1668 chaplain to Charles II., in 1670 canon residentiary, and in 1678 dean of St. Paul's. He was also preacher at the Rolls Chapel and reader at the Temple. Finally he was consecrated bishop of Worcester on Oct. 13, 1689. During these years he was ceaselessly engaged in controversy with Nonconformists, Romanists, Deists and Socinians. His various learning, his dialectical expertness, and his massive judgment, rendered him a formidable antagonist; but the respect entertained for him by his opponents was chiefly aroused by his recognized love of truth. He was one of the seven bishops who resisted the proposed Declaration of Indulgence (1688). The range of his learning is most clearly seen in his *Bishop's Right to Vote in Parliament in Cases Capital.* His *Origines Britannicae, or Antiquities of the British Church* (1685), is a strange mixture of critical and uncritical research. In his closing years he had some controversy with John Locke, whom he considered to have impugned the doctrine of the Trinity. He died at Westminster on March 28, 1699.

A collected edition of his works, with life by Richard Bentley, was published in London, 6 vols (1710); and a useful edition of *The Doctrines and Practices of the Church of Rome Truly Represented* was published in 1845 by William Cunningham.

STILL-LIFE PAINTING, the art of painting inanimate objects for their beauty of colour, line or arrangement. It was first developed as an individual branch of easel painting by the artists of the Netherland school of painters. Families of artists chose this simple line of art for their life's work. Gold and silver cups, flagons and plates of porcelain and delft, oriental rugs and draperies, Venetian and Bohemian glass richly ornamented, and even jewels, scientifically arranged for scintillating effects, were motifs for some of the most brilliant artists. Simple kitchen utensils of brass and copper, with meat, fish and vegetables, made fine subjects for colour and line. The sparkle of metals, the glitter of wet fish, the deep and rich tones of meat and vegetables—what better material could the painter desire!

Exquisite drawing, with painstaking draughtsmanship as a primary factor, resulted in paintings that were sought not only by the rich burghers, but by visiting princes and ambassadors. In every museum may be found these masterpieces, and although not so numerous as the many rows of portraits, *genre* and religious canvases, they, nevertheless, hold their high place in Dutch art.

The Flemish and Dutch artists felt, and so did many true lovers of the fine arts of that time, that the subject of a picture was not the only motif worth while; that an arrangement beautifully composed, either for luxurious abundance or for simplicity in colour, tone, values and line, would make a noble work of art, in spite of what higher thought might find in portraying character in the portrait and deep feeling in the religious picture. They argued that a well painted still-life was a greater art production than a badly painted Madonna, however well conceived.

Subject-matter.—Pictures of the life of the people themselves, their houses, gardens, the interior of the splendidly furnished homes of merchants and aristocrats, rich in hangings and elaborate in table service, made beautiful settings for the painter. The everyday life of the people around the artist showed him just what he wanted. Besides, it furnished a subject that was simpler to do than the literary picture, as well as being more straightforward and true. People in silk and velvet, visiting in well-appointed rooms to listen to music or to partake of wine and cake or fruit, served on silver or choice porcelain, were none the better as subjects than a girl scouring a brass kettle in the kitchen.

That greatest part of the painter's knowledge, the observation of values, which means rendering the lights and shadows of a subject regardless of local colour, was first thoroughly understood by these artists, and is the basis of all sound painting. From the work of these men, still-life developed. The principle is the same, the interiors being to a great extent still-life There is usually very little expression or movement needed for the figures. However well painted the heads, the clothes, even the glass of amber-coloured wine in the lady's hand, seem almost of the same interest as the head. Take the figures out and the pure still-life is the result. The simple composition of a few peaches on a piece of delft with a silver pitcher and an ornamented glass half full of wine is all that a master like Willem Kalf needs to make a supreme painting.

Technique.—Often in the galleries and at exhibitions, critical visitors, some of whom are professional painters, ask: "What is still-life?" Reproducing the roundness and firmness of a red apple is not very different from the modelling of a head. Lovers of painting look for something different in a canvas, something that for them means beauty or truth—and not every one sees the same beauty in a picture painted by a master. Take Velázquez' "Aguador" for an example; to the painter, a quiet study of modelling, with remarkable still-life; to one with perhaps no ability as a painter, a thoughtful study of a man's head; to another a beautiful head of a boy. Velázquez had a number of interesting still-life pictures. In "The Steward" and "Old Woman Frying Eggs," each has a single figure in the composition, but the pictures are evidently made for close studies of inanimate life, dead fish, meat, jars and glass, masses of objects, scattered all over the canvas. Rembrandt's "Flayed Ox" in the Louvre is a great example of noble quality, rich in colour, bold in treatment, closely observed in values, and of great simplicity—a masterpiece.

Pieter Aertsen, early 16th century, one of the first absolute still-life painters, although at times introducing figures in the background of some of his pictures, painted pictures of meats, vegetables, etc., in the kitchen or larder. His large canvas in Uppsala, representing a butcher-shop with a calf's head, a side of beef, a pig's head and sausages, fowl, fish and all sorts of gruesome details of what one expects to find in such a place, is typical. The canvas is overfilled, every small place is crowded, and

STILL-LIFE PAINTINGS

1. "Flayed Ox," by Rembrandt (1606–1669). Bold treatment, rich colour, values closely observed. Now in Louvre. 2. "Aguador de Sevilla" by Velasquez (1599–1660). Quiet study of modeling. In collection of His Grace the Duke of Wellington. 3. "La Fontaine," superb canvas, one of Chardin's favourite works. Chardin (1699–1779) was able to see and reproduce beauty in simple utensils of the kitchen. In Metropolitan Museum. 4. Chardin's "La Pourvoyeuse," one of the three most famous paintings by this master of still life; light, colour and harmony emphasized. Now in Louvre. 5. Still life by Emil Carlsen (1853–   ), meticulous attention paid to the small details. 6. "Le Gallant Militaire," by Ter Borch (1617–1681). Painted in the adopted style of the Dutch. Values and tonality closely observed. In Louvre

FISH, FRUIT, AND GAME

1. "Still Life" by Willem Kalf (1622–93), who needed only the simple composition of a few peaches, a pitcher and an ornamental wine glass to make a masterpiece. Dutch
2. "Large Still Life With Bird's Nest" by Jan Davidsz Van Heem (1606–84). Dutch. Van Heem's pictures are drawn and coloured exquisitely. His use of chiaroscuro was very effective
3. "Still Life," one of Antoine Vollon's pictures (1833-1900). French. Most of this painter's work was done in one sitting. He painted somewhat after the Dutch manner. In the Louvre
4. "Lobster, Fruit and Flowers" by Cornelius Van Heem (1631–95), son of Jan Davidsz Van Heem. Dutch
5. "Study of Still Life" by Frans Snyder (1579–1657). Flemish. Snyder painted many typical models of still life during the early part of his career. In the Rijks Museum
6. A Still Life by Jean Baptiste Siméon Chardin (1699–1779) depicting a bowl of fruit and a pitcher. Every colour value is observed. Now in Phillips Memorial Gallery, Washington, D.C. French
7. "Fish on a Table" a still life by Alexander Adriaenssen (1587–1661). German

BY COURTESY OF (1) THE RIJKS MUSEUM, (2, 4) THE METROPOLITAN MUSEUM OF ART, NEW YORK, (3) THE UNIVERSITY OF UPPSALA

EXAMPLES OF STILL-LIFE ART

1. "Fruit and Game" by Jan Weenix (1640–1719), highly decorative, luxurious surroundings, garden background. Dutch. In Rijks Museum
2. "Dead Game" by Jan Fyt (1611–61), pupil of Franz Snyder (1579–1657), realistic in quality of the painting of the feathers. In The Metropolitan Museum of Art, New York
3. "The Butcher Shop" by Pieter Aertsen (1507-73). Fine quality, excellent perspective, gruesome details have not been overlooked.
4. "Fish," a still-life painting by William Chase (1849–1916), American. In the Metropolitan Museum of Art, New York

ARTISTIC STILL-LIFE CANVASES

1. "Kitchen Table" by Jean Baptiste Siméon Chardin (1699–1779); splendid handling of white pigment, as shown in treatment of white jug and fowl. French. Museum of Fine Arts, Boston
2. "The Table" by André Derain (1880–), who combined the influence of Cézanne and Gauguin with the primitive. French
3. "Hearthstone" by Emil Carlsen (1853–), characterised by simplicity of treatment and faithful portrayal of homely utensils. American
4. "Fish" by Henri Matisse (1869–), noted for sureness and simplicity in his drawings. French. In the Tate Gallery, London

although correct in drawing, well coloured and a picture most interesting, it is in questionable taste.

Abraham van Beyeren (1620–75) stands out as one of the foremost painters of fish, producing well composed paintings, glowing with bright colours and glistening surfaces. The painting of wet, sparkling fish gives opportunities to the student for the study of brilliant light against the deep and rich notes in the wet fish, and as the fish very soon deteriorates in colour and form, the canvas must be painted quickly, in the heat of enthusiasm, thus bringing forth the finest results, the most spontaneous work.

Joachim Buckelaer painted fish, as did Alexander Adriassen and, in their late years, Vollon, Manet and Chase.

Jan Davidszoon de Heem and his son, Cornelius de Heem, the two most celebrated members of a large family of still-life painters, are separately noticed. Jan was one of the earliest and ablest. The realism of the individual flower or peach was more desired by these painters than the ensemble of the picture. Jan van Huysum (*q.v.*) reached the top as a flower painter whose style was similar to that of the de Heems.

Willem Kalf, like Willem Claesz Heda, had finer perception of tone and envelopment. Both were painters of rich objects that were executed in the adopted style of the Dutch, but with keen observation of values and tonality; they were taught by masters like Vermeer and Terborch.

Franz Snyders's large game compositions are highly decorative, his fruit rich in colour, well drawn and painted, but overfilled with details and without concentration of the motif. No air in them! The pictures of game that his pupil, Jan Fyt, painted are well studied, realistic in the weight of deer and hare, and in the quality of the painting of fur and feathers. Jan Weenix was a highly decorative painter of dead game in luxurious surroundings, garden backgrounds with decorated vases, the implements for the hunt and its spoils.

In all this interesting still-life work it was always the manner that was considered superior to the matter, and it was always the school that called for excellence of craftsmanship. Every master had his pupils who followed his style; father taught son, and the son taught his son; it was a trade that had to be learned.

Without absolute knowledge of his tools and the preparation of the canvas or panel, one did not count for much in the craft. So-called "visions" were not considered in the Netherlands, as they were in Italy. Pictures that could be studied and loved at short range were called for, and the work could not be carelessly done. Therefore, something was often missing, even in this beautiful work. It left no room for imagination. It was only for the eye—charming to look at, but nothing to dream about—and was generally the work of the painter and rarely of the artist.

Chardin.—Jean Baptiste Simeon Chardin lifted still-life to a higher plane in art than the Hollanders and Flemings of former years. Understanding their methods, he added to their technique air and light as the aim to search for. His simplicity saw beauty in his daily surroundings; his honesty rendered them with absolute truth. Every utensil in his kitchen we know—the copper water-fountain, the charcoal brazier, the brass kettles, the handsome water-jar, the bread knife, as well as the large loaf of bread, the herrings, cuts of meat, onions and pieces of china. Chardin's living-room we know, with the straight-backed chairs and the bird in its cage on a stand. We know the housewife with her white apron—and how splendid a white! Chardin's whites are miracles of painting. The white jug and the white fowl in the still-life in the Boston museum are unequalled. Few painters of all time have been able to handle white pigment as Chardin could. J. G. Whistler was among the few.

Among his earliest pictures was the "Skate," now in the Louvre. This was accepted by the academy as his diploma picture, simply painted and freer in treatment than other canvases of his early career. He painted a great many interiors, with one or two figures. Again and again it is the light that predominates, the atmosphere of the room or rooms, for we often look through an open door into another room, and that room full of light. Every figure has its weight, stands soundly on its feet and is well in its distance from the onlooker and from the wall behind. As still-life painting or interior with figure, it has every quality known; every colour value is observed, the drawing is easy, never overdrawn, and still never slighted. Chardin's textures are rendered as only a master could paint them; metal is metal and cloth is cloth; every edge, the despair of the average painter, is firm but well blended; light and air are over and around every figure or object. This is still-life painting, an answer to "What is still-life?"

Later Still-life Artists.—Chardin died in 1779, and for nearly a century there were no still-life painters of note; there was practically no interest in *nature morte*. When Courbet started his bold and vigorous manner of painting, he was alone; he painted what he saw and in a manner of his own invention. Whatever in nature looked worth painting he painted—figures, landscape, marines and still-life. His still-life canvases are done truthfully and spontaneously, and are of a flat, well-coloured technique. Several of his pictures have a stag in them, similar in motion to those of Snyders or Weenix, but with more weight and greater originality.

Manet was an artist who painted for excellence, and his still-life work, of which he did a great deal, is always of a high order. Simple and full of light, the canvas is never overfilled. Manet was also an individual who saw with his own eyes and painted in a flat manner, local colour and values being purposely slighted.

Antoine Vollon painted landscapes, but is better known for his still-life, in which he was very prolific. Most of his work was done in one sitting, and in a decorative, well-arranged, somewhat Dutch manner. His picture of "Fish" in the Luxembourg is a splendid piece of painting, with its dark shadows, almost monotone, and the wet and slimy fish in brilliant light. His reputation was widespread while he was alive, but seems somewhat duller at present; however, it will likely come back again, as in the case of Chardin.

Bonvin and Fantin-Latour were men of well-merited reputation. Fantin-Latour's flower paintings are tastefully arranged and finely executed. Bonvin's work, simple and truthful, is based on Chardin's methods.

Of the American painters, William M. Chase (1849–1916) painted fish, pots and brass kettles, and pictures of great brilliancy. Julian Alden Weir's flowers are noted for their exquisite delicacy and beauty. (*See* also PAINTING; FLOWER PAINTING.)

STILLMAN, WILLIAM JAMES (1828–1901), American painter and journalist, was born at Schenectady (N. Y.), June 1, 1828. He graduated at Union college, Schenectady, in 1848. He studied art under Frederick E. Church and early in 1850 went to England, where he fell so much under the influence of Rossetti and Millais that on his return home in the same year he speedily became known as the "American Pre-Raphaelite." He studied art under Yvon in Paris, returned to the United States and devoted himself to landscape painting on Upper Saranac Lake in the Adirondacks and in New York City, where he started the *Crayon*. When it failed for want of funds, Stillman removed to Cambridge, Massachusetts. He returned to England, and afterwards painted with Ruskin in Switzerland. He was in Normandy in 1861 when the American Civil War broke out. His health was too weak for him to serve in the Northern ranks and he was appointed United States consul in Rome. In 1865 he resigned, but immediately afterwards he was appointed to Crete. He was an editor of *Scribner's Magazine* for a short time. When in London lived with D. G. Rossetti. When the insurrection of 1875 broke out in Hercegovina he went there as a correspondent of *The Times*, and his letters from the Balkans aroused so much interest that the British government was induced to lend its countenance to Montenegrin aspirations. In 1877–83 he served as the correspondent of *The Times* at Athens; in 1886–98 at Rome. After his retirement he lived in Surrey, where he died on July 6, 1901. He wrote *The Cretan Insurrection* 1866–1868 (1874), *On the Track of Ulysses* (1888), *Billy and Hans* (1897) and *Francesco Crispi* (1899).

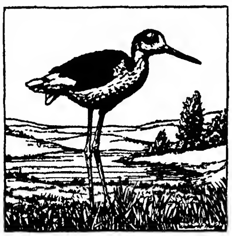
See his *Autobiography of a Journalist* (Boston, 1901).

STILLWATER, a city of eastern Minnesota, U.S.A., on the St. Croix river, at the head of Lake St. Croix, 20 m. N.E. of Saint Paul; the county seat of Washington county. It is served by the Chicago, Milwaukee, St. Paul and Pacific, the Chicago, St. Paul, Minneapolis and Omaha, and the Northern Pacific railways. Pop. (1920) 7,735; (1928 local estimate), 9,000. The city has a picturesque situation on bluffs high above the river. It is the seat of the state prison (established 1851); a shipping point for the agricultural products of the region; and a manufacturing centre of growing importance. Before the exhaustion of the forests, it had a large trade in pine lumber. Stillwater was settled in 1843, laid out in 1848, and chartered in 1854. The "Stillwater Convention" of 1848 was the first step toward the erection of Minnesota Territory.

STILO PRAECONINUS, LUCIUS AELIUS (*c.* 154–74 B.C.), of Lanuvium, the earliest Roman philologist, belonged to the equestrian order. His aristocratic sympathies were so strong that he voluntarily accompanied Q. Caecilius Metellus Numidicus into exile. At Rome he divided his time between teaching and literary work. His most famous pupils were Varro and Cicero, and amongst his friends were Coelius Antipater, the historian, and Lucilius, the satirist, who dedicated their works to him. Only a few fragments of his works remain. He wrote commentaries on the hymns of the Salii, and (probably) on the Twelve Tables; and investigated the genuineness of the Plautine comedies, of which he recognized 25, four more than were allowed by Varro. The rhetorical treatise *Ad Herennium* has been attributed to him by some modern scholars.

See Cicero, *Brutus,* 205–207, *De legibus,* ii. 23. 59; Suetonius, *De grammaticis,* 2; Gellius iii. 3, 1. 12; Quintilian, *Inst. orat.* x., 1, 99; monographs by J. van Heusde (1839) and F. Mentz (1888); Mommsen, *Hist. of Rome,* bk. iv. ch. 12, 13; J. E. Sandys, *History of Classical Scholarship* (2nd ed., 1906); M. Schanz, *Geschichte der römischen Litteratur* (1898), vol. i.; Teuffel, *Hist. of Roman Literature* (Eng. trans., 1900), p. 148.

STILT (*Himantopus himantopus*), a bird of the plover family (*see* PLOVER), remarkable for the extreme length of its slender legs. The bill is long and straight; the legs red; the wings and back black; the head, neck and lower parts white. The sexes are alike. Its food consists of small anthropods, which it obtains by wading in shallow water. It ranges over Europe and Asia, not breeding northward of the Danube valley. The nest is a slight structure on the margin of a pool or lake, and contains four eggs, which resemble those of the oyster-catcher (*q.v.*). In America, from Oregon southward to Brazil, occurs the black-necked stilt, *H. nigricollis.* Other species occur in South America, Australia and New Zealand. The stilts are allied to the avocets (*q.v.*), and, like them, spend much time wading in shallow water.



THE STILT (HIMANTOPUS HIMANTOPUS)

STILTS, poles with footrests fixed at a certain distance above the ground. They were originally designed for use in crossing rivers and marshes. As a means of amusement stilts have been used by all peoples in all ages, as well as by the inhabitants of marshy or flooded districts. The city of Namur in Belgium, which formerly suffered from the overflowing of the rivers Sambre and Meuse, has been celebrated for its stilt-walkers for many centuries. Not only the townspeople but also the soldiers used stilts. The governor of Namur having promised the archduke Albert (about 1600) a company of soldiers that should neither ride nor walk, sent a detachment on stilts, which so pleased the archduke that he conferred upon the city perpetual exemption from the beer-tax, no small privilege at that time.

The home of stilt-walking at the present day is the department of Landes in Gascony, where, owing to the impermeability of the subsoil, all low-lying districts are converted into marshes. Stilts used by children are very long, the upper half being held under the arms; they are not strapped to the leg.

STIMSON, HENRY LEWIS (1867–), American lawyer and statesman, was born in New York city on Sept. 21, 1867, and educated at Yale (A.B., 1888) and Harvard (A.M., 1889) universities. He attended the Harvard Law school and in 1891 was admitted to the New York bar. He was subsequently a member of the firms of Root and Clark, 1893–97; Root, Howard, Winthrop and Stimson, 1897–1901, and after 1901 of Winthrop and Stimson. His abilities as a lawyer brought him into prominence and in 1906 he was appointed U.S. attorney for the southern district of New York State. This position he relinquished in 1910 to become the unsuccessful candidate of the Republican party for governor of New York. In 1911 he was appointed secretary of War by President Taft, in which office he continued from May 1911 to March 1913 He subsequently resumed his law practice, which was interrupted during U S. participation in the World War by his service in France as colonel of the 31st Field Artillery. In 1927 he was sent by President Coolidge as a special commissioner to Nicaragua, where he met President Diaz and the rebel leader Moncada and was instrumental in persuading both leaders to lay down their arms on condition that the United States would supervise the 1928 election. His success on this mission, together with his study of the Philippine question in 1926, led to his appointment, in Dec. 1927, as governor-general of the Philippine Islands, in which position he succeeded Maj -gen. Leonard Wood, whose policies he continued to carry out with notable success. Early in 1929 he was appointed secretary of State by President Hoover and in March of that year he took over the duties of his new office. He is the author of *The American Policy in Nicaragua* (1927) and numerous magazine articles.

STINKHORN (*Phallus*), a genus of basidiomycete fungi, so called from the carrion-like smell of the spore-cap, which breaks down into a slimy, dripping mass Flies are attracted by the smell, and disperse the spores.

STINK-WOOD, a South African tree, known botanically as *Ocotea bullata,* and a member of the family Lauraceae. Other names for it are Cape walnut, stinkhout, Cape laurel and laurel wood. It derives its name from having a strong and unpleasant smell when freshly felled. It is used for building in South Africa and is said to be a substitute for teak and equally durable. The wood is dark walnut or reddish brown to black with a yellow sapwood, and the grain extremely fine, close, dense and smooth.

STINNES, HUGO (1870–1924), German industrialist, was born in Mülheim on Feb. 12, 1870. Educated as a mining engineer, he entered his grandfather's firm in 1890, but two years later established a business of his own, with a capital of 50,000 marks. The business expanded steadily and came to include, besides dealing in coal, the ownership of coal mines, barges, river steamers and sea-going vessels. Stinnes organized an international business in coal, including the importation of coal from England. He built up a fleet of steamers trading in the North Sea, the Baltic, the Mediterranean and the Black Sea. He also established iron and steel factories. During the World War he commanded a large share of the industrial work required by the German authorities, and rapidly increased his shipping interests. In 1920 he entered the Reichstag as a member of the German People's Party (the former National Liberal party). He began to buy up newspapers, whose democratic opinions were quickly modified in accordance with his own. In 1921 he was reported to be contemplating the formation of a super-trust to control the whole of German industry. He died in Berlin April 10, 1924. After his death the business, conducted by his son, rapidly shrank. In June 1925 a conference of bankers was called to investigate the financial affairs of the trust; and bit by bit the great organization was liquidated and sold. In Oct. 1925 a new company was registered at Hamburg under the title of Hugo Stinnes Coal Trade and Shipping Co., Ltd., the Stinnes family retaining 40% of the shares.

STIPPLE AND CRAYON ENGRAVING. Stipple-engraving was a little art of prettiness and daintiness, particularly well adapted to the translation of anecdotic pictures of a sentimental, mildly romantic, or domestic character, such as were

ENGLISH STIPPLE ENGRAVINGS OF THE 18TH CENTURY

Stipple engraving consists of a design drawn in a series or group of dots through an etching ground on a copper plate, and bitten with acid, then completed with dots made directly in the copper by a curved stipple-graver and perhaps a toothed wheel called a roulette

1. "Countess Spencer," engraved by Francesco Bartolozzi (1727–1813) after the painting by Sir Joshua Reynolds (1723–92). 2. "Dressing for the Masquerade," engraved by John Raphael Smith (1752–1812) after the painting by George Morland (1763–1804). 3. "Constancy," engraved by William Ward (1766–1826) after the painting by George Morland. 4. "Emma," engraved by John Jones (1745–97) after the painting by George Romney (1734–1802)

turned out in great numbers to supply a vogue in the English market during the reign of George III., many of which, popular in their day, survive only in the colour-prints and, though rarely of much artistic value, are yet now highly valued for their merit in survival. Nevertheless there were in the brief hey-day of the art a few among the multitude of designers and engravers who, realizing its limitations, made the most of its qualities, and these, such as J. R. Smith, William Ward and John Jones, the great mezzotinters Charles Wilkin, Thomas Burke, and whenever he chose to do so, Francesco Bartolozzi, with Peltro William Tomkins, Knight, Cheeseman, Schiavonetti, and others of the school, used the medium with individuality, undeniable charm and some artistic effect.

As a separate method, stipple-engraving came to England from France probably about 1764, by way of the crayon manner and the pastel, and these had evolved originally from the dotted manner, to which Ludvig von Siegen refers, in announcing the wonders of his own invention of mezzotint in 1642, as one of the modes of engraving which it was not. The dotted manner, a process of punching the plate with awl and mallet, called *opus mallei,* was used for its own sake with pictorial effect by Jan Lutma, an Amsterdam goldsmith, and the son of Rembrandt's sitter; but graven dots had been used earlier as accessory to line-engraving by Giulio Campagnola, Ottavio Leoni, and others, while in England the earliest important engraver of portraits, William Rogers, in Queen Elizabeth's reign, had stippled the face of the Queen, while Lucas Vorsterman used dots also to suggest the flesh in his head of Charles I.

But in the 18th century, when the crayon and pastel drawings of Boucher and others were popular in France, the aim of the engravers was to reproduce their texture on the copper-plate. The idea was in the air, so to speak, and several were engaged in the attempt to materialize it. Thus the invention of the crayon manner was claimed separately by Jean Charles François, Gilles Demarteau, who used his own version of it with artistic feeling, and Louis Marin Bonnet, an ingenious engraver to whom we owe at least the "pastel manner." This was a subtle development of the crayon mode admitting colour variety from a series of plates, as we may see in Bonnet's really fine print, *La Tête de Flore,* after Boucher, but François seems to have been actually the first in the field. The means used to imitate crayon drawing resembled soft-ground etching, though to produce the appearance of the chalk lines the etching-ground was perforated by tools of the roulette order, and various kinds of needles, while, after the usual biting by the acid, the finishing touches were given by graver, dry-point and roulette, though one often fancies the methods of soft-ground had been employed. François taught this crayon engraving, and with it the application of colour in printing *à la poupée,* to William Wynn Ryland, a young English line-engraver, who had been studying with Le Bas in Paris, and who, when funds were lacking after his return to London, bethought him of the new manner of engraving he had learnt. Then having called Bartolozzi into collaboration, they both modified and developed it as stipple-engraving.

The new method proved very easy of accomplishment, simple and rapid. The outline was etched in a series of dots, and all the shadows were put in with large or closer dots, or tiny groups of dots. When all the biting was over, the ground was removed, and the finishing was done with dry-point and stipple-graver, a curved tool. Then the printing was done with black, red, or several coloured inks, a rag-stump, or *poupée*, being used, and the plate freshly cleaned for each impression. Beginning by translating the pretty pseudo-classical designs of Angelica Kauffman and Cipriani, which acquired a very popular vogue, Ryland and Bartolozzi found the new method exceedingly profitable. To the ready hand of Bartolozzi it came almost as a fairy gift, with the facilities of the medium linking themselves to his sweet caressing sense of beauty. Indeed, he developed it with richer character in its fine shades than the unfortunate Ryland could do, as we may see in many notable prints after Reynolds and other distinguished painters. All the painters of the day were anxious to share in the profits so readily made by the stipple-prints which were filling the print-sellers' windows, and few native engravers could resist the easy attraction of the new method, while it brought also Italian and French engravers to learn it, and work here for the English market. There was also, up to the war with revolutionary France in 1793, a great trade in English prints on the continent, and Bonnet and other French engravers, adopting the stipple method, tried to get a share in this trade by issuing prints with titles often in misspelt English. Sir Robert Strange, the eminent line-engraver, launched an indignant tirade against stipple, and even denied its claim to be regarded as engraving at all, though there was no denying its efficacy as a medium for colour-printing, the white of the paper, showing between the tinted dots, affording a peculiarly luminous quality, and thus giving it a superiority over the coloured mezzotint, though it must be admitted that rarely was the stipple or the mezzotint of old time completely printed in colours, some portions invariably being left to be coloured by hand. Nevertheless, the popularity of stipple continued as long as the special subjects for which it was used remained in fashion, and as long as the leading 18th century painters and engravers survived the period of their comparatively short though successful collaboration, but it really waned with the advent of colour-lithography. Stipple-engraving is rarely practised nowadays as a separate art though a recent attempt has been made to revive it for origi expression by Dorothy Woollard. As a medium for original co printing it has completely given place to aquatint, wood wood engraving, lithography, or relief-etching from severa

STIRES, ERNEST MILMORE (1866– Long Island, was born in Norfolk, Va., on May 2 ceived the degree of B. Litt. at the University 1888, and from 1889–91 continued his studies a Theological seminary of Virginia, receiving the at Trinity college in 1901. The degree of LL.D. upon him at Kenyon college in 1903. He receive pointment as rector at West Point in 1891, and in the Church of the Good Shepherd in Augusta, Ga. year he was called to Grace church, Chicago, where until 1901. He then accepted a call to St. Thomas's ch York. Under his pastorate the parish became one of t important in the country. He was consecrated bishop of Island on Nov. 24, 1925.

STIRLING, WILLIAM ALEXANDER, Earl of (1567–1640), Scottish poet and statesman, generally known as William Alexander, was born at Menstrie House, near Stirling, about 1567, and probably educated at Stirling Grammar school: He may also have been to the universities of Glasgow and Leyden. He followed James VI. to England, where he became one of the gentlemen-extraordinary of Prince Henry's chamber. For the prince he wrote his *Paraenesis to the Prince* . . . (1604), a poem in eight-lined stanzas on the theme of princely duty. He was knighted in 1609; in 1614 he was appointed master of requests, and in July 1615 to a seat in the Scottish privy council. In 1613 he began a correspondence with Drummond of Hawthornden. In 1621 he received from James I. enormous grants of land in America, including Nova Scotia and New Brunswick, and was appointed lieutenant-governor of the new colony which, however, was ceded to the French in 1632. (*See* Nova Scotia: *History.*) From 1626 till his death he was the king's secretary for Scotland, and in 1630 was created viscount Stirling and Lord Alexander of Tullibody. In 1631 he edited and published a translation of the Psalms said to be by James I. In 1639 he became earl of Donovan. He died on Feb. 12, 1640, in London.

Alexander's poetical miscellanies and minor verse include *Aurora,* containing the first fancies of the author's youth (1604); *An Elegie on the Death of Prince Henrie,* and shorter pieces. He also wrote four tragedies, *Darius* (1603); *Croesus* (1604); *The Alexandrean* (1605), and *Julius Caesar* (1607); the first two of which were published together in 1604 as the *Monarchicke Tragedies;* they are didactic poems or dialogues rather than plays,

but they contain some fine soliloquies. Of Alexander's heroic poem *Jonathan* only the first book was written. *Domesday,* or *The Great Day of the Lord's Judgment* (1614) is a dreary production, in 12 books or "hours," in eight-lined stanzas. A collected edition of his work appeared in 1637, with the title *Recreations with the Muses* (folio), but did not include *Aurora* and the *Elegie.* A complete modern reprint *The Poetical Works,* etc., was published in 3 vols. (Glasgow, 1870).

His *Encouragement to Colonies* was edited for the Bannatyne Club by David Laing (1867), and by Edmund F. Slafter, in *Sir W. Alexander and Amer. Colonization* (Prince Society, Boston, Mass., 1865). *See* also E. F. Slafter, *The Copper Coinage of the Earl of Stirling, 1632* (1874); *The Earl of Stirling's Register of Royal Letters relative to the Affairs of Scotland and Nova Scotia from 1615–1635* (edit. C. Rogers, with biographical introduction 1884–85); C. Rogers, *Memorials of the Earl of Stirling* (1877), the introduction to the *Works* (1870) referred to above; the *Register of the Privy Council of Scotland, passim;* and the bibliography for William Drummond (*q.v.*) of Hawthornden.

STIRLING, WILLIAM ALEXANDER, titular EARL OF (1726–1783), American soldier, was born in New York city He served first as commissary and then as aide-de-camp to Governor William Shirley at the beginning of the French and Indian War, ...d in 1756 he accompanied Shirley to England, where he prose- ...d his claim to the earldom of Stirling In 1759 an Edinburgh ... declared him to be the nearest heir to the last earl of ..., and in 1761 he returned to America and assumed the title ... Stirling by which he was afterwards known in America. ...me a member of the New Jersey provincial council and ...neral of the colony In 1775 he sided with the patriot ...as appointed colonel of a regiment in New Jersey. ... became brigadier-general, and for a time was in ...ew York, and supervised the fortification of the ...ır. At the battle of Long Island he was taken ...is soon afterwards exchanged, and in Feb. 1777 ...-general. He participated in the battles of Tren- ... Brandywine and Germantown, and especially dis- ...iself at Monmouth. He took an active part in ex- ...onway Cabal, presided over the court-martial of ...les Lee, and enjoyed the confidence of Washington ...l degree. In Oct 1781 he took command of the ...partment at Albany to check an expected invasion from ...ie died at Albany on Jan 15, 1783. He was a member ...oard of governors of King's college (now Columbia uni- ...) and was devoted to the study of mathematics and ...nomy.

STIRLING, royal, municipal and police burgh, parish, river port and county town of Stirlingshire, Scotland Pop. (1921), 21,345. It is finely situated on the right bank of the Forth, 39½ m. N W. of Edinburgh and 29½ m N E of Glasgow, being served by the L.N.E and L.M.S. railways. The old town occupies the slopes of a basaltic hill (420 ft. above the sea) terminating on the north and west in a precipice. The modern quarters have been laid out on the level ground at the base, especially towards the south. Remains of a town wall exist at the south end of the Black walk. Formerly there were two main entrances—the South port and the "auld brig" over the Forth to the north, a high-pitched structure of four arches, now used only by foot-passengers. It dates from the end of the 14th century and was once literally "the key to the Highlands." Just below it is the bridge erected in 1829 from designs by Robert Stevenson, and below this again the railway viaduct The castle crowning the hill is of unknown age, but from the time that Alexander I died within its walls in 1124 till the union of the crowns in 1603 it was intimately associated with the fortunes of the Scottish monarchs. It is approached from the esplanade, on which stands a colossal statue of Robert Bruce. The main gateway, built by James III, gives access to the lower and then to the upper square, on the south side of which stands the palace, begun by James V. (1540) and completed by Mary of Guise. The east side of the quadrangle is occupied by the parliament house, a Gothic building of the time of James III., now used as a barrack-room and stores. On the north side of the square is the chapel royal, founded by Alexander I., rebuilt in the 15th century and again in 1594 by James VI. (who was christened in it), and afterwards converted into an armoury and finally a store-room. Below it is Gowan hill, and beyond this the Mote or Heading hill, on which Murdoch Stuart, 2nd duke of Albany, his two sons, and his father-in-law the earl of Lennox, were beheaded in 1425. In the plain to the south-west were the King's gardens, now under grass, with an octagonal turf-covered mound called the King's Knot in the centre. Farther south lies the King's park. On a hill of lower elevation than the castle and separated from the esplanade by a depression styled the Valley—the tilting-ground of former times—a cemetery has been laid out. Here is the Virgin Martyrs' Memorial, in memory of Margaret Maclachlan and Margaret Wilson, who were drowned by the rising tide in Wigtown bay for their fidelity to the Covenant (1685); the large pyramid to the memory of the Covenanters, and the Ladies' rock, from which ladies viewed the jousts in the Valley. Adjoining the cemetery on the south is the parish church, portions of which may have formed part of the first church, founded by David I. Since the Reformation it has been divided into two churches The choir (the East church) was added in 1494 by James IV, and the apse a few years later. At the west stands the stately battlemented square tower. The nave (the West church) is a transition between Romanesque and Gothic, with pointed windows. The crow-stepped Gothic gable of the south transept affords the main entrance to both churches. The choir is in the Decorated and Perpendicular styles. Within its walls Mary Queen of Scots was crowned in 1543, when nine months old, and in the same year the earl of Arran, regent of Scotland, abjured Protestantism; in 1544 an assembly of nobles appointed Mary of Guise queen-regent; on July 29, 1567, James VI. was crowned, John Knox preaching the sermon, and in Aug 1571 and June 1578 the general assembly of the Church of Scotland met. James Guthrie (1612–1661), the martyr, and Ebenezer Erskine (1680–1794), founder of the Scottish Secession Church, were two of the most distinguished ministers To the south-west of the church is Cowane's Hospital, founded in 1639 by John Cowane, dean of gild, and now used as a gildhall. Adjoining it is the military prison. Near the principal entrance to the esplanade stands Argyll's Lodging, erected about 1630 by the 1st earl of Stirling. On his death in 1640 it passed to the 1st marquess of Argyll and is now a military hospital. Broad street contains Mar's Work, the palace built by John Erskine, 1st (or 6th) earl of Mar, about 1570, according to tradition, out of the stones of Cambuskenneth Abbey; the old town house, erected in 1701 to replace that in which John Hamilton, the last Roman Catholic archbishop of St Andrews, was hanged for alleged complicity in the murders of Darnley and the regent Moray; the town cross, restored in 1891, and the house which was, as a mural tablet says, the "nursery of James VI. and his son Prince Henry." The Smith institute, founded in 1873 by Thomas Stewart Smith, an artist, contains a picture-gallery, museum and reading-room. Woollen spinning and manufactures are the staple industry, and iron-founding, carriage-building and agricultural implement-making are also carried on, in addition to furniture factories, cooperage and rubber works. There is some shipping from the small harbour, which is accessible only at high water.

Stirling is under the jurisdiction of a council with provost and bailies, and, with Falkirk and Grangemouth, returns a member to Parliament The Abbey Craig, an outlying spur of the Ochils, 1½ m north-east of Stirling, is a thickly-wooded hill on the top of which stands the Wallace monument (1869), a baronial tower, with a valhalla containing busts of eminent Scotsmen. Cambuskenneth abbey, on the left bank of the Forth, about 1 m. E N.E. of Stirling, was founded by David I. in 1147 for monks of the order of St. Augustine. Several Scots parliaments met within its walls. At the Reformation Mary Queen of Scots bestowed it on the 1st earl of Mar (1562), who is said to have used the stones for his palace in Stirling. All that remains of the abbey is the massive, four-storeyed tower, the west doorway and the foundations of some of the walls. The bones of James III. and his

queen, Margaret of Denmark, who were buried within the precincts, were discovered in 1864 and re-interred next year under a tomb at the high altar.

Stirling was known also as Snowdoun, which became the official title of the Scots heralds. The Romans probably had a station here. In 1119 it was a royal burgh and under Alexander I. was one of the Court of Four Burghs (superseded under James III. by the Convention of Royal Burghs). In 1174 it was handed over to the English in security for the treaty of Falaise, being restored to the Scots by Richard I. The earliest known charter was that granted in 1226 by Alexander II., who made the castle a royal residence. The fortress was repeatedly besieged during the wars of the Scottish Independence. In 1304 it fell with the town to Edward I. The English held it for ten years, and it was in order to raise the Scottish siege in 1314 that Edward II. risked the battle at Bannockburn. Edward Baliol surrendered it in 1334 in terms of his compact with Edward III., but the Scots regained it in 1339.

From this time till the collapse of Queen Mary's fortunes in 1568, Stirling almost shared with Edinburgh the rank and privileges of capital of the kingdom. It was the birthplace of James II. in 1430 and probably of James III. and James IV. In 1571 an attempt was made to surprise the castle by Mary's adherents, the regent Lennox being slain in the fray, and seven years later it was captured by James Douglas, 4th earl of Morton, after which a reconciliation took place between the Protestants and Roman Catholics. It was occupied in 1584 by the earls of Angus and Mar, the Protestant leaders, who, however, fled to England on the approach of the king. Next year they returned with a strong force and compelled James VI. to open the gates, his personal safety having been guaranteed. In 1594 Prince Henry was baptized in the chapel royal, which had been rebuilt on a larger scale. After the union of the crowns (1603) Stirling ceased to play a prominent part on the national stage. The privy council and court of session met in the town in 1637 on account of the disturbed state of Edinburgh. In 1641 Charles I. gave it its last governing charter, and four years afterwards parliament was held in Stirling on account of the plague in the capital, but the outbreak of the pest in Stirling caused the legislators to remove to Perth. During the Civil War the Covenanters held the town, to which the committees of church and state adjourned after Cromwell's victory at Dunbar (1650), but in August next year the castle was taken by General Monk. In 1715 the 3rd duke of Argyll held it to prevent the passage of the Forth by the Jacobites, and in 1746 it was ineffectually besieged by Prince Charles Edward.

STIRLING NUMBERS, in mathematics. In the year 1730 James Stirling, in his *Methodus Differentialis* introduced into analysis two sets of numbers which, because of their uses in various branches of analysis, their properties, and the methods used in their computation, have continued to attract the attention of mathematicians.

One of the latest writers on the subject, Professor Nielsen of Copenhagen has named them "Stirling numbers of the first and second kind" in honour of their discoverer.

Definitions.—The Stirling numbers of order n of the first kind may be defined as the co-efficients in the expansion of

$$(1+x)(1+2x)\cdots(1+nx)=1+{}_nS_1x+{}_nS_2x^2+{}_nS_3x^3+\cdots$$

in ascending powers of x, while the Stirling numbers of the second kind are found in

$$\frac{1}{(1+x)(1+2x)\cdots(1+nx)}=1-{}_nT_1x+{}_nT_2x^2-{}_nT_3x^3+\cdots,$$

also in ascending powers of x.

This definition immediately leads to the following theorems:

(a) The P^{th} Stirling number of order n of the first kind is equal to the sum of the products of the first n integers taken P at a time without repetition.

(b) The P^{th} Stirling number of the second kind of order n is equal to the sum of the products of the first n integers taken P at a time with repetitions.

Stirling used the numbers now named after him as a tool for expressing X^n as a series of factorials.

$$\begin{aligned}
x^2&=x(x-1)+x,\\
x^3&=x(x-1)(x-2)+3x(x-1)+x,\\
x^4&=x(x-1)(x-2)(x-3)+6x(x-1)(x-2)+7x(x-1)+x,\\
x^5&=x(x-1)(x-2)(x-3)(x-4)+10x(x-1)(x-2)(x-3)\text{-}\\
&\qquad+25x(x-1)(x-2)+15x(x-1)+x.
\end{aligned}$$

The coefficients of the various factorials (1·1; 1·3·1; 1·6·7·1; 1·10·25·15·1) are the Stirling numbers of the second kind. For about 150 years mathematicians considered it important to be able to express algebraic expressions in form of sequences of factorials. The result was a rich literature consisting of memoirs dealing with the peculiarities of this method of expression. In the year 1846 Weierstrass proved the general futility of this mode of notation, and since then the subject of "factorial notation" has slowly but surely been eliminated as a topic of discussion in mathematical literature. At present it is used only in certain problems of finite summation, in theories of interpolation, and as an example illustrating some of the uses of the Stirling numbers.

Applications.—George Boole in his treatise on the calculus of finite differences calls attention to the "system of numbers expressed by $\Delta^n\, O^m$ (differences of nothing)" without indicating whether he realized that these numbers were already used by Stirling. The formula given by Boole for $\Delta^n\, O^m$ may well be used for the calculation of the above mentioned coefficients T; *i.e.*, the Stirling numbers of the second kind,

$$\frac{1}{n!}\,{}_nT_{m-n}=n^m-\binom{n}{1}(n-1)^m+\binom{n}{2}(n-2)^m-\binom{n}{3}(n-3)^m+\cdots$$

The Stirling numbers of the second kind (T) also appear in the expansion of $(e^x-1)^p$. Thus,

$$\begin{aligned}
\frac{1}{2!}(e^x-1)^2&=\frac{x^2}{2!}+\frac{{}_2T_1x^3}{3!}+\frac{{}_2T_2x^4}{4!}+\cdots\\
\frac{1}{3!}(e^x-1)^3&=\frac{x^3}{3!}+\frac{{}_3T_1}{4!}x^4+\frac{{}_3T_2x^5}{5!}+\cdots\\
\frac{1}{p!}(e^x-1)^p&=\frac{x^p}{p!}+\frac{{}_pT_1}{(p+1)!}x^{p+1}+\frac{{}_pT_2}{(p+2)!}x^{p+2}+\cdots
\end{aligned}$$

Formulas.—Of the recurring formulas the most important are

$$\begin{aligned}
{}_{n+1}S_p&={}_nS_p+n\cdot{}_nS_{p-1},\\
{}_{n+1}T_p&={}_nT_p+n\cdot{}_{n+1}T_{p-1}.
\end{aligned}$$

Of the independent formulas developed by various writers, none is suitable for practical purposes; but theoretically the following formulas which appear in a work by Ettinghausen (1826) are important:

$${}_nS_p=\Sigma\frac{(n+1).}{a!\,b!\,c!\cdots1^a\,2^b\,3^c\cdots}$$

for all integral values of a,b,c . . . satisfying the equations:

$$\begin{aligned}
a+b+c+\cdots&=p+1,\\
a+2b+3c+\cdots&=n+1,
\end{aligned}$$

and

$${}_nT_p=\Sigma\frac{(n+p)!}{a!b!c!\cdots1^a(2!)^b(3!)^c\cdots}$$

for all integers satisfying the equations

$$\begin{aligned}
a+b+c+\cdots&=p,\\
a+2b+3c+\cdots&=n+p.
\end{aligned}$$

Relations between the S's and the T's are given by

$${}_nT_p=\begin{vmatrix}{}_nS_1 & 1 & \cdots & 0\\ {}_nS_2 & {}_nS_1 & \cdots & 0\\ \cdot & \cdot & \cdots & \cdot\\ \cdot & \cdot & \cdots & 1\\ {}_nS_p & {}_nS_{p-1} & \cdots & {}_nS_1\end{vmatrix},\ \text{and}\ {}_nS_p=\begin{vmatrix}{}_nT_1 & 1 & \cdots & 0\\ {}_nT_2 & {}_nT_1 & \cdots & 0\\ \cdot & \cdot & \cdots & 0\\ \cdot & \cdot & \cdots & 1\\ {}_nT_p & {}_nT_{p-1} & \cdots & {}_nT_1\end{vmatrix}.$$

The second formula is evidently obtained from the first by interchanging the *T's* and the *S's*

It has also been observed (*Amer. Math. Monthly*, 1928) that the Stirling numbers of the first kind can be obtained by performing the algebraic divisions,

$$\frac{2+x}{(1-x)^5}, \frac{6+8x+x^2}{(1-x)^7}, \frac{24+58x+22x^2+x^3}{(1-x)^9} \ldots$$

while the Stirling numbers of the second kind appear in the quotients of

$$\frac{1+2x}{(1-x)^5}, \frac{1+8x+6x^2}{(1-x)^7}, \frac{1+22x+58x^2+24x^3}{(1-x)^9} \ldots$$

The Stirling numbers have many important relationships to the Bernoulli numbers (*q.v.*), Euler numbers (*q.v*), and the tangential coefficients, and there are numerous formulas connecting them. In fact, there is a way of regarding the Bernoulli numbers as a species of Stirling numbers; that is $(e^x-1)^n$ always gives, when expanded, Stirling numbers, and when we let $n = -1$, we obtain a well-known expansion giving the Bernoulli numbers.

The consideration of $(e^x-1)^{-n}$ leads to what may be called ultra-Stirling numbers, a subject which, like the ultra-Bernoulli and ultra-Euler numbers has been very little studied.

STIRLINGSHIRE, midland county, Scotland, bounded north by Perthshire, north-east by Clackmannanshire and the Firth of Forth, south-east by Linlithgowshire, south by Lanarkshire and the detached part of Dumbartonshire and south-west and west by Dumbartonshire; area 288,842 ac. (excluding water). In the north-west the Grampians culminate in Ben Lomond (3,192 ft.), and the centre is occupied by the Lennox hills. The oldest rocks are the Dalradian schists in the north-west beyond a great fault which runs from near the bottom end of Loch Lomond in a north-easterly direction across Scotland. On the south-eastern side of the fault are the conglomerates and sandstones of Lower Old Red Sandstone age, followed by the Upper Old Red series. Then follows the Carboniferous system occupying the rest of the county The true coal-measures are well-developed between Grangemouth and Stenhousemuir and about Falkirk. Intrusive sheets of basalt have penetrated the Carboniferous rocks and are quarried for road metal; Abbey Craig and Stirling Castle hill are formed of one of the more important of these intrusions Much boulder clay covers the older rocks and an interesting blue marine clay is found beneath it in the Endrick valley. The Carse of Stirling is overlaid by the muds and sands of the 50-ft. raised beach; and traces of the 100-ft. beach also are found

The chief river is the Forth, which forms most of the northern boundary. The other important streams are the Carron, rising in Campsie fells and flowing to the Forth at Grangemouth; the Endrick, which, rising in Fintry hills, empties itself into Loch Lomond, the Kelvin, which, from its source in Kilsyth hills, flows southwest to the Clyde at Glasgow after a run of 22 m; and the Avon, rising in the detached portion of Dumbartonshire, and flowing to the Forth. The principal lochs include the greater part of the eastern waters of Loch Lomond; a small portion of the upper end of Loch Katrine, and Loch Arklet, in the north-west area, which, like Loch Katrine, provides part of the water supply of Glasgow. The Forth and Clyde canal crosses the south-eastern corner of the county from Grangemouth to Castlecary.

History and Antiquities.—The wall of Antonius, built by Lollius Urbicus, in A D. 142, connecting the Forth and Clyde, passed through the south-east of the county, in which it is locally known as Graham's Dyke. At Castlecary and Camelon many relics have been found. The Camelon causeway ran eastwards from Castlecary and crossed the rampart at Camelon, whence it proceeded northwards to Stirling and the Forth, where there was a station near the present bridge of Drip. Thence it crossed the river to Keir and Dunblane in Perthshire. After the withdrawal of the Romans the county once more fell into the hands of the native inhabitants, who, however, gradually retired before the advance of the Saxons and Scots. By the time of Malcolm Canmore (d. 1093) the lowland area had become settled, but the highland tract remained a disturbed and disturbing region until the pacification following the Jacobite rising of 1745–6. The county played a conspicuous part in the struggle for Scottish independence, being particularly associated with many of the exploits of Sir William Wallace and Robert Bruce. The three great battles of the independence were fought in the shire—Stirling Bridge (1297), Falkirk (1298), Bannockburn (1314). James III was stabbed to death in a cottage in the village of Milton after the battle of Sauchieburn (1488), but apart from the disastrous defeat of the Covenanters at Kilsyth (1645) and the transitory triumph which Prince Charles Edward won at Falkirk (1746), the history of the shire practically centres in that of the county town

. **Agriculture and Industries.**—The arable soils are of two kinds, locally distinguished as "carse" and "dryfield," the rest of the land being composed of pasture, moor and peat The "carse" extends along the valley from Buchlyvie to the eastern boundary. The soil consists of the finest clays, without stones, but interspersed with strata of marine shells It has been largely stripped of the overlying peat, and by draining, subsoil ploughing and the use of lime has been converted into a rich soil, especially adapted for wheat and beans. The "dryfield," which occupies the valleys and the higher ground bordering the carse, is fertile and suited for potatoes and turnips. Oats and wheat are the chief grain crops Beans are also extensively grown The cattle are comparatively few, but numbers of sheep, chiefly black-faced, are raised The average size of the holdings is from 70 to 80 acres. Birches grow on the lower slopes of the mountains in Buchanan and Drymen, and oaks on the banks of Loch Lomond Larch and Scots fir are the leading trees in modern plantations.

The coalfield of the south-east supplies the staple industry, and coal is also mined in the east, near the Forth and Clyde canal Iron ore and fireclay are also obtained, while granite, limestone and sandstone are quarried. The ironworks at Carron near Falkirk are important and nails are made at St Ninians and elsewhere. Woollens are manufactured at Stirling and Bannockburn; calico-printing and bleaching are established in the south-west, especially at Lennoxtown and Milton, and there are chemical works at Falkirk and Denny. Tanning, iron-founding, paper-making, brewing and distilling are carried on at different places, and shipbuilding at Grangemouth, the chief port. The southern and south-eastern districts are served by the L N E. railway from Edinburgh to Glasgow (via Falkirk) and the L M.S railway from Glasgow to Stirling (via Larbert), while branches connect Grangemouth, Denny and other places with the through-lines. A L N E line crosses the shire, mostly in the north, from Stirling to Balloch, and there is a line of the same company from Glasgow to Aberfoyle.

Population and Administration.—In 1921 the population was 161,719. The principal towns are Falkirk (pop 33,308), Stirling (21,345), Grangemouth (9,723), Kilsyth (7,600), Stenhousemuir (4,601), Denny and Dunipace (5,130), Bridge of Allan (3,579), and Bonnybridge (3,168). The shire returns a member to parliament with Clackmannan, and Stirling, Falkirk and Grangemouth one member. The police burghs include Falkirk, Grangemouth, Kilsyth, Denny and Dunipace and Bridge of Allan. The shire forms a sheriffdom with the counties of Dumbarton and Clackmannan, but there is a resident sheriff-substitute at Stirling and another at Falkirk The shire is under school board jurisdiction, and there are high schools at Stirling and Falkirk

STJERNHJELM, GEORG (1598–1672), Swedish poet and scholar, whose original name was Göran Lilja, was born at Wika in Dalecarlia on Aug 7, 1598. He took his degree at Greifswald, and spent some years in travelling over every quarter of Europe. Gustavus Adolphus gave him a responsible post at Dorpat in 1630, and raised him next year to the nobility. After the king's death, Christina attached him, as a kind of poet laureate, to her

court in Stockholm. His property lay in Livonia, and when the Russians plundered that Province in 1656 the poet, who was in temporary disgrace at the court, was reduced to extreme poverty for two or three years. He subsequently became judge at Trondhjem, member of the council of war (1661) and president (1667) of the College of Antiquities at Stockholm. He died at Stockholm on April 22, 1672. His greatest poem *Hercules* (pr. 1653) is a didactic allegory in hexameters, written in very musical verse, and with almost Oriental splendour of phrase and imagery. *Bröllops-Besvärs Ihugkommelse,* a sort of serio-comic epithalamium in the same measure, is another brilliant work. His masques, *Then fångne Cupido* (Cupid Caught) (1649), *Freds-afl* (The Birth of Peace) (1649), and *Parnassus triumphans* (1651), were written for the entertainment of Queen Christina. He can scarcely be said to have been successful in his attempt, in the first two of these, to introduce unrhymed song-measures.

Stjernhjelm was an active philologist, and left a great number of works on language, of which only a few have been printed. He also wrote on history, mathematics, philosophy and natural science, producing original and valuable work on every subject he attempted. There is a full list of his writings in the *Svenskt biographiskt Lexikon,* vol. xv. (Uppsala, 1848).

STOA, a public building of ancient Greece, whose roof is supported by one or more rows of columns, usually placed adjacent to the agora (*q.v.*), and used either for a sheltered promenade or as a market hall. Extensive remains of stoae exist at Assus. At Athens, there are remains of the stoa of Attalus II. (159–138 B.C.); the so-called stoa of Hadrian is, in reality, a part of the great library of Hadrian.

STOBAEUS, JOANNES, so called from his native place Stobi in Macedonia, the compiler of a valuable series of extracts from Greek authors. Of his life nothing is known, but he probably belongs to the latter half of the 5th century A.D. From his silence in regard to Christian authors, it is inferred that he was not a Christian.

The extracts were intended by Stobaeus for his son Septimius, and were preceded by a letter briefly explaining the purpose of the work and giving a summary of the contents. From this summary (preserved in Photius's *Bibliotheca*) we learn that Stobaeus divided his work into four books and two volumes. In most of our MSS. the work is divided into three books, of which the first and second are generally called Ἐκλογαὶ φυσικαὶ καὶ ἠθικαί (Physical and Moral Extracts), and the third Ἀνθολόγιον (*Florilegium* or *Sermones*). The differences in arrangement between the work as we have it and the summary in Photius, combined with its fragmentary nature in places, suggests that what we have is a later Byzantine epitome. The first book teaches physics—in the wide Greek sense—by means of extracts. It is often untrustworthy: Stobaeus betrays a tendency to confound the dogmas of the early Ionic philosophers, and he occasionally mixes up Platonism with Pythagoreanism. The third and fourth books, like the larger part of the second, treat of ethics and politics. In all, Stobaeus quotes more than five hundred writers.

Editio princeps (1609); *Eclogae,* ed. T. Gaisford (1822), A. Meineke (1860–64); *Florilegium,* ed. T. Gaisford (1850), A. Meineke (1855–1857), C. Wachsmuth and O. Hense (1884–94, and 1909).

STOCK. When money is invested, the investor requires some tangible evidence of his investment and some measure of its size. Moreover, when, as is usually the case, he is one of many investors in the same object, means must exist of defining rigidly and legally the proportion held by each. This is true whether he invests his capital in a loan to a government, municipality or trading concern, or acquires a definite share of the last-named.

This evidence of the existence, nature and size of his holding consists either of "stock" or of "shares." Stock in Great Britain can be issued, bought, sold or redeemed in any odd amount. A share is indivisible and represents, as its name implies, a definite proportion of the total nominal value of the property. This is the vital distinction, which is best clarified by an example.

Stock is always expressed in "so many pounds, shillings and pence face value." Thus "£200 consols" means "£200 face value of British Consolidated Stock." The face value, in conjunction with the rate of interest, determines the dividend. Thus the rate of interest upon consols is 2½ per cent., and so the dividend upon £200 consols is £5 per annum. Face value has no connection with the market value. Thus a sale of £200 consols may fetch no more than £100 in cash. Market value depends simply upon the current price, which is usually quoted in pounds cash per £100 stock. Thus, at a market price of 60, £200 consols could be bought and sold for £120 cash. Stock is always bought and sold in quantities expressed in face value, viz.: a sale of £215.6.8 stock, or a purchase of £350.10.4 stock. Shares are always bought and sold by number, viz.: 352 Courtaulds ordinary shares. (*See* SHARES.)

The chief forms of stock are as follows—(*A*) Government (British, colonial or foreign), municipal (British, colonial or foreign) and debenture stock (railways, shipping, trading, manufacturing, etc.). In every case the stock is evidence of a loan made to the Government, municipality, railway, etc. The stock may be redeemable or it may be irredeemable. The total amount issued is usually limited, but the borrower may have power to issue more at his discretion. It may be issued at par (*i.e.,* £100 stock for £100 cash) or at a premium or a discount, *i.e.,* at more or less than £100 cash. It may be redeemable at par or at a premium. It may have definite, tangible security behind it, such as a lien on the customs revenues or upon the manufacturer's plant, or it may be secured simply by the word of the borrower. The vital point is that it is measured in, bought and sold according to, and its dividends based upon, its face value.

(*B*) Preferred, ordinary and deferred stock. Such stock is evidence of a definite share in the property owned by the issuing company—of which each stockholder is *ipso facto* a member. By virtue of his holding, he is entitled to a share of the net profits, after interest on debentures has been met, and to certain rights, privileges and liabilities, according to his class of holding. His stock comes under the broad heading of capital stock. As a rule, capital is issued in the form of shares and not stock, and so the reader is referred to the article on SHARES for any further description. Two points only need here be mentioned. The first is that dividends are always declared in the form of "so much per cent. on the face value of the stock." The second is that, in case of liquidation, any available assets are divided among the stockholders, class by class, in the same proportion as that borne by the face value of their holding to the total face value of the whole of the outstanding stock in the class to which they belong.

For forms of issue, *see* TRANSFER. (N. E. C.)

UNITED STATES

The usage of the terms "stocks" and "shares" in the United States is quite different from that in England. In the United States stock signifies the ownership in the business held by the many persons who have bought interest in it and who are known as the stockholders. It does not carry the idea of a loan but indicates always an actual purchase of part ownership. Loans to either private businesses, governments or municipalities are represented by "bonds," except in the case of New York city, which still adheres to the English usage and still has outstanding its "stock," which is to all intents and purposes equivalent to the municipal bonds of other American cities. The aggregate ownership or stock of an American corporation is divided into a large number of units or shares, of which each stockholder may hold one or many. The share, then, is one of the units of ownership. This ownership is represented by "certificates of stock," and when a person buys one or more shares of stock he receives as evidence of this ownership a certificate of stock filled in for the proper number of shares. This is a convenient and practical method of representing ownership, because the ownership can readily be transferred by the transfer of the certificate. (*See* TRANSFER.) Owners of stock in a corporation participate in the prosperity of the company by receiving their proportionate share of any profits that the board of directors sees fit from time to time to divide among them. This division of surplus is generally made annually, semi-

annually or quarterly, and all moneys or other property so divided among the shareholders is called a dividend

CLASSES OF STOCK

Stock of a corporation is a commodity which the corporation must sell in order to raise the funds necessary for the business, and therefore it is incumbent upon the corporation to make this commodity as attractive as possible, this in order not only that it may be disposed of easily but also at an advantageous price. Stocks are issued, therefore, in several classes providing numerous combinations of the three elements, income, control and risk. The average buyer of securities wants as large and as steady an income as possible with the smallest risk, and takes comparatively little interest in the control. The cautious investor will take a smaller income if there be less risk attached, whereas the speculatively inclined will take a greater risk for the chance of greater income. Instances often occur where control of the company is the chief end sought by the stock-buyer and he will practically ignore both present risk and income to get the control. The two great divisions or classifications of stock are "common" and "preferred."

Common Stock is simply ownership in the corporation, carrying with it all the usual rights of stockholders (unless otherwise specified) but no special privileges or preferences. These fundamental rights of stockholders are: (1) To proportionate ownership in the undivided assets of the corporation and to a certificate stating this ownership in shares. (2) To transfer ownership of his shares. (3) To receive dividends when earned and declared by the board of directors (4) To inspect the corporate books. (5) To subscribe, in proportion to his holdings, to any new issue of stock. (6) To proportionate control through voting power. (7) To vote on other questions affecting the corporation property as a whole. (8) To protect the corporation against wrongful acts of a majority. (9) To restrain *ultra vires* acts of the corporation (10) To share in the proceeds of dissolution

Preferred Stock is stock which, while it possesses the same rights and privileges as common stock (unless otherwise specified), has in addition certain more or less valuable and desirable preferences. It may be preferred as to assets, dividends or both, but in ordinary parlance the term "preferred stock" means preferred as to dividends

Being preferred as to assets means that in case of dissolution of the company, the holders of the stock will receive their portion of the proceeds of dissolution before holders of other stock not preferred as to assets will participate. This preference is, of course, of no service to the stockholder as long as his company is prosperous and in no danger of dissolution, but in the case of weak companies the preference tends to give his stock a higher market value than stock not so preferred. And in the case of actual dissolution where the assets are not sufficient to satisfy all, the preference will prove to be most valuable.

"Preferred as to dividends" means that this stock is entitled to a specified rate of dividend out of the earnings before any dividend is given to the stock not so preferred. It does not mean that a certain dividend is guaranteed but merely that if any amount of the earnings be declared as a dividend, the amount necessary to pay the specified rate of dividend on the preferred stock, or such part of such dividend as possible, must be used for this purpose before any is allocated to pay a dividend on non-preferred stock. If the entire amount declared as a dividend is absorbed by the dividend on the preferred stock, it means simply that the non-preferred or common stock gets nothing. In prosperous companies, however, it is usually possible to pay the stipulated rate to the preferred stock and still have sufficient moneys left to pay an equal or even larger rate to the common stock. It is ordinarily only fair that the common stock should get more in view of the fact that it takes a risk by permitting the preferred stock to take out its share of dividend first.

It is sometimes deemed advisable to have several issues of preferred stock, one taking procedure over the next, just as ordinary preferred takes precedence over common. These several issues are then usually classified as 1st preferred, 2nd preferred, 3rd preferred and so on, or sometimes as preferred A, preferred B, preferred C.

These two great classes of stock, common and preferred, have not by any means satisfied the wants of investors and speculators, and hence a large number of variations have grown up, particularly in preferred stock, affecting the income, control or risk of the stockholders in various manners The more important of these various classes will be explained

Non-Participating and Participating.—Non-participating preferred stock is stock which, through the terms of its issue and sale, is to receive a preferential dividend at a stipulated rate, usually about 6%, and nothing whatever beyond that, all other dividend, regardless of its amount, going to the common stock.

Participating preferred stock is that which is to receive first its preferential dividend at the stipulated rate and after that is to participate or share with the other stock in the remainder of the funds declared as dividend. This participation or sharing may be done in one of a number of ways, but regardless of the manner of participation, if the preferred stock shares in any way in the dividend over and above its stipulated rate, it is participating stock. The methods of participation are generally known as "participating simply," "participating immediately" and "participating specially."

Simple Participating.—Simple or ordinary participation is an arrangement whereby the preferred stock first gets its dividends up to the specified rate; after that the common stock will be paid dividends as far as possible up to and including the same rate that the preferred has received; if, after having paid both the preferred and the common the same rate of dividend, there be anything left of the total amount declared as dividend, it is shared or participated in by both the preferred and common alike, just as though they were only one class.

The term "preferred stock" in itself means that it is simply participating.

Participating Immediately.—Preferred stock is said to be immediately participating when the arrangement for apportioning the dividend among the classes of stock provides that the preferred stock first receives dividend up to the specified rate and that immediately thereafter without first giving the common stock a dividend payment at the same rate, all the remainder of the dividend money is allotted to all stock alike, regardless of whether it be preferred or common

Participating Specially.—The above described methods of participation are, however, by no means the only ones. As a matter of fact, the number of methods of participation is limited only by the ingenuity of the company organizers. It is possible, for instance, to have the preferred get 6%, then the common 6%, then the preferred all the remainder; or the preferred 6%, then common 6%, then preferred 4%, then common 2% and the remainder *pro rata;* or preferred 5%, then common 6%, then all the remainder to preferred and common in the proportion of two to one, or any other arrangement whatever that may be provided in the certificate of incorporation, which in this respect constitutes a contract between the company and the stockholder.

Non-cumulative and Cumulative—The dividends on preferred stock may be non-cumulative or cumulative. Provision is often made in the certificate of incorporation that if sufficient dividends are not declared in any one year to pay the full dividend on the preferred stock, there is no obligation on the part of the corporation to make up the deficiency in any subsequent year. This means that dividends or parts of dividends not paid to preferred stockholders in any given year are lost to them forever Stock governed by this provision is known as "non-cumulative."

Cumulative preferred stock, on the other hand, is stock, the stipulated dividend of which, if not paid in full in one or more years, carries over from year to year till fully paid. When dividends have not been declared, or have been declared in amount insufficient to pay the full specified rate of dividend on this cumulative preferred stock, they are in arrears and as long as they are unpaid they constitute a claim on future earnings prior to any dividend claim of the common stock. In other words, common stockholders are not entitled to receive any dividend as long

as the cumulative preferred stock dividends are in arrears. In case the certificate of incorporation makes no provision concerning whether or not the preferred stock dividend is to be cumulative, it has been held by the courts that the dividend shall be cumulative.

Companies sometimes provide that their preferred stock shall be non-cumulative for several years, after which it shall become cumulative. This provision relieves the company of the necessity of paying full dividends on the preferred stock during the early years when earnings are expected to be small or of having the dividend accumulate as a charge against future years, and yet assures the stock almost as good selling power as if it were fully cumulative from the first.

Redeemable Stock.—Preferred stock, or certain classes of preferred stock, are occasionally made redeemable. This means that the company has the option under the conditions and on terms specified in the certificate of incorporation, of redeeming or buying back the stork from the stockholders. This redemption right rests, of course, entirely with the company, and stockholders can neither compel nor refuse redemption of their stock. Some advance notice of intended redemption is usually provided for, and a redemption price is generally set at a premium so as to compensate the holder for the loss of his investment and give him an opportunity to seek a re-investment of his money without suffering loss of income in the interim. Redemption at a premium is not universal, however, many companies having the redemption price set at par. If the redeemable stock has the voting power, its redemption has considerable effect upon the control of the company because of the elimination of all the votes represented by it.

Redeemability also may have a material effect upon the market price of a stock, the tendency being to keep the market price lower than it otherwise might be. If the stock is redeemable at 110 and has an investment value of 140, a buyer would in all probability refuse to pay this much for it, fearing that the corporation might exercise its redemption privilege and deprive him of his stock at 110, thus bringing about a considerable loss. If, on the other hand, the investment value is below the redemption price, the redemption feature would ordinarily have no effect on the market unless to make the stock slightly less attractive because of the fact that there is an upper limit to the possible price rise.

Convertible Stock.—One or more classes of stock may be made convertible, that is, exchangeable at the option of the holder, into some other specified security. Conversion, unlike redemption, is always at the option of the holder. The certificate of incorporation may make certain stipulations or set a certain time limit for the conversion, but within these restrictions the stockholder can demand the conversion at his pleasure. The most usual conversion permitted is from preferred to common stock. Convertible stock of this type is quite popular because it enables the holder to receive preference as to dividends when the earnings are small and there is little left for the common dividends, and yet permits him to trade in his stock for common in case the earnings become large and the common is receiving large returns.

The matter of control also frequently enters, as non-voting preferred stock is often convertible into voting common stock. This feature will sometimes induce stockholders to convert, even at a financial loss. Occasionally, stock is issued which is convertible into bonds. This is rare, however, and is hedged about with various protective stipulations. In the first place, such conversion should be only at the option of the company, for if this were not the case, holders of such stock in a weak or insolvent company could convert their stock into bonds and thus share in the proceeds of dissolution ahead of many creditors and on an equal footing with other bondholders of the company who acquired them through *bona fide* purchase, which is manifestly unfair. The money which stockholders pay into the company for their ownership is a part of the owned capital of the company, and it is upon the strength of this owned capital and the security afforded by it that the company is enabled to obtain its borrowed capital through the sale of bonds. If, therefore, a large number of stockholders are permitted to convert their stock into bonds, thus becoming creditors of the company instead of part owners, it naturally means increase of bonded debt with no increase whatever of assets, and lessens the value of all other bonds.

Protected Preferred Stock.—Recently some companies have been making some of their preferred stock especially attractive as an investment by "protecting the dividend." This means simply that after the preferred dividend is paid, a certain amount is placed each year in a reserve or sinking fund, before the dividend is paid to the common stock. This sinking fund is built up to some required size and is to be used to pay the preferred dividends in case of poor years when the current surplus would not be sufficient. When this fund reaches the stipulated size, it is not built up further, but the dividends can then go direct to the common stock without the fund payment coming in ahead. If the fund is depleted, however, by being drawn on to meet a preferred dividend in a poor year, it must be built up to full requirements again as before.

Debenture Stock.—This term is very rarely used in the United States. It is an English expression meaning, in reality, not stock at all but a bond, corresponding to the American debenture bond. In American finance, however, the name has been adopted occasionally and applied to a special type of stock conferring rights, superior to both preferred and common, something in the nature of a prior preference stock. The best known example of this use of the term is the debenture stock of the General Motors Corporation.

Prior Preference Stock.—Prior preference stock, or prior lien stock, is a term rarely used but indicates usually that, after the issuance of the regular preferred stock, another issue has, with the consent of the old stockholders, been issued having a claim prior to that of all other stocks on dividends or assets. Upon issue, it becomes a first preferred stock and the other names serve merely as convenient descriptions. The prior preferred stock of the Goodyear Tire and Rubber Company and the preferred stock of the Market Street Railway Company of San Francisco are examples.

Guaranteed Stocks.—Guaranteed stock is stock whose dividend payments are guaranteed by some other company, usually one which is using the property of the issuing concern. Railway companies frequently lease and operate the property of other companies and, as part of the rental, guarantee the payment of dividends at a certain rate to all the stockholders. Although such operation is most general among railway companies, it is frequently practised among industrials also. Preferred stock is sometimes referred to as guaranteed stock, a term which, of course, is erroneous. A corporation cannot guarantee its own stock and cannot issue a guaranteed stock.

Voting and Non-voting Stock.—All stockholders have the inherent right to participate in the management of the corporation through voting for directors and on other matters. Non-voting stock may be issued, however, and purchasers of such stock voluntarily surrender their voting rights. It is generally customary to give the vote to the common stock and to withhold it from the preferred. The vote may be apportioned among several classes of stock in any desired manner as long as at least one class of stock is vested with voting power. If stock is issued as voting stock, however, such stock cannot be deprived of the vote without the consent of the holder.

Vetoing Stock.—Vetoing is the name given to stock which has not general voting power but is entitled through provision of the certificate of incorporation to vote on certain questions. Thus a certain issue of preferred stock may be voteless except on the question of the issue of additional preferred stock on which question it is given the voting right.

It is quite common to give to non-voting preferred stock the right to vote after its dividends have not been paid for a certain number of years and to continue this voting power as long as the dividends are unpaid, or in case of cumulative preferred stock as long as dividends are in arrears. In such cases this stock is sometimes given the right to vote along with the common, sometimes

the exclusive voting right, and sometimes the right to elect the majority of the board of directors.

Par Value and Non-par Value Stock.—For a great many years each share of stock of a corporation was given a nominal or par value, the common unit being a share with a par value of $100. The sum of all of the $100 shares constitutes the nominal value of all the authorized stock of the company. This par value, however, does not necessarily represent any real value, though many people are misled by it. A share of stock may have a par value of $100 while the book value may be $80 and its actual market value $60. The nominal or par valuation of stock is, therefore, purely artificial. It furnishes a basis or principal amount upon which to reckon dividends on a percentage basis, but otherwise is no indication of real value.

Since 1912 there has grown up the practice of issuing shares of stock without any nominal or par value, known variously as non-par value, or no-par value stock, stock without par value, and unvalued shares. The issuance of non-par value stock is now permitted by the law of 32 States, and the extent of its use may be judged by the fact that about 10% of all the charters filed in New York for the five years ending in 1928 contained provisions for the issuance of such stock. The statutes usually provide that such stock shall be sold by the company at a price not less than that prescribed in the certificate of incorporation, or the fair market value, or as may be from time to time set by the board of directors provided that the certificate of incorporation confers this authority, or for such consideration as shall be consented to or approved by the holders of the majority of shares at a meeting called to vote on the question. All non-par value shares sold in accordance with these legal provisions are deemed fully paid and non-assessable and the holder of such shares is not liable to the corporation or to the creditors in respect thereto. Every certificate of stock without par value must show the total number of such shares authorized, as well as the number represented by the certificate, and also the authorized number of par-value shares, if any, and their par value, thus making it possible to determine the proportionate interest in the net assets of a corporation which a given stock certificate represents. Having no par value or base on which to estimate a percentage dividend, the total dividend allotment is divided equally among all the non-par value shares outstanding, and declared as so many dollars per share. (J. H. B.)

STOCKBRIDGE, a town of Berkshire county, Massachusetts, U.S.A., on the Housatonic river, near the western boundary of the State; served by the New York, New Haven and Hartford railroad. Pop. (1925) 1,830 (State census). It is a summer and autumn resort, and a region of historic interest. Within its area of 24 sq m. are Lake Mahkeenac or Stockbridge Bowl, Ice Glen (where caverns are lined with ice even in midsummer), and Monument mountain (1,710 ft.). In 1736 a plantation 6 m. square (including the present town of Stockbridge) was laid out for the Mohican Indians who had come to the Housatonic valley from the west bank of the Hudson when white settlements began to encroach on their territory, and among whom John Sergeant had established a mission in 1734. In 1739 this "Indian Town" was incorporated as the town of Stockbridge. The Indians held their lands in severalty. They had a school and a church which was under the charge of Jonathan Edwards from 1750 to 1758. Many of them fought on the American side during the Revolution. In 1783–88 nearly all of them moved to New York, where they built New Stockbridge 14 m S. of the present site of Utica, and by 1829 most of them had gone to Wisconsin.

STOCKBROKER, an agent who deals in stocks and shares. He need not be a member of any recognized stock exchange, nor of an association of stock exchanges. He need not confine his energies to dealing in only such securities as those which are quoted in a stock exchange. The broker-member of the London stock exchange is an agent for the buying and the selling of stocks and shares of any description, and his status is kept strictly clear from that of a stockjobber, so far as the London stock exchange rules are concerned. The broker, if a stock exchange member, acts as an agent; seldom as a principal. He does not as a rule buy from a client nor sell to a client. He buys or sells on behalf of the client, and takes a certain amount of commission, the extent of which is laid down in stock exchange rules for members of the stock exchange as his remuneration for doing the business. He is not allowed, in the London stock exchange, to buy 100 shares from a client say at £5 and sell them simultaneously to another client at £5 5s. To do this would be acting as a principal, which is, according to the London stock exchange rules, the part assigned to a stockjobber.

The man who would become a broker in the London stock exchange usually finds that the best way of achieving his end is to obtain a seat in the office of a stock exchange firm, entering either as an office boy or a clerk, and gradually working his way through the various stages which stand between the outsider and the full-blown member of the stock exchange. He can become a member without delay, provided he is able to obtain three sureties who will guarantee, in the sum of £500 each, the fulfilment of his obligations for four years from the date of his admission. If the candidate has served as a clerk in the stock exchange for four years previously to the lodging of his application-form, two sureties, or recommenders, only are required, who must each enter into an obligation as above mentioned, but for £300 apiece. The scale of the London stock exchange charges, both for admission fee and annual subscription, is substantially less in the case of the experienced man. Every candidate for membership must obtain a nomination, the price of which varies considerably. When first created some years before the war, a nomination reached the value of £700. After the war, nominations became at one time practically valueless. Several are known to have changed hands at £5 apiece. After that an improvement set in, and the price rose above £1,000, but it varies very widely, according, on the one hand, to the demand that there happens to be for stock exchange membership, and on the other, the supply of nominations available by reason of the death or resignation of members.

Strict rules govern the stockbroker in the London stock exchange, and many of the provincial stock exchanges have modelled their rules upon them. He must be a British subject; he has to apply for re-election every year; he must state whether he intends to act as broker or jobber; he must not be a principal in any business other than that of the stock exchange, nor must he be a member of, or subscriber to, any other institution where dealings in stocks and shares are carried on. His wife, also, must not be engaged in business. His duties bring him into contact with members of the public, his clients, and with fellow-members of the stock exchange, brokers and jobbers alike, and he acts as agent between the public on the one side and members of the stock exchange on the other. He is required to have a general knowledge of all the markets in which he is called upon to deal, and he must be prepared to give reasonable answers to the hundreds of questions with which he is plied on all sorts of subjects. Drawing his business from members of the public, he is obliged to have offices, a staff of clerks, telephones, and all the paraphernalia connected with correspondence, being involved in heavier expenses on this account than the jobber, whose outgoings are on a more modest scale. The broker's life is more arduous than that of a jobber, involving longer hours and the exercise of unlimited patience, for he has to make allowance for the fact that the majority of his clients do not grasp the intimate details of what is after all a very technical business. He may, for instance, have a perfectly clear idea of what "cum dividend" and "ex dividend" imply, but it is not an easy matter to impart the same information to a country client who seldom deals in stock and shares. His first daily duty, after having digested the financial parts of his newspaper, is to deal with the correspondence that has reached him, and extract from it the orders that he will take into the stock exchange for execution when the markets open, as they do at about half-past ten, the official time being a quarter to eleven. There he buys or sells War Loan in one market, Kafirs in another, artificial silks in

another, going through various parts of the House that have no strict delimitations, one market impinging on the next. The men round the markets who deal in specialized stocks and shares are the jobbers, and to them the broker proceeds, knowing that he will be able to get a double price made to him, at the higher of which he can buy and at the lower of which he can sell without the jobber knowing in advance which of the two courses he intends to take in executing his client's order.

The outside broker is governed only by the laws of the land, whereas the member of the stock exchange is controlled by the rules laid down for the conduct of business in his own exchange. The outside broker is free to advertise (which the member of the stock exchange may not do), and is exempt from paying entrance fees or subscriptions. He can approach whom he likes with offers to buy or sell shares, acting as agent or principal as it suits him. Some outside firms specialize in somewhat unfamiliar stocks and shares, just as in the stock exchange itself there are broker firms who make a feature of one particular market, though they are ready to deal in anything else in which they get an order. The public is protected in dealing with members of recognized stock exchanges, for the committees of those exchanges exercise a stricter control over their members than does the law over outside firms. (W. L.)

United States.—A stockbroker is an agent who deals in stocks, bonds and other securities either on or off an organized exchange. Legally, the relationship between the broker and customer is not only that of agent and principal but becomes that of creditor and debtor and that of pledgee and pledgor when the customer purchases on margin and the broker furnishes the required additional funds secured by collateral. The relationships between brokers and their customers are governed by the various and differing State statutes, custom, business policy and the constitutions and rules of the organized exchanges. The New York Stock Exchange does not permit a corporation to become a member; consequently brokerage houses with membership on the exchange are partnerships.

The distinction between brokers and jobbers, which obtains in London, does not exist in the United States. On the New York Stock Exchange all brokers are free to trade with one another and with the public as they choose provided they conform with the constitution and rules of the exchange. Brokers on the New York Stock Exchange may be divided, according to the special nature of their business, into five groups: (1) commission brokers, those who act for the public at a commission fixed by the exchange; (2) "two-dollar" brokers, who act as agents for other member brokers on the exchange at a rate of $2.50 per 100 shares (the old name still prevailing although the $2 rate has been superseded); (3) floor or room traders, those who buy and sell for themselves and for their own profit; (4) specialists, who specialize in certain securities and may act as commission brokers or floor traders but who ordinarily do not come into contact with the public; and (5) the odd-lot dealers, who supply or buy from commission brokers a sufficient number of odd lots to equal the full 100 shares, which is the minimum amount that may be purchased or sold on the exchange. While very few houses deal in odd lots, they usually have several representatives on the exchange and probably one-fourth of all the business done on the exchange originates in odd lots. The odd-lot dealer enables the small investor to trade in a few stocks or shares within a small fraction above the price at which large lots are bought and sold.

Brokers who are members of the New York Stock Exchange are controlled rigidly by the constitution, rules and customs of the exchange in an effort to secure fair competition and the proper relationship between the broker and his customer. For example, a broker may not take the side of the market opposite his customer, his charges are regulated, he must report accurately the status of his business to the exchange, he may not advertise securities falsely and the advertising by the firm of itself is regulated explicitly by the exchange. Other American stock exchanges in general are modelled after the New York Exchange. Brokers not connected with organized exchanges are regulated by the laws of their respective States and also by Federal laws. (W. E. S.)

STOCK EXCHANGE or **BOURSE,** a market for the purchase and sale of securities, such as shares, stocks and bonds. Markets for dealing in securities have existed for centuries. They had their beginnings usually in a few men meeting regularly in a certain place, a coffee house or restaurant, who for a commission were prepared to act as intermediaries between buyers and sellers. As their business grew, these men formed themselves into a sort of association, and rules were framed to regulate the conduct of their business. With the growth and wider distribution of wealth, the volume of stock exchange business has steadily expanded, and in the past quarter of a century the growth has been more rapid than in any similar period. Nowadays, practically everyone in highly-civilized countries has dealings with a stock exchange, or bourse as it is called on the Continent. The development of joint stock enterprise could never have reached its present stage but for the facilities which the stock exchanges provide for dealing in securities. Their primary function is to liquefy capital by enabling a person who has invested money in, say, a factory or a railway, to convert it into cash by disposing of his share in the enterprise to someone else. Without the stock exchange, capital would become immobilized, for once invested there would be no means of liquefying it.

London.—London is the greatest of the world's stock exchanges in the range and volume of its transactions. Although New York has made great progress in recent years, London is by far the most international stock exchange in the world, the range of its business covering every corner of the earth and every class and type of security. It was not until the latter part of the 18th century that the London stockbrokers definitely formed themselves into a stock exchange with premises of their own. They had been in the habit of meeting and doing business in the Royal Exchange and neighbouring places, but in 1773 those who had hitherto met at "Jonathan's" (Coffee House), in Change Alley, moved to a room in Sweeting's Alley to which the name of "The Stock Exchange" was formally given, the building becoming known as "The Stock Exchange Coffee House" or "Tavern." Business grew apace and in 1801 a group of members raised £20,000 of capital in 400 shares of £50 each for the purpose of providing an adequate building and acquired a site in Capel Court, Bartholomew lane, which to-day is one of the entrances to the "house."

The new building of the members was opened in 1802. At that time the members of the stock exchange numbered about 500. Rules were drawn up for the conduct of business and for regulating membership of the "house." It was provided that all future members should be admitted by ballot, and members were required to pay a subscription of 10 guineas each for themselves and 5 guineas for their clerks. It was always the general intention that the shares should be held by members but there was always a large number (and until quite recently a majority) of members who did not hold shares. The first extension was made in 1823 when the floor space was nearly doubled by the addition of a second room for dealings in foreign stock. In 1854 the two rooms with some small additions were rebuilt as one in the form of a dome with two transepts. Several subsequent extensions of this building have been made, the principal one being in 1885 when another dome was added. The stock exchange building occupies the greater portion of the triangular area formed by Throgmorton street, Bartholomew lane and Old Broad street. Outwardly it is an uninspiring structure, but the interior is both spacious and handsome.

The premises and property of the London stock exchange are owned by an association called "The Stock Exchange," the capital of which is in 20,000 shares of unlimited liability. On each of these shares £36 has been paid up. No one person may hold more than 200 shares, and only members can be registered as shareholders, except in the case of those who acquired their shares from proprietors who held them before Dec. 31, 1875. The new deed of settlement took effect on Jan. 1, 1876, when the number of proprietors was 268. In 1928 the number was 2,712. When a shareholder dies his shares must be sold to a member within two years. There is a ready market for the shares, for

the dividends are handsome. Recently they have amounted to £10 per share The income of the Stock Exchange (for 1927–28 it amounted to £231,583) is derived from the annual subscriptions of members and their clerks and from entrance fees paid by new members and from rents and investments. The fees have been raised from time to time; members admitted before March 25, 1876, and members admitted with two sureties before March 25, 1879, pay an annual subscription of only £21. The present annual subscription for new members with three sureties, is 100 guineas, and for new members with two sureties—that is to say, a clerk who has served four years in the house—50 guineas The present entrance fees are 600 guineas for a member with three sureties and 300 guineas for one with two sureties. The present entrance fees for authorized clerks—clerks authorized to deal—are 50 guineas and for unauthorized clerks 15 guineas; and their annual subscriptions amount to 100 guineas and 30 guineas respectively. For clerks admitted to the settling room only, no entrance fee is payable, but an annual subscription of 10 guineas is payable for each clerk. These subscriptions and fees are fixed annually by the trustees and managers.

The property of the Stock Exchange is under the control and administration of nine trustees and managers, who are appointed by the shareholders Every five years three retire, and are eligible for re-election. If two vacancies occur they are immediately filled, but in the case of one vacancy it is not filled until the annual meeting. The trustees and managers have no control over business transactions on the Stock Exchange, which are in the hands of the committee for general purposes, numbering 30 members, who are elected annually. This body regulates the transaction of business on the Stock Exchange, makes others and repeals rules and regulations for the same, is charged with the admission and discipline of members and their clerks, and is generally responsible for the good order and government of the members. Its work is so heavy that sub-committees are formed to deal with particular matters.

Securities cannot be dealt in on the Stock Exchange except by permission of the committee, and conditions have to be fulfilled before that permission is granted This is one of the most important new rules of the Stock Exchange. Before the war any security could be dealt in without the permission of the committee, and all that the latter were called upon to do was to fix a special settlement for the completion of the first transactions. Sometimes weeks would elapse before a special settlement was applied for and granted, and sometimes none was applied for or granted. Grave abuses occasionally arose in connection with the marketing of new shares in this way. This licence to deal has been abolished, and the interests of the public are much better protected than they used to be. The discipline of the stock exchange is very strict and the committee deals severely with any members guilty of improper conduct The committee settles disputes between members and also between members and their clients. It has power to suspend or expel a member. Membership is for 12 months only, and thus everyone who wishes to remain a member must apply to the committee for re-election. The year ends on March 24 An important innovation was made in the year 1904, when it was decided to restrict the growth of membership. Prior to that date it was possible to become a member without the nomination of a retiring member. As a result, in active times membership rapidly increased, and when dull times came the competition for business became extremely keen. The rule passed in that year virtually stopping the growth of membership is the most important rule affecting the Stock Exchange passed in the present century In the ordinary way the only method by which a person may become a member is to obtain a nomination (by purchase) from an existing member who must retire in his favour. Nominations may be obtained from a former member, or, if he has not disposed of his nomination, from the legal personal representative of a deceased member. Nominations, which are personal and non-transferable, are usually purchased, and the cost may be as high as £2,000. To-day (1928) the cost is about £1,150. A candidate for membership must be recommended by three members, who become sureties for him during the first four years in £500 each, or £1,500 altogether. A certain number of clerks who have completed four years' service are admitted each year without nomination. The number of such admissions is left to the discretion of the committee; in 1927–28 the number of such new admissions was 20.

The fact that the Stock Exchange is owned by the shareholders and controlled by their elected trustees and managers, while a separate body, the stock exchange committee, appointed by the members, controls and regulates business, has constituted what is known as dual control. The committee has no funds of its own and cannot initiate or control the expenditure of the money subscribed by the members. While the arrangement has worked remarkably smoothly, it is nevertheless anomalous and various efforts have been made to terminate it But none of them has succeeded. Since Nov. 23, 1904, every member admitted with two sureties has been obliged to become the owner of at least one share and every member with three sureties must hold three shares; under this arrangement the dual control is not likely to be abolished for a long time to come. One of the most interesting innovations on the stock exchange has been the introduction in 1928 of a pension scheme for members' clerks. The scheme was floated by the Clerks' Provident Fund with the blessing of the committee, but it is really unofficial and voluntary Members, however, have generously supported the scheme, which in time will no doubt be generally adopted.

The London Stock Exchange contains two notable monuments, the Boer War memorial and the memorial to those who fell in the World War.

By custom, each market has a special place allotted to it; for instance, the space immediately in front of the World War memorial is the market for British Government securities and other gilt-edged stocks. Dealers or jobbers in these securities take up their posts in this space every day, and dealers in other classes of securities similarly occupy the floor space allotted to their particular markets. In this way the locality of a market can be readily and easily found by the brokers who go to the house to buy or sell securities for their clients. There is an important distinction between brokers and dealers. Brokers are not allowed to deal on their own account, nor can dealers act as brokers Their functions are defined by a rule which was last amended in 1908 and took effect as from Feb. 1, 1909 The dealer or jobber occupies a position similar to that of the wholesale dealer in commodities He keeps a stock of particular securities, say oil shares, and his function is to buy oil shares when they are offered to him and to sell them if they are wanted He quotes two prices for a share, a buying price, which is the lower, and a selling price, which is the higher, and the difference represents his profit. A broker acts for the public which desires to buy or sell securities. Ordinarily, both for buying and selling securities, though under certain circumstances only for buying, a commission is charged. On receiving an order to deal in a certain security, a broker goes to a jobber in that market, and asks for a price, mentioning the amount of stock which he desires to deal in, but he does not disclose whether he is a buyer or a seller. The jobber "makes a price," *i e.*, gives two prices; at one he is prepared to buy and at the other to sell. If the broker is satisfied with the price, or if it conforms with the price limit fixed by his client, he will tell the jobber that he sells or buys as the case may be, at the price quoted. On the other hand, if he is dissatisfied, the broker will ask for a closer price, and if the jobber is anxious to do business, will make a closer price, and the bargain is then made. A jobber's business requires special qualifications. It has been said that a jobber is born, not made. There is much truth in this. The most successful jobbers have a flair for the business. They must be men of good nerve, cool judgment, and ready to deal under any ordinary conditions. They must be men of financial standing, considerable experience, with an understanding of market psychology.

The number of members (1928) is nearly 4,000 and these employ about 2,000 clerks who have the right of entry to the house. The hours of business are nominally from 10.45 A.M. to 4 P.M. No bargains, however, are marked after 3.30 for inclusion

in the lists published in the evening of the same day. Late bargains are marked and published the following day. During the war and for some time after, it was compulsory to mark all bargains, but owing to pressure of business, this excellent rule was abolished. Bargains are to-day recorded at the option of dealers or on request by brokers for their clients. During the period of compulsory marking, the stock exchange had to issue a list of securities which were not included in the official list. This list is known as the supplementary list. Fortunately this continues to be published, though it is not so useful as it might be owing to optional marking. Since the war broke out no sessions have been held on a Saturday, and it seems unlikely that they will ever be resumed unless the public insistently demands it. This is improbable, for the reason that since 1914 Saturday has become to an increasing extent a day of clearing up. The banks have shortened their hours of work on a Saturday by closing at noon instead of at 1 o'clock, and this would have to be altered before the stock exchange would be justified in opening on a Saturday. The movement towards making Saturday more and more a holiday is the result of the increasing intensity of business. The motor car and the telephone make it possible to transact far more business in a day than was possible 30 years ago, and the hustle of modern business life renders more rest essential. Moreover, on the stock exchange great improvements in working practices have been introduced in recent years, and the efficiency of dealers' and brokers' staffs is much higher. The volume of work they transact in a day is far larger than before the war, the population of investors having enormously increased. Except in the gilt-edged market, every bargain a broker executes for his client is "for the account," unless otherwise specified. This means that the bargain will be completed—*i.e.*, the stock handed over and paid for—on the next settling day. The usual period of the account is a fortnight, but there are four 21-day accounts in the course of a year. Settling days are usually fixed for a Thursday, the passing of tickets—ticket day—takes place on a Tuesday, and making-up day is Monday, prices for the settlement of current securities being fixed at 11.30 A.M. Brokers on executing an order for a client send to him a contract note which sets forth the details of the transaction, the price obtained or to be paid, the amount of brokers' commission, of stamp and transfer fee, and the amount of the contract stamp. Later, as settlement day approaches, a further note is sent to a client who has bought stock, requesting him to forward the purchase money. In the case of a speculative transaction the same procedure is adopted, except that the client, if he has bought stock, is required not to pay the total purchase money, but merely the difference between the price which he gave and the price fixed on making-up day if the latter is lower than the former. If, however, the security has risen in price, the client receives a cheque for the difference between the price at which he bought and the making-up price. A rate of interest or contango, is charged for the facilities of buying and holding stock without paying for it. Contangoes vary in accordance with the current rate of interest. Usually they are higher on the more speculative securities than on the investment type. The rate of a contango is also affected by the state of the "open" account, as it is called, in a particular share.

If there is a large "bull" account—*i.e.*, a large number of speculative purchases for a rise—and dealers are anxious to discourage further buying, the contango may rise to 10% or more. Rates are generally lower on the more active shares and higher on the less active, which means that there are fewer people ready to carry the latter type of share. Shares in which the market is narrow and difficult, cannot be contangoed. Some speculators sell for a fall as well as buy for a rise. Facilities for technically lending shares to speculators who have sold them are also provided, and the rate of interest charged for lending stock is called "backwardation." This varies with the size of the "bear" account, as a speculative sale is called. If the "bull" account open in a stock is larger than the "bear," there will be a contango rate and no backwardation rate, and *vice versa.* Since the war the facilities for carrying over bargains from account to account have been greatly reduced, but speculation has not diminished. The speculators have merely changed their methods. The banks, instead of lending money to members of the stock exchange as largely as formerly, for relending to their clients, now lend freely to their own customers on stock exchange collateral. This is a safer method, for a bank rarely allows its client to borrow more than he can repay. Another popular device of speculators is to gamble during one account only. If markets are rising, a speculator will buy at the beginning of an account and sell towards the end, and *vice versa.* Speculation is cheaper in this form, for by completing his operation in one account, the operator pays only one commission. During one of the periods of stock exchange depression before the war a movement was started and carried to a successful conclusion for fixing a scale of minimum commissions. It was fixed on a generous scale, for after the war little change was made in spite of the great increase in all other prices and costs. The inflation of capital values, of course, helped to swell considerably the volume of business. (C. J. Mi.)

New York.—The New York Stock Exchange traces its origin to a small group of stock-brokers in New York who, shortly after the American Revolution, bought and sold securities under an old buttonwood-tree which once stood in lower Wall street. In 1792 this group of curb-brokers signed an agreement as to the methods to be followed in the business; in 1817 the gradual increase in the volume of trading led to the formation by these stock-brokers of a definite association, and the hiring of indoor quarters for their market.

The purpose of the Exchange, then as now, can best be explained by reference to its present constitution, which declares "Its objects shall be to furnish exchange rooms and other facilities for the convenient transaction of their business by its members; to maintain high standards of commercial honor and integrity among its members; and to promote and inculcate just and equitable principles of trade and business." Legally, the Exchange is a voluntary association; it has never obtained a charter or assumed the form of an incorporated body. Ever since the reorganization of the Exchange in the '70s, membership has been limited to 1,100 members; thus, one wishing to become a member of the Exchange must purchase a membership (or "seat") from the estate of a deceased member, or from some living member who is retiring from the business. Candidates for membership in the Exchange must also be formally elected by the committee on admissions, after this committee has investigated their previous business careers and records. They must also agree without qualification to obey and abide by the constitution and rules of the Exchange, carrying as they do powers of broad and sweeping character over all phases of their business as Exchange members.

The legislative and judicial powers of the Exchange are vested in its governing committee of 42 members; each governor holds office for four years and each year ten governors come up for election. In addition to the governors, the officers of the Exchange consist of a president, treasurer, assistant to the president, secretary, first assistant secretary, accountant and economist. Routine work of the Exchange is supervised by standing sub-committees of the governing committee, while special or temporary matters may be handled by special sub-committees of that body. Where circumstances have rendered it more convenient and desirable, certain regular routine functions of the market have been organized in the form of subsidiary corporations, all the stock of which is held by the governors as trustees for the members; for example, the Stock Clearing Corporation handles and supervises the work of clearing and settling Exchange contracts, etc., the New York Quotation Company supervises the distribution by tickers of the quotations which are collected on the Floor of the Exchange; the New York Stock Exchange Building Company holds title to the physical assets of the Exchange; and the New York Stock Exchange Safe Deposit Company provides safe-keeping facilities for the securities held by Exchange members.

The constitution and rules of the New York Stock Exchange were first drafted in 1817. During the intervening century, the New York securities market was probably subjected to intense

pressure from a greater variety of sources than any great securities market in history. In addition to foreign and domestic wars, there was added experience with all manner of currency difficulties, booms, depressions, periods of intense activity and periods of practical stagnation. In consequence the code of rules which govern Exchange members in their relationships and their business has been fully tested by extreme and various forms of economic pressure, and they are for this reason all the more fundamentally adequate and sound to-day.

In 1928 the market value of securities listed on the New York Stock Exchange amounted to approximately $82,000,000,000. Ready purchasing and selling within this enormous field of investment were facilitated by the branch offices of Stock Exchange member firms, connected with the New York head offices by private wires; there were in 1928 962 of such branch offices located in 292 cities representing 41 States of the Union and four foreign countries. Share quotations were distributed on 5,547 stock tickers and bond prices on 889 bond tickers.

To study the gradual accession of different sorts of securities to the New York Stock Exchange market is to review the whole panorama of American economic development for more than a century past. The original New York securities market sprang from the trading in Alexander Hamilton's U S 6% Government bond issue which funded the revolutionary debt, as well as dealings in the original stock of the first U.S. Bank. Shortly afterward, shares of the earliest fire and marine insurance companies and of the earliest local incorporated banks were added to the list. Another wave of economic development brought into the market many State bonds which represented canals and turnpikes, the construction of which the various States of the Union were undertaking. In 1836 occurred the first trading in steam railway securities, which for the greater part of a century was to constitute the principal occupation of the market, as the enormous railway systems spread across the great plains and over the Rockies to the Pacific. The discovery of petroleum in Pennsylvania and coal in this and other eastern States was also soon reflected in the market by the appearance there of oil and mining shares After the Civil War, in addition to the great railway consolidations of the time, industrial and utility securities were listed. A final stage was reached in 1915, when the market began not only to reabsorb and distribute among American investors American securities long held by the creditor countries of Europe, but also to list foreign government (and subsequently foreign corporate) securities of Europe and other continents. Thus to-day the New York Stock Exchange is not only the leading security exchange of America, whose listings broadly reflect the whole panorama of American economic life, but also an international securities market of constant activity and steadily expanding scope.

(E. H. H. S.)

Paris.—The Paris bourse, unlike the London stock exchange, is subject to Government control and supervision. It is an influential body, and is an institution of great financial and political strength *Agents de change,* who are the members of the bourse, are nominated by decrees countersigned by the minister of finance or by the minister of commerce and industry. The *agents de change* must be Frenchmen, and in full possession of civic and political rights They form the aristocracy of the bourse. They constitute what is known as the *parquet,* a privileged space on the floor of the bourse to which only they have access. The rest of the bourse is known as the *coulisse.* The *parquet* of the bourse elects a *chambre syndicale* or committee, which makes the rules for the conduct of business. Although in law the liabilities of individual members are no concern of the bourse, in practice the *chambre syndicale* meets the liabilities of any defaulting member. Each member owns what is called a charge, for which he has paid a sum varying from 1,500,000 f. to 2,000,000 f. to his predecessor by a private arrangement. In addition a member must deposit 250,000 f. as caution money and 120,000 f. in the *caisse commune* of the *chambre syndicale. Agents de change* enjoy a monopoly in regard to various kinds of legal business, and they possess other privileges not shared by members of the *coulisse.* They may buy or sell certain securities for cash, whereas the *coulissiers* may only deal for delivery in the settlement. Securities dealt in by the *coulisse* are known as *valeurs en banque,* and the *coulisse* is often described as the *marché en banque.* The *agents de change* issue the official price list of securities each day, but the *coulisse* issues an unofficial list of its own. Being less restrictive and broader, the *coulisse* provides much the bigger market, and its business is much larger in volume than that of the *parquet.* The market for foreign securities is in the *coulisse,* some of the members of which are very wealthy. Practically all Continental securities are in bearer form; that is to say, they are not registered or inscribed, but change ownership by passing from hand to hand. Great care is taken to protect dealings in bonds which may pass so easily. The *agents de change,* for instance, publish the *Bulletin officiel des oppositions,* which gives the designations and the numbers of securities dealings in which are suspended because they have been stolen or lost. It is imperative for those dealing in Continental bonds to examine this list before taking delivery of bonds in case they may be on the "stopped" list. As in London, the settlement of transactions takes place every fortnight, in the middle and at the end of the month. Dealings in French Government securities, however, are paid for, and the securities are taken up, at the end of every month. The Paris Bourse has not the same international importance as London. Before the war the French investor confined his investments to French securities. Russian bonds, certain Brazilian and Argentine and other South American securities, and a few United States bonds, Rio Tinto copper shares, oil shares, mostly Russian, and South African gold mining shares Turkish and Egyptian securities have had a certain vogue, as well as sundry issues of the lesser European States and municipalities. Occasionally the French have taken to big speculative ventures. Inspired by the success of the Suez canal investment, for instance, many Frenchmen supported the Panama Canal Company, but huge sums were lost in that enterprise That disaster gave a severe blow to speculative enterprise in France, where it has never been really liked, for the average Frenchman prefers to invest, and not to speculate or gamble. The banking houses of France are all represented in the bourse, and much of the investment business of the bourse is really done through the banks. During the period of currency depreciation in France a great deal of money was invested abroad in spite of the prohibition on the export of capital, but the major part of this money was invested in very high-class British and American securities, and an inconsiderable part was deposited with banks at interest. Business begins on the Paris bourse at 11 o'clock and lasts until 3 o'clock It is usually opened on Saturdays, but in the summer months it remains closed on that day. Unofficial business may be conducted outside the official hours, and at times many transactions are entered into after the bourse has been closed.

The last great reorganization of the Paris bourse took place in 1898. There had been much criticism of the monopoly given to the 60 stockbrokers in Paris. The number was increased to 70, and a new table of brokerage was drawn up, and other articles were modified. It effected, however, no real change in the bourse organization, and the public demand for real reorganization was really turned, but not satisfied However, the *parquet* wisely allowed certain breaches of their monopoly privileges, which served in effect to reduce the dissatisfaction with their monopoly conditions. *Remisiers* are allowed to make contracts by themselves provided that they record every day their transactions on the pad of an agent, who in return for a percentage of the brokerage hands them an official contract. Another violation of the law which has been accepted is the transaction of business for future delivery by the *parquet.* It was due to the competition of the curb-brokers.

Germany.—The Berlin *Börse,* like the Paris bourse, is subject to Government control and to legal enactments. It does not enjoy the freedom of the London or New York stock exchange, and speculation is frowned upon and discouraged on the German bourses. The official hours of the bourse are from 12 to 2 and on Saturdays from 11 to 1 o'clock. Dealings, however, are al-

lowed to take place for 30 minutes after the official closing hour, and the prices are published in the papers. These quotations, however, are not official, and are not subject to the control of the bourse committee. During the months of July and August, which are regarded as holiday months, no session of the bourse is held on Saturdays. There is no entrance fee for a new member, and no fixed annual subscription. The finance committee of the bourse fixes the annual payment of a member according to the amount and volume of business of each firm. Certain fees are charged in respect of the partners who wish to visit the stock exchange, and, as in London, fees have to be paid for each authorized clerk and employee. The application of a new member must be supported by three members of the bourse, and each member supporting the application has to guarantee the candidate in the sum of 5,000 Reichsmarks. Members of the Berlin bourse are not necessarily rich men; membership may be granted to men of relatively small resources. The brokers (*makler*) are appointed more out of regard for their character than for their resources. They carry on business under conditions laid down by the Government, and it is subject to the supervision and control of high State authorities. In 1896 legislation was passed which severely restricted business on the Berlin bourse. It was intended to put a check on speculation in stocks for future payment and delivery. This forced speculators to transact their business abroad, especially in London, Brussels and Amsterdam. Since the war conditions have become freer. The method of doing business on the Berlin bourse is peculiar. Orders to buy or sell securities are settled at official prices which are fixed every day. The fixing of these prices is determined by the relation of the current demand to the supply. The public have no trouble, therefore, in checking the price they pay or receive, as the case may be. The Frankfort bourse holds two sessions, a morning and an evening session, but though dealings are carried on later than in Berlin, it is not a more important stock exchange. The securities dealt in are similar, and the official prices quoted are virtually the same. During the stabilization process, the bourse was overrun by "free" brokers and jobbers—a result of large-scale dismissals of clerical staffs by the banks. The bourse authorities, however, took steps to check this influx, and the "free" jobbers and brokers largely declined. Improvements were made at the same time in the technical equipment and practices of the bourse, greatly facilitating the clearing system of dealing in securities. Business is nowadays done on normal lines, but the market has not recovered its former activity and importance owing to the great destruction of capital caused by the inflation of the currency during and after the war.

Amsterdam.—The Amsterdam bourse as it exists to-day was founded in 1876, and up to quite recent times its members, like those of the London stock exchange in earlier days, had to transact their business in a building which also housed persons engaged in commercial business. In 1876 the bourse consisted of 435 members, whereas the present (1929) number is nearly 800; the entrance fee, which was then 25 guilders, is now 2,000 guilders, and in the same period the annual subscription has been raised from 30 to 80 guilders. The bourse, members of which must be Dutch or nationalized Dutch, is open from 1.30 to 2.45 (Amsterdam time). There are members and authorized clerks, as in London, but there is no line of demarcation between brokers and jobbers. Some firms combine broking and jobbing, and others work as bankers and brokers. The banks are all members of the bourse, and have their clerks therein, but they also do business through other members. Transactions are all for cash, except those in the shares of the Netherlands Trading Company, in which there is a monthly settlement. Three quotations are made during the day in less active stocks, on the basis of which business is done. The Amsterdam bourse is particularly interested in oil shares, especially Royal Dutch; the shares of various Dutch East Indies trading and planting companies; the securities of one or two leading Dutch industries; and one or two artificial silk shares. Before the World War an important international market existed. This disappeared during the war, but lately a number of Belgian, French and German industrial shares have been introduced, and for some of these there is an active market. The American railway market, however, which before the war was one of the most active in the bourse, has now dwindled to small proportions. A large number of foreign bonds are now dealt in, and a part of many of the placings of German and other foreign bonds in the United States has also been issued in Amsterdam, and they are quoted on the bourse there. In recent years the yield from the duty payable on stock exchange transactions has varied from rather less than 5,000,000 florins to nearly 6,000,000 florins.

(C. J. Mi.)

STOCKHOLM, the capital of Sweden, on the east coast, not far south of the junction of the Baltic Sea and the Gulf of Bothnia. The population of Stockholm in 1751 was 61,040; in 1850, 93,070; in 1880, 176,875; in 1900, 300,624; in 1928, 466,000.

Origin.—Before Stockholm arose, Björkö, Sigtuna and Uppsala were places of great importance. Björkö ("the isle of birches"), by foreign authors called Birka, was a kind of capital where the king lived occasionally at least; history speaks of its relations with Dorestad in the Netherlands, and the extensive refuse heaps of the old city, as well as the numerous sepulchral monuments, show that the population must have been large. But though situated at a central point on Lake Mälar, it was destroyed, apparently before the beginning of the 11th century (exactly when or by whom is uncertain); and it never recovered. Sigtuna, lying on the shore of a far-reaching northern arm of Lake Mälar, also a royal residence and the seat of the first mint in Sweden, where English workmen were employed by King Olaf at the beginning of the 11th century, was destroyed in the 12th century. Stockholm was founded by Birger Jarl, it is said, in or about 1255, at a time when pirate fleets were less common than they had been, and the government was anxious to establish commercial relations with the towns which were now beginning to flourish on the southern coast of the Baltic. The city was originally founded as a fortress on the island of Stadholm. The castle was erected at the north-eastern corner, and the city was surrounded with walls having fortified towers on the north and south. It came to be called Stockholm ("the isle of the log," Latin *Holmia*, German *Holm*); the true explanation of the name is not known. During the middle ages the city developed steadily, and grew to command all the foreign commerce of the midlands and north, but it was not until modern times that Stockholm became the capital of Sweden. The mediaeval kings visited year by year different parts of the kingdom.

Situation.—Stockholm is famed for the beauty and physical characteristics of its situation. The coast is here thickly fringed with islands (the *skärgård*), through which a main channel, the Saltsjö, penetrates from the open sea, which is nearly 40 m. from the mainland. A short stream with a fall normally so slight as to be sometimes reversed by the tide, drains the great lake Mälar into the Saltsjö. The scenery of both the lake and the *skärgård* is similar, the numerous islands low, rocky, and generally wooded, the waterways between them narrow and quiet. The city stands at the junction of the lake and the sea, occupying both shores and the small islands intervening. From the presence of these islands a fanciful appellation for this city is derived—"the Venice of the North"; but actually only a small part is insular. There are three main divisions, Staden, the ancient nucleus of the city, properly confined to Stadholmen (the city island) which divides the stream from Mälar into two arms, Norrström and Söderström; Norrmalm on the north shore of the channel, and Södermalm on the south.

Staden.—Ancient origins are apparent in the narrow and winding streets, though the individual houses are not very old, owing to the ravages of frequent fires. A few, however, preserve antique narrow fronts with gables, as in some of the North German towns. The old market, still called Stortorg (great market) is now one of the smallest in Stockholm. At the north angle of the island is the Royal Palace (*Slott*). The original building was destroyed by fire in 1697, the body of Charles XI. being with difficulty rescued from the flames. A new palace after designs of Nicodemus Tessin the younger (d. 1728) was not completed, owing to wars and the general distress, until 1754; while a res-

toration carried out in 1901 included many ornamental details devised by the architect and executed at the expense of King Oscar II The new town hall designed by Östbergand recently completed combines Swedish traditional styles with Italian influences.

West of the palace are the offices of the majority of the ministries, some of them in the former buildings of the Royal Mint. Beyond these, on the west side of the island, is a square named from the palace on its northern side, the Riddarhustorg. The Riddarhus (house of the nobility) was the meeting-place of the Council of the Nobles until 1866, and its hall is adorned with the armorial bearings of noble families. The north fore-court has a statue (1890) of Axel Oxenstjerna, the chancellor, by J. Borjeson In Riddarhustorg is a statue of Gustavus Vasa, unveiled in 1773 on the 250th anniversary of his accession. South-west of the Royal Palace is the Storkyrka (great church), dedicated to St. Nicholas, the oldest church of Stockholm, greatly altered from its original state. The date of its foundation is 1264; but it was practically rebuilt in 1726–1743. Within it is richly adorned with paintings and wood-carving. Staden is the commercial centre of the city. At the broad shipping quay (*Skeppsbro*) which flanks the palace on the north and east, most of the seagoing steamers lie; and the exchange, custom-house, numerous banks and merchants' offices are in the immediate vicinity. Riddarholmen (nobles' island), lying immediately west of Stadholmen, contains the old Franciscan church (*Riddarholmskyrka*), no longer used for regular service, which since the time of Gustavus Adolphus has been the burial-place of the royal family. It has recently been restored, and contains mediaeval paintings, and many trophies of the European wars of Sweden. On one side of it stands the old house of parliament; on the other a statue of Birger Jarl, the reputed founder of the city On Riddarholm also are various government offices, and most of the steamers for Mälar and the inland navigation lie alongside its quays

THE ENGELBREKTSKYRKAN, NORRMALM, A CHURCH NAMED AFTER ENGELBREKT, SWEDISH PATRIOT, WHO WAS ASSASSINATED IN 1436

Norrmalm.—Staden is connected with Norrmalm by the Norrbro (north bridge) and Vasabro, the first crossing Helgeandsholmen (the island of the Holy Spirit), on which are situated the new Houses of Parliament and the Bank of Sweden A third bridge connects with the main thoroughfare of Norrmalm, Drottningsgatan (Queen Street). The Norrbro gives upon Gustaf-Adolfs-Torg, where a statue of that king stands between the royal theatre, royal opera house and the palace of the crown prince Norrmalm is the finest quarter of the city, with broad straight streets, several open spaces with gardens, and handsome buildings. East and north of the theatre royal, the Karl-den-Tolftes-Torg and Kungsträdgård (royal garden) form the most favoured winter promenade. There are a statue of Charles XII. and a fountain with allegorical figures, by J. P. Molin, also a statue of Charles XIII , and in the small Berzelii Park close at hand one of the chemist J J. Berzelius Near Drottningsgatan is the Klara church, the burial-place of the poet K. M. Bellman, and west of this, occupying one side of a square, is the central railway station In the building of the academy of science is the national museum of natural history, including mineralogical, zoological, and ethnographical departments.

Other Districts.—On the island of Kungsholm, S. of Vasastad, are the Caroline medical institute, several hospitals, including the Serafimer (1752), the royal mint and factories Östermalm, lying east, that is, on the seaward side, of Normalm, is a good residential quarter, containing no public buildings of note, save the barracks of the Swedish Guards and the fine royal library, which is entitled to receive a copy of every work printed in Sweden. The library stands in the beautiful park of Humlegård (hop-garden), in which is also a statue of Linnaeus. South of Östermalm, and east of the Kungsträdgård and Staden, lies the peninsula of Blasieholm (formerly an island) and, connected by bridges, the islands of Skeppsholm and Kastellholm, the three forming the foreground in the beautiful seaward view from the Norrbro. On the first is the national museum (1866), a Renaissance building, containing historical, numismatic and art-industrial collections, with ancient and modern sculptures, picture-gallery and engravings. The numismatic collection is notable for its series of Anglo-Saxon coins. About 11,000 pieces came from the island of Gotland, some dating from 901–924, but the majority are later. In front of the museum is a bronze cast of the famous group of J. P. Molin (1859), the Bältespännare (belt-bucklers), representing an early form of duel in Scandinavia, in which the combatants were bound together by their belts.

East of Skeppsholm an inlet, Ladugårdslandsviken, so named from the proximity of the former royal farm-yard (*ladugård*), and bordered on the mainland by a quay with handsome houses called Strandvägen, throws off a narrow branch (Djurgårdsbrunnsviken) and separates from the mainland an island about 2 m. in length by ¾ m broad This is mainly occupied by Djurgården (the deer-park), a beautiful park containing the buildings of the northern museum, a collection of Scandinavian costumes and domestic and agricultural utensils, and a biological museum housed in a wooden building imitating the early Norwegian timber churches (*stavekirke*). Here also is Skansen, an ingenious reproduction in miniature of the salient physical features of Sweden with its flora, fauna and characteristic dwellings inhabited by peasants in the picturesque costumes of the various districts. Both the northern museum and Skansen were founded by Dr. Arthur Hazelius (1833–1901). There is a bust of the poet K. M. Bellman, whose festival is held on the 26th of July. Södermalm, the southern quarter, is principally residential.

The beautiful environment of sea and lake is fully appreciated by the inhabitants. To the north of the city, accessible by rail and water, are the residential suburbs of Haga and Ulriksdal, with royal *chateaux,* and Djursholm. Saltsjobaden, 9 m east of Stockholm, on Baggensfjord, is the nearest and most favoured seaside resort, but Dalarö (20 m. south-east) and Nynäshamn (39 m. south) are much frequented Vaxholm, 12 m. north-east by water, is a pleasant fishing-village where numerous villas have been built.

Institutions.—Stockholm is the centre of government and the usual residence of the king; in summer he usually occupies one of the neighbouring country palaces The city is the seat of the high court of justice (*Hogsta Domstolen*) and of the court of appeal for the northern and midland districts (*Svea Hofrätt*). As regards local government, Stockholm is a *län* (administrative district) in itself, distinct from the rural *län* of the same name, under a high governor (*öfverståthållare*) and deputy, with departments for secretarial work, taxation and police. The city is in the diocese of Uppsala, but has a separate consistory, composed of the rectors of the city parishes, the president of which is the rector of St. Nicholas (*Storkyrka*). Stockholm has no state university. A private university (*Högskola*) was founded in 1878, and was brought under state control in 1904. The president of the governing body is appointed by the government, while the appointment of the remaining members is shared by the Swedish Academy, the Academy of Sciences, and the City Council. The faculties are four—philosophy and history, philology, mathematics and natural sciences and jurisprudence. The Caroline Institute (*Karolinska Mediko-Kirurgiska Institut*) is a medical foundation dating from 1815, which ranks since 1874 with the state universities of Uppsala and Lund in the right to hold examinations and confer degrees in its special faculty. Special and secondary education is highly developed; there are schools of agriculture, min-

BY COURTESY OF SWEDISH STATE RAILWAYS

THE CITY HALL AT STOCKHOLM, COMPLETED IN 1922

ing and forestry, technical schools, a veterinary school, a school of pharmacy, etc. Among the public colleges under state control, one, the Nya Elementarskolan, was founded experimentally in 1828, after the Education Committee of 1825–1828, among the members of which were Tegner and Berzelius, had reported on the want of such schools. This school retains its separate governing board; whereas others of the class are under a central board. The control of the primary schools in the parishes is similarly centralized; whereas in Sweden generally each parish has its school-board.

Stockholm is the seat of the principal learned societies and royal academies. (*See* SWEDEN.) There are schools of painting, sculpture and architecture under the direction of the Royal Academy of Arts; a conservatory of music under that of the Royal Academy of Music; and experimental gardens and laboratories under the Royal Society of Agriculture. The Natural History Museum, the observatory and meteorological office, and the botanical gardens are under the supervision of the royal academy of sciences. Minor collections deserving mention are the museums of the geological survey and the Caroline Medical Institute, and the archives in the record office (*Riksarkivet*).

Among places of entertainment, the royal theatre is managed by a company receiving a state subsidy. The Dramatic Theatre (*Dramatiska Teatern*), in Kungsträdgårds-Gatan, the Swedish (*Svenska*) theatre in Blasieholms-Gatan, and the Vasa theatre in Vasa-Gatan may also be mentioned. The Djürgård is the principal place for variety entertainments in summer. Several of the leading sporting clubs have their headquarters in Stockholm. An annual regatta is held early in August by the Royal Swedish Yacht Club (*Svenska Segalsällskapet*). A harbour much frequented by yachts is Sandhamn in the outer *skärgård*. The Stockholm General Skating Club (*Almänna Skridskoklubb*) is the leading institution for the most favoured winter sport. A characteristic spectacle in winter is the tobogganing in the Humlegård on holidays. The principal athletic ground is the Idrottspark (Sports Park), on the north side of Östermalm, with tennis courts and a cycling track, which may be changed into a skating-rink in winter. There is a similar park at Djursholm. A stadium in Swedish mediaeval style, seating 15,000, was opened for the Olympic Games in 1912.

Commerce.—The industries of Stockholm are miscellaneous. The value of the output of these is nearly thrice that of Malmö or Gothenburg, the next most important manufacturing towns, and the industries of Stockholm exceed those of every *län* (administrative division) except Malmöhus. The iron and steel industries are very important, including engineering in every branch, and shipbuilding. Factories for articles of human consumption (*e.g.*, breweries and tobacco works) are numerous; and cork, wood, silk, chemical and leather works may also be mentioned. Fine ware is produced by the Rörstrand and Gustafsberg porcelain works. In addition there are various government works, as the mint and printing works. Stockholm is the first port in Sweden for import trade, but as regards exports ranks about level with Malmö and is exceeded by Gothenburg, Stockholm having proportionately little share in the vast timber export trade. Over 50% of the tonnage using the port is Swedish. Vessels of 23 ft. draught can go up to the city (Skeppsbro and Blasieholm quays), and there is an outport at Värtan on the Lilla Värtan channel to the north-east. The port accommodation was enlarged in 1925, and the new Hammarby channel, for vessels up to 3,500 tons, was completed. A new dock for large vessels was constructed in 1926, and further harbour works on Lake Mälar are projected. In 1924 the railway station was rebuilt.

See P. R. Ferlin, *Stockholms Stad* (Stockholm, 1854–58); C. Lundin and A. Strindberg, *Gamla Stockholm* (Stockholm, 1882); C. Lundin, *Nya Stockholm* (Stockholm, 1890); G. Nordensvan, *Mälardrottningen* ["the queen of Mälar"] (Stockholm, 1896); E. W. Dahlgren, *Stockholm, Sveriges hufvustad skildrad* (Stockholm, 1897, issued by the municipal council on the occasion of the Stockholm Exhibition, 1897).

STOCKINETTE. A term strictly denoting a particular variety of knitted or hosiery fabric composed of wool, cotton, silk or artificial silk, and produced as a tubular fabric and in a continuous piece of indefinite length on a knitting machine of the circular type. The fabric may be used in its tubular form, or may be cut lengthwise and opened out into single width, to be made up into the numerous garments for clothing and other articles for domestic use.

STOCKJOBBER: *see* JOBBER, STOCK EXCHANGE.

STOCKMAR, CHRISTIAN FRIEDRICH, BARON VON (1787–1863), Anglo-Belgian statesman, who came of a Swedish family, was born at Coburg on Aug. 22, 1787. He was educated as a physician, and became attached in 1816 to Prince Leopold of Saxe-Coburg-Gotha on his marriage to Princess Charlotte of England. When she died next year he remained Leopold's private secretary, controller of the household and political agent, until the prince became in 1831 king of the Belgians. His disinterestedness and profound acquaintance with English and European social and political questions impressed themselves on all who were associated with him. In 1831 he retired to Coburg, in order not to excite Belgian jealousies by residing at court as confidential adviser, but he continued to be Leopold's right-hand man. In 1837 Leopold sent him to England as adviser to the young Queen Victoria, and in the next year he accompanied Prince Albert (afterwards Prince Consort) on his tour in Italy. He won the complete confidence of the prince as well as of the queen, and on their marriage in 1840 he became their trusted though unofficial counsellor, dividing his time between England and the Continent. He died at Coburg on July 9, 1863.

See the articles on VICTORIA, QUEEN; and ALBERT, PRINCE CONSORT. Selections from Stockmar's papers were published by his son Ernest in 1872, and a biography by Juste appeared at Brussels in 1873; *see* also *The Letters of Queen Victoria* (1907).

STOCKPORT, a municipal, county and parliamentary borough of Lancashire (in part) and Cheshire (in part), England, 6 m. S.E. of Manchester. Pop. (1921) 123,309. The boundaries of Manchester and Stockport meet in Levenshulme. The ancient town stood on the slopes of a narrow gorge where the rivers Tame and Goyt join to form the Mersey, but the modern town has extended on to the more level land above. There are many river bridges and a lofty railway viaduct bestrides the gorge. Stockport is served by the L.M.S., L.N.E. and Cheshire Lines railways. Electric tramways connect it with Manchester. The town is an important industrial and railway centre. Its industries include cotton and felt hat manufactures, the construction of machinery for the cotton trade, motor and electrical engineering, bleaching and dyeing, and the manufacture of leather and of foodstuffs. The public buildings include the church of St. Mary (built about 1817) with portions of earlier date and a Decorated east window; St. George's church (1897); St. Mark's church (1921); the town hall (1908), designed by Sir Brunwell Thomas; the central library (1913), the grammar school (1916) and the Hall of Memory. In all there are 214 ac. of parks. The Kinder waterworks (1912) have a reservoir covering 44 acres. The old Stockport grammar school was founded in 1847 and the Stockport Sunday school (founded 1784) is one of the largest in the kingdom. Stockport returns two members to parliament. It was enfranchised in 1832, incorporated 1835, and became a county borough in 1888. Richard Cobden represented Stockport in parliament from 1841 to 1847.

During the Roman occupation there was a small military station on the site of Stockport, at the junction of two Roman roads. The etymology of the name may be Saxon, but there is no evidence of a Saxon settlement, and the place is not mentioned in Domesday. A castle was in existence in the 12th century, but is not mentioned after 1327. Stockport (Stokeporte, Stopport, Stopford) was made a free borough by a charter of Robert de Stokeport about 1220. Thus Stockport was not a true municipal borough until formally incorporated under the Municipal Corporations Act of 1835.

STOCKS, a wooden structure formerly in use both on the continent of Europe and in Great Britain as a method of punishment for petty offences. The culprit sat on a wooden bench with his ankles, and sometimes his wrists or even neck, thrust through holes in movable boards, generally for at least several hours. That stocks were used by the Anglo-Saxons is proved by their often figuring in drawings of the time (*see* Harleian mss.

No 65). The second Statute of Labourers (1350) ordered the punishment for unruly artisans. It further enjoined that stocks (ceppes) should be made in every town between the passing of the act and the following Pentecost. The act appears to have been ill observed, for in 1376 the Commons prayed Edward III. that stocks should be set up in every village. Though never expressly abolished, the punishment of the stocks began to die out in England during the early part of the 19th century, though there is a recorded case of its use so late as 1865 at Rugby. In many villages may still be seen well-preserved examples of stocks, in some cases with whipping posts attached. In the United States stocks were of frequent use in the 18th century, more particularly in the New England States; while in the Southern States they were employed for punishing slaves (*see* PILLORY).

STOCK-TAKING. To prepare a balance sheet (*q v.*) it is necessary for a trader to arrive at a valuation of his stock-in-trade; this process is called stock-taking or, in America, inventory-taking When proper stock records are available, they are of course an invaluable check upon the accuracy of the stock-taking; but in their absence it is essential that the process of stock-taking should be performed with the utmost care. If a wrong value be placed upon stock, the accounts embodying that valuation will to a corresponding extent mis-state the profits of the undertaking and its current financial position, and to a corresponding extent the accounts of the ensuing period will be affected in the opposite direction. The lower the rate of turnover the more serious will be any error in the periodical stock-taking. In many cases, the only independent check that the trader has upon the accuracy of his stock-taking is the inherent probability of the percentage of profit shown by the trading account.

The generally accepted basis for the correct valuation of stock-in-trade, assuming the goods to be in a readily saleable condition, is either the price they actually cost or the price at which they could then be bought in the open market, whichever of the two be the lower.

But although it is unsound to take into account any rise that there may have been in market values since the goods were bought, it would be equally unwise for a trader to dispose of his stock upon a rising market at normal prices, when he can only replace the goods sold at a greatly enhanced figure Usually, therefore, although rising market prices are ignored for stock-taking purposes, selling prices are advanced as buying prices increase; and this is equalized by the fact that as buying prices fall, it commonly becomes necessary for the trader to reduce his selling prices, though he still has stock purchased at the higher rate

Responsibility.—In most businesses it is usual to make the general manager responsible for the general accuracy of the stock-taking. The managers of departments are responsible to him, and the actual work is split up among the various employees, each of whom is held responsible for his section of the work. Those employed in counting, measuring or weighing goods are usually those familiar with the handling of these goods, and thus able to identify them as being correctly described. The cost prices are then entered on the list by clerks from actual invoices The managers decide what (if any) percentage is to be deducted from goods that are old-fashioned, or otherwise out of condition, and the remaining calculations are then completed in the office, after which the summary is certified by the general manager

The actual process of taking stock is often rendered more difficult and uncertain because it has to go on while trading operations are in full swing, and goods are accordingly constantly coming in and going out. It is very necessary to take precautions to ensure that no errors arise from this cause. For this reason some business houses prefer to close their premises during stock-taking, even although it means a corresponding loss of trade Further, it is important to see that the invoices relating to all goods which have in fact been included in stock are also included in the books as purchases, even although (as is sometimes the case) the actual invoices do not come to hand until later; conversely, invoices already to hand relating to goods in transit may, of course, be excluded from purchases.

When the trade is a seasonal one, it is usual to fix a date for stock-taking that comes between the two seasons, as it is naturally more convenient to take stock when the stock is at its lowest. In such cases it sometimes happens that deliveries of new season's goods have already been accepted, the invoices for which are "dated forward," *i.e.*, into the new accounting period. In such cases it seems admissible to exclude the value of these goods both from the purchases of the past period and also from the stock-taking. (L. R. D.)

STOCKTON, FRANCIS RICHARD (1834–1902), American writer, was born in Philadelphia (Pa.), April 5, 1834. On the completion of his high-school course Stockton studied wood engraving, but his tastes were so definitely literary that he soon turned to journalism. He contributed to various magazines and was on the editorial staff of *Hearth and Home*, the *Century Magazine* and *St. Nicholas*, of which he became assistant editor in 1873. About 1880 he gave up editorial work for independent authorship He died in Washington (D C), April 20, 1902.

Stockton's first published books were fanciful stories for children—*Ting-a-Ling-Stories* (1870), *Roundabout Rambles in Lands of Fact and Fancy* (1872), etc. In 1879 his reputation with older readers was established by his amusing and original *Rudder Grange* (1879), his best long work, although a series of sketches rather than a novel. His peculiar talent was for the short story; some of the best examples are the title-stories of the volumes *The Lady or the Tiger?* (1884), *The Christmas Wreck* (1886) and *The Bee Man of Orn* (1887) Effective also are the novelettes *The Casting Away of Mrs. Lecks and Mrs. Aleshine* (1886), and its sequel, *The Dusantes* (1888)

STOCKTON, a city of central California, U S A , at the head of tidewater on the San Joaquin river, 80 m. E of San Francisco, the county seat of San Joaquin county It is on the Pacific highway; has a municipal airport; and is served by the Santa Fe, the Southern Pacific, the Western Pacific, electric and beltline railways, by motor-coach and truck lines in all directions, and by river boats to San Francisco. Pop. (1920) 40,296 (77% native white); 1928 local estimate, 58,000. Stockton has a level site, not much above sea-level, surrounded by the fertile lands of the San Joaquin valley, which produce great crops of potatoes, onions, beans, corn, asparagus, grain, Tokay grapes and other fruits. Over 50 commercial crops are grown in the county, valued in 1927 at $52,000,-000 Dredging of a deep-water channel which will make the port accessible to 90% of all ocean-going vessels was under way in 1928 The aggregate factory output of Stockton in 1927 was valued at $38,000,000; bank debits in 1926 totalled $324,934,000; and the assessed valuation of property for 1927 was $65,563,796. Stockton is the seat of the College of the Pacific (Methodist Episcopal), the oldest incorporated educational institution of the State, chartered in 1851, located in Santa Clara until 1871, and in San Jose from 1871 to 1922

There was a small settlement here (called Tuleberg, and later New Albany) before the discovery of gold. With the coming of the first gold-seekers the importance of the site as an outfitting point for the mining country immediately became apparent A town was laid out in the spring of 1849 and named after Robert Field Stockton, who had been prominent in the events which secured California for the United States. In 1850 Stockton became the county seat and was chartered as a city.

STOCKTON-ON-TEES, town and port in County Durham, England, on the Tees, 5½ m. above its mouth, and on the L.N E.R., 236 m. N from London. Pop. (1921) 64,126. At Norton, 1 m. N. St. Mary's church, once collegiate, shows fine Norman work. The chief buildings are a town hall, borough-hall, exchange and public library. The quays are accessible to vessels drawing 22½ ft. at high water spring tides. Stockton grew up round the castle of the bishops of Durham, to whom the town belonged even before their purchase of the earldom of Sadberge. The castle was probably built between 1183 and 1214, and it is said that King John granted a charter in 1214 but of this, no traces remain Stockton was divided into two parts: the "town," governed by the bailiff of the bishop, and the borough, under a mayor and aldermen. The bishop's bailiff was also the keeper of the castle. The borough is first mentioned in 1283. It occurs again in a record of 1328, and in 1344. Bishop Hatfield's survey (1377–82) gives a list of tenants within the borough. In 1644 the parliamentary troops

besieged and captured the castle, which was dismantled in 1652.

STOCKYARDS are located at meat-packing centres for the purpose of receiving live stock which are to be used in a packing plant or sold to farmers for further feeding. At most points where there are two or more packing companies, there are stockyards known as public stockyards. Many packing companies, especially those which are located at country points, have private stockyards for their own use. The U.S. Department of Agriculture compiles and publishes records of live stock receipts, shipments, etc., at 67 public stockyards in all sections of the country. The largest of these stockyards are located at Chicago, Kansas City, Omaha, St. Louis and St. Paul. Any farmer who wishes to sell live stock may ship his animals to one of these markets, usually consigning his animals to a commission firm whose function it is to sell to a packer or a live stock feeder, when animals require further feeding to improve their quality. When the animals arrive at the stockyards, they are unloaded into pens where they are watered and fed and held until they are sold. The costs of feeding and handling and the fees to the commission firm are paid by the farmer. At public stockyards, these charges are prescribed by the U.S. Department of Agriculture. The packers located near the stockyards send live stock buyers each day to the stockyards to buy their day's requirements. The buyers ride among the pens, accompanied by representatives of the commission firms, and make their offers for the animals they want. In practice, every animal sent to market is purchased by someone a few hours or days after its arrival. Moreover, live stock are sold on a cash basis, so that the farmer receives his money almost immediately after the animals have been sold. Approximately 60,000,000 to 80,000,000 hogs, 14,000,000 cattle and 16,000,000 sheep and lambs are marketed in the average year by U.S. farmers. (E. B. W.)

STODDARD, RICHARD HENRY (1825–1903), American writer, was born in Hingham (Mass.), July 2, 1825. As a boy Henry Stoddard read whatever he could find, and wrote and revised conscientiously and continuously. The literati of New York were kind; and soon Stoddard was contributing frequently to magazines and saving up money enough to have his first book *Footprints* (1848) published. Nathaniel Hawthorne helped him to secure a position in the New York custom-house (1853–70). Later he was private secretary to Gen. George B. McClellan in the New York dock department (1870–73); city librarian of New York (1874–75); literary editor of the New York *World* (1860–70) and the *Mail and Express* (1880–1903); and editor of the *Aldine* (1869–74). He died in New York, May 12, 1903. Stoddard's poems are sincere, original and felicitous in form.

STOESSEL, ALBERT FREDERIC (1894–   ), American musician, was born at St. Louis (Mo.), on Oct. 11, 1894. He was educated at the Berlin Hochschule, making his début as violinist in that city with the Blüthner Orchestra. During the World War he took over the directorship of the A.E.F. bandmasters' school from its founder, Walter Damrosch and later (1921) succeeded Mr. Damrosch as conductor of the New York Oratorio Society. The same year he was made conductor of the New York Symphony Concerts at Chautauqua, New York. When the department of music of New York university was created (1923) Stoessel was appointed its head.

STOFFLET, JEAN NICOLAS (1751–1796), Vendéan general, was born at Lunéville, the son of a miller. Long a private soldier in a Swiss regiment in France, and afterwards game-keeper to the comte de Colbert-Maulevrier, he joined the Vendéans when they rose against the Revolution. He was appointed major-general of the royalist army, and in 1794 succeeded La Rochejaquelein as commander-in-chief. He accepted the treaty of La Jaunaie (May 2, 1795). But he again took arms in December 1795 on behalf of the count of Provence (the future Louis XVIII.), from whom he had received the rank of *maréchal-de-camp*. He was taken prisoner, condemned to death by a military commission, and shot at Angers on Feb. 23, 1796.

See General d'Andigné, *Mémoires*, edited by E. Biré (1900–01); C. Loyer, "Cholet sous la domination de Stofflet," in *L'Anjou historique*, vol. iii. (1902–03).

STOICHEIOMETRY, in chemistry, is a term which, strictly, denotes the determination of the proportions in which elements or compounds react with one another, and may be extended to include the determination of atomic and molecular weights (Gr. *τοιχεῖα*, fundamental parts or elements; *μέτρον*, measure). Actually, however, it is often used in the still broader sense covering the study of the physical properties of gases, liquids and solids; this aspect of the subject is dealt with in the article CHEMISTRY, *Physical*. The present article deals with the determination of molecular weights, the fundamental atomic weights being dealt with under that heading.

It is possible to determine with accuracy only the molecular weights of gases or vapours and of solids in solution. No method is known of determining the molecular weights of solids as such, although modern work on crystal structure (*see* CRYSTALLOGRAPHY) enables one to say how many simple molecules are packed together in one unit cell of the crystal. Similarly, no method is available for finding the molecular complexity of liquids with certainty, although several criteria are used for judging whether a liquid consists of simple or of complex molecules. Thus most of these criteria agree in assigning a complex structure, possibly $(H_2O)_2$ or $(H_2O)_3$, to liquid water, but none is capable of precisely fixing the degree of complexity; and most of them agree in giving the simple formula C_6H_6 to liquid benzene, *i.e.,* it has the same molecular weight as its vapour. On the other hand, some recent views on this question regard water as having a considerable *but variable* degree of complexity, and benzene as having a similar *but constant* degree. (For fuller discussion of the molecular weights of liquids, *see* the article ASSOCIATION.) The two more precise cases are now dealt with, namely, (1) gases and (2) dissolved solids.

Gases.—The generalization due to Avogadro—that equal volumes of gases under the same conditions of temperature and pressure contain equal numbers of molecules—may be stated in the form that the densities of gases are proportional to their molecular weights. If therefore the density of a gas relative to hydrogen or oxygen is determined, the molecular weight of the gas should follow by simple proportion, since that of oxygen is 32 (taken as standard) and that of hydrogen 2·0154. Avogadro's law, however, is not rigorously true, except under extremely low pressures, and it is necessary to correct the observed densities to what they would be if the gases were *ideal, i.e.,* if they showed no departure from Boyle's law. The principles underlying such corrections are briefly as follows.

P. A. Guye's Method.—According to Boyle's law, the product of the pressure and the volume of a gas is constant at any definite temperature, and, further, according to Gay Lussac's (or Charles's) law, this constant is directly proportional to the absolute temperature. Hence, $pv=RT$, where R is the so-called *gas constant*. J. D. van der Waals showed that, for representation of the actual behaviour of a gas, this ideal equation must be replaced by

$$\left(p+\frac{a}{v^2}\right)(v-b)=RT,$$

where a and b are constants for any one gas, but differ for different gases. Now a study of the behaviours of gases over a wide range of pressures has led to the assignment of appropriate values of a and b to each gas; hence, if v is the volume actually occupied by one gram-molecule of a gas at a pressure of 1 atmosphere and at a temperature $T°$ (usually 0° C is taken), and V is the volume which it would occupy under ideal conditions at the same temperature and pressure, then we have

$$1\times V=RT=\left(1+\frac{a}{v^2}\right)(v-b)$$

or

$$V=v\left(1-\frac{b}{v}+\frac{a}{v^2}\right)\text{ (approx.),}$$

so that the necessary correction can be applied from the known values of a and b.

D. Berthelot's Method.—It is known that the product pv for

a gas (except hydrogen) decreases slightly with increasing pressure until a pressure of several hundred atmospheres is reached. From a study of this decrease at low pressures it is possible to find what the relative densities of two gases would be at an infinitesimally low pressure, p_0. If v_1 and v_0 are the volumes of a gas at pressures of about 1 atmos. (p_1) and p_0 respectively; if

$$1-\frac{p_1 v_1}{p_0 v_0}=\alpha;$$

and if a' and v' are the corresponding values for the reference gas which has the same volume v_0 at p_0; then, assuming that Avogadro's law holds rigidly for the very low pressure p_0, we have

$$p_1 v_1=(1-\alpha)\,p_0 v_0=(1-\alpha)\,RT$$

and $$p_1 v_1'=(1-\alpha')\,p_0 v_0=(1-\alpha')RT$$

whence $$\frac{v_1}{v_1'}=\frac{1-\alpha}{1-\alpha'},$$

i.e., the ratio of the vapour densities at atmospheric pressure can be corrected to the ideal ratio.

Lord Rayleigh and D Berthelot applied corrections in the latter way to many gases Thus, E W. Morley had found the density of oxygen relative to hydrogen to be 15 90 at ordinary pressures; since the value of α for oxygen is 0 0009 and for hydrogen $-$0 0005, the corrected density becomes 15·88 (H=1), or 16 00 (H=1·0077) in the units now adopted (*See* ATOMIC WEIGHTS) Compound gases are dealt with similarly; thus T Batuecas (1925) corrected the densities of ethylene, nitrous oxide and nitric oxide by examination of their compressibilities (alteration of v, and hence of pv, with change in p), and hence obtained C_2H_4=24·015; N_2O=44 003; NO=30 006 P A Guye and E Moles, among others, have determined many molecular and atomic weights by similar methods

The principle indicated here is applicable to the determination of the molecular weight of any vaporizable substance, and it is not necessary to compare the vapour density directly with that of oxygen, for, from the "ideal" vapour density, it is only necessary to calculate the weight (in grams) which would occupy 22 41 litres (corresponding to 32 grams of oxygen) at 0° C and 760 mm. pressure in order to determine the molecular weight

The theory of solution permits the investigation of the molecular weights of substances which dissolve in water or some other solvent It is shown in SOLUTION that a solute lowers the freezing point and raises the boiling point of the solvent in a regular manner as long as dilute solutions are dealt with It has been shown that if one gram-molecule of a solute be dissolved in 100 grams of solvent then the boiling point is raised by $0\,02T^2/w$ (say D) degrees, where T is the absolute boiling point and w the latent heat of vaporization of the solvent; this constant is known as the *molecular rise of the boiling point*, and varies from solvent to solvent If we dissolve, say, m grams of a substance of molecular weight M in 100 grams of the solvent and observe the elevation in the boiling point, d, then M is given by $M=mD/d$ Similar considerations apply to the freezing points of solutions In this case $D=0\,02T^2/w$, where T is the absolute freezing point of the pure solvent and w the latent heat of solidification To apply these principles it is only necessary therefore to determine the freezing (or boiling) point of the solvent (of which a known weight is taken), add a known weight of the solute, allow it to dissolve and then notice the fall (or rise) in the freezing (or boiling) point, from which values, if the molecular depression (or elevation) be known, the molecular weight of the dissolved substance is readily calculated. The following are the molecular depressions and elevations (with, respectively, the freezing and boiling points in brackets) of the commoner solvents.

Molecular depressions· aniline (6°), 58 7; benzene (5·4°), 50·0; acetic acid (17·0°), 39·0; nitrobenzene (5·3°), 70·0; phenol (40°), 72; water (0°), 18·5.

Molecular elevations acetic acid (118·1°), 25·3; acetone (56°), 17 1; alcohol (78°), 11·7; ether (35°), 21·7; benzene (80°), 26·7; chloroform (61°), 35·9; pyridine (115°), 29 5; water (100°), 5·1.

Other methods are available for dissolved substances, *e.g.*, determination of osmotic pressure, lowering of vapour pressure, and diminution of solubility, but these are little used. It must be remembered, however, that the molecular weight of a solid in solution is only apparent, for it may be affected by a great variety of factors. Thus, electrolytic dissociation of the solid if a salt will give an abnormally low value; separation as mixed crystals (*see* CHEMISTRY, PHYSICAL) with the solvent will cause errors; any interaction with the solvent, such as formation of hydrates or "solvates," will affect the result; and equally important is the circumstance that the "ebullioscopic" and "cryoscopic" (boiling point and freezing point) methods just described become increasingly inexact with increasing concentration of the solute. (*See* SOLUTION.) (A. D. M)

STOICS, a school of philosophers founded at the close of the 4th century B C. by Zeno of Citium, and so called from the Stoa or painted corridor (στοὰ ποικίλη) on the north side of the market-place at Athens, which, after its restoration by Cimon, the celebrated painter Polygnotus had adorned with frescoes representing scenes from the Trojan War But, though it arose on Hellenic soil, from lectures delivered in a public place at Athens, the school is scarcely to be considered a product of purely Greek intellect, but rather as the firstfruits of that interaction between West and East which followed the conquests of Alexander. Hardly a single Stoic of eminence was a citizen of any city in the heart of Greece, unless we make Aristo of Chios, Cleanthes of Assus and Panaetius of Rhodes exceptions Such lands as Cyprus, Cilicia and Syria, such cities as Citium, Soli, Heraclea in Pontus, Sidon, Carthage, Seleucia on the Tigris, Apamea by the Orontes, furnished the school with its scholars and presidents; Tarsus, Rhodes and Alexandria became famous as its university towns. As the first founder was of Phoenician descent, so he drew most of his adherents from the countries which were the seat of Hellenistic (as distinct from Hellenic) civilization; nor did Stoicism achieve its crowning triumph until it was brought to Rome, where the grave earnestness of the national character could appreciate its doctrine, and where for two centuries or more it was the creed, if not the philosophy, of all the best Romans Properly therefore it stands in marked antithesis to that fairest growth of old Hellas, the Academy, which saw the Stoa rise and fall—the one the typical school of Greece and Greek intellect, the other of the Hellenized East, and, under the early Roman Empire, of the whole civilized world The transcendent genius of its author, the vitality and romantic fortunes of his doctrine, claim our warmest sympathies for Platonism But it should not be forgotten that for more than four centuries the tide ran all the other way. It was Stoicism, not Platonism, that filled men's imaginations and exerted the wider and more active influence upon the ancient world at some of the busiest and most important times in all history

The history of the Stoic school may conveniently be divided in the usual threefold manner· the old Stoa, the middle or transition period (Diogenes of Seleucia, Boethus of Sidon, Panaetius, Posidonius), and the later Stoicism of Roman times. By the old Stoa is meant the period (*c* 304–205 B C) down to the death of Chrysippus, the second founder; then was laid the foundation of theory, to which hardly anything of importance was afterwards added. Confined almost to Athens, the school made its way slowly among many rivals Aristo of Chios and Herillus of Carthage, Zeno's heterodox pupils, Persaeus, his favourite disciple and housemate, the poet Aratus, and Sphaerus, the adviser of the Spartan king Cleomenes, are noteworthy minor names; but the chief interest centres about Zeno, Cleanthes, Chrysippus, who in succession built up the wondrous system.

Zeno.—Zeno's residence at Athens fell at a time when the great movement which Socrates originated had spent itself in the second generation of his spiritual descendants. Neither Theophrastus at the Lyceum, nor Xenocrates and Polemo at the Academy, nor Stilpo, who was drawing crowds to hear him at Megara, could be said to have inherited much of the great reformer's intellectual vigour, to say nothing of his moral earnestness. Zeno visited all the schools in turn, but seems to have attached himself definitely to the Cynics; as a Cynic he composed at least one of his more important works, "the much admired *Republic*," which we know

to have been later on a stumbling-block to the school. In the Cynic school he found the practical spirit which he divined to be the great need of that stirring troublous age. For a while his motto must have been "back to Socrates," or at least "back to Antisthenes." The Stoics always counted themselves amongst the Socratic schools, and canonized Antisthenes and Diogenes; while reverence for Socrates was the tie which united to them such an accomplished writer upon lighter ethical topics as the versatile Persaeus, who, at the capital of Antigonus Gonatas, with hardly anything of the professional philosopher about him, reminds us of Xenophon, or even Prodicus. Zeno commenced, then, as a Cynic; and in the developed system we can point to a kernel of Cynic doctrine to which various philosophemes of other thinkers (more especially Heraclitus and Aristotle, but also Diogenes of Apollonia, the Pythagoreans, and the medical school of Hippocrates in a lesser degree) were added. Thus, quite apart from the general similarity of their ethical doctrine, the Cynics were materialists; they were also nominalists, and combated the Platonic ideas; in their theory of knowledge they made use of "reason" (λόγος), which was also one of their leading ethical conceptions. In all these particulars Zeno followed them, and the last is the more important, because, Chrysippus having adopted a new criterion of truth—a clear and distinct perception of sense—it is only from casual notices we learn that the elder Stoics had approximated to Cynicism in making right reason the standard. At the same time, it is certain that the main outlines of the characteristic physical doctrine, which is after all the foundation of their ethics and logic, were the work of Zeno. The Logos, which had been an ethical or psychological principle to the Cynics, received at his hands an extension throughout the natural world, in which Heraclitean influence is unmistakable.

Cleanthes.—If the recognition of physics and logic as two studies co-ordinate with ethics is sufficient to differentiate the mature Zeno from the Cynic author of the *Republic,* no less than from his own heterodox disciple Aristo, the elaboration on all sides of Stoic natural philosophy belongs to Cleanthes, who certainly was not the merely docile and receptive intelligence he is sometimes represented as being. He carried on and completed the assimilation of Heraclitean doctrine; but his own contributions were more distinctive and original than those of any other Stoic. He was able to transform Zeno's seeming dualism of God (or force) and formless matter into the lofty pantheism which breathes in every line of the famous hymn to Zeus. Heraclitus had indeed declared all to be in flux, but we ask in vain what is the cause for the unceasing process of his ever-living fire. It was left for Cleanthes to discover this motive cause in a conception familiar to Zeno, as to the Cynics before him, but restricted to the region of ethics—the conception of tension or effort. The soul of the sage, thought the Cynics, should be strained and braced for judgment and action; his first need is firmness (εὐτονία) and Socratic strength. But the mind is a corporeal thing. Then followed the flash of genius: this varying tension of the one substance everywhere present, a purely physical fact, accounts for the diverse destinies of all innumerable particular things; it is the veritable cause of the flux and process of the universe. Herein lies the key to the entire system of the Stoics, as Cleanthes's epoch-making discovery continually received fresh applications to physics, ethics and epistemology.

Chrysippus.—Zeno had caught the practical spirit of his age—the desire for a popular philosophy to meet individual needs. But there was another tendency in post-Aristotelian thought—to lean upon authority and substitute learning for independent research—which grew stronger just in proportion as the fresh interest in the problems of the universe and the zeal for discovery declined—a shadow, we may call it, of the coming Scholasticism thrown a thousand years in advance. The representative of this tendency, Chrysippus, addressed himself to the congenial task of assimilating, developing, systematizing the doctrines bequeathed to him, and, above all, securing them in their stereotyped and final form, not simply from the assaults of the past, but, as after a long and successful career of controversy and polemical authorship he fondly hoped, from all possible attack in the future. To his personal characteristics can be traced the hair-splitting and formal pedantry which ever afterwards marked the activity of the school, the dry repellent technical procedure of the Dialecticians *par excellence,* as they were called. He created their formal logic and contributed much that was of value to their psychology and epistemology; but in the main his work was to new-label and new-arrange in every department, and to lavish most care and attention on the least important parts—the logical terminology and the refutation of fallacies, or, as his opponents declared, the excogitation of fallacies which even he could not refute.

Stoic Conception of Philosophy.—What is philosophy? No idle gratification of curiosity, no theory divorced from practice, no pursuit of science for its own sake, but knowledge so far forth as it can be realized in virtuous action, the learning of virtue by exercise and effort and training. So absolutely is the "rare and priceless wisdom" identical with virtue itself that the three main divisions of philosophy current at the time and accepted by Zeno—logic, physics and ethics—are defined as the most generic or comprehensive *virtues.* Accordingly Aristo rejected two of these parts of philosophy as useless and out of reach—a divergence which excluded him from the school, but strictly consistent with his view that ethics alone is scientific knowledge. Of the three divisions logic is the least important; ethics is the outcome of the whole, and historically the all-important vital element; but the foundations of the whole system are best discerned in the science of nature, which deals pre-eminently with the macrocosm and the microcosm, the universe and man, including natural theology and anthropology or psychology, the latter forming the direct introduction to ethics.

Physics.—The Stoic system is in brief: (*a*) materialism, (*b*) dynamic materialism, lastly (*c*) monism or pantheism. (*a*) The first of these characters is described by anticipation in Plato's *Sophist* (246 C *seq.*), where, arguing with those "who drag everything down to the corporeal" (σῶμα), the Eleatic stranger would fain prove to them the existence of something incorporeal, as follows. "They admit the existence of an animate body. Is soul then something existent (οὐσία)? Yes. And the qualities of soul, as justice and wisdom—are they visible and tangible? No. Do they then exist? They are in a dilemma." Now, however effective against Plato's contemporary Cynics or Atomists, the reasoning is thrown away upon the Stoics, who take boldly the one horn of this dilemma. That qualities of bodies (and therefore of the corporeal soul) exist they do not deny; but they assert most uncompromisingly that they are one and all (wisdom, justice, etc.) corporeal. And they strengthen their position by taking Plato's own definition (247 D), namely "being is that which has the power to act or be acted upon," and turning it against him. For this is only true of Body; action, except by contact, is inconceivable; and they reduce every form of causation to the efficient cause, which implies the communication of motion from one body to another. Again and again, therefore, only Body exists. The most real realities to Plato and Aristotle had been thought and the objects of thought, νοῦς and νοητά, whether abstracted from sensibles or inherent in "matter," as the incognizable basis of all concrete existence. But this was too great an effort to last long. Such spiritualistic theories were nowhere really maintained after Aristotle and outside the circle of his immediate followers. The reaction came and left nothing of it all; for five centuries the dominant tone of the older and the newer schools alike was frankly materialistic. "If," says Aristotle, "there is no other substance but the organic substances of nature, physics will be the highest of the sciences," a conclusion which passed for axiomatic until the rise of Neoplatonism. The analogues therefore of metaphysical problems must be sought in physics; particularly that problem of the causes of things for which the Platonic idea and the Peripatetic "constitutive form" had been, each in its turn, received solutions. (*b*) But the doctrine that all existence is confined within the limits of the sensible universe—that there is no being save corporeal being or body—does not suffice to characterize the Stoic system; it is no less a doctrine of the Epicureans. It is the idea of tension or tonicity as the essential attribute of body, in contradistinction to passive inert matter, which

is distinctively Stoic The Epicureans leave unexplained the primary constitution and first movements of their atoms or elemental solids; chance or declination may account for them Now, to the Stoics nothing passes unexplained; there is a reason (λόγος) for everything in nature. Everything which exists is at once capable of acting and being acted upon. In everything that exists, therefore, even the smallest particle, there are these two principles. By virtue of the passive principle the thing is susceptible of motion and modification; it is matter which determines substance (οὐσία). The active principle makes the matter a given determinate thing, characterizing and qualifying it, whence it is termed quality (ποιότης). For all that is or happens there is an immediate cause or antecedent, and as "cause" means "cause of motion," and only body can act upon body, it follows that this antecedent cause is itself as truly corporeal as the matter upon which it acts. Thus we are led to regard the active principle "force" as everywhere coextensive with "matter," as pervading and permeating it, and together with it occupying and filling space. This is that famous doctrine of universal permeation (κρᾶσις δἰ ὅλου), by which the axiom that two bodies cannot occupy the same space is practically denied. Thus that harmony of separate doctrines which contributes to the impressive simplicity of the Stoic physics is only attained at the cost of offending healthy common sense, for Body itself is robbed of a characteristic attribute A thing is no longer, as Plato once thought, hot or hard or bright by partaking in abstract heat or hardness or brightness, but by containing within its own substance the material of these qualities, conceived as air-currents in various degrees of tension We hear, too, of corporeal days and years, corporeal virtues, and actions (like walking) which are bodies (σώματα). Obviously, again, the Stoic quality corresponds to Aristotle's essential form; in both systems the active principle, "the cause of all that matter becomes," is that which accounts for the existence of a given concrete thing (λόγος τῆς οὐσίας) Only here, instead of assuming something immaterial (and therefore unverifiable), we fall back upon a current of air or gas (πνεῦμα); the essential reason of the thing is itself material, standing to it in the relation of a gaseous to a solid body. Here, too, the reason of things—that which accounts for them—is no longer some external end to which they are tending; it is something acting within them, "a spirit deeply interfused," germinating and developing as from a seed in the heart of each separate thing that exists (λόγος σπερματικός). By its prompting the thing grows, develops and decays, while this "germinal reason," the element of quality in the thing, remains constant through all its changes

Psychology and Theory of Knowledge.—If, however, in the science of nature the Stoics can lay claim to no striking originality, the case is different when we come to the science of man. In the rational creatures—man and the gods—Pneuma is manifested in a high degree of purity and intensity as an emanation from the world-soul, itself an emanation from the primary substance of purest ether—a spark of the celestial fire, or, more accurately, fiery breath, which is a mean between fire and air, characterized by vital warmth more than by dryness. The physical basis of Stoic psychology deserves the closest attention. On the one hand, soul is corporeal, else it would have no real existence, would be incapable of extension in three dimensions (and therefore of equable diffusion all over the body), incapable of holding the body together, as the Stoics contended that it does, herein presenting a sharp contrast to the Epicurean tenet that it is the body which confines and shelters the light vagrant atoms of soul. On the other hand, this corporeal thing is veritably and identically reason, mind, and ruling principle (λόγος, νους, ἡγεμονικόν); in virtue of its divine origin Cleanthes can say to Zeus, "We too are thy offspring," and a Seneca can calmly insist that, if man and God are not on perfect equality, the superiority rests rather on our side. What God is for the world that the soul is for man. The Cosmos must be conceived as a single whole, its variety being referred to varying stages of condensation in Pneuma. So, too, the human soul must possess absolute simplicity, its varying functions being conditioned by the degrees or species of its tension. It follows that of "parts" of the soul, as previous thinkers imagined, there can be no question; all that can consistently be maintained is that from the centre of the body—the heart—seven distinct air-currents are discharged to various organs, which are so many modes of the one soul's activity. The ethical consequences of this position will be seen at a later stage. With this psychology is intimately connected the Stoic theory of knowledge. From the unity of soul it follows that all psychical processes—sensation, assent, impulse—proceed from reason, the ruling part; that is to say, there is no strife or division: the one rational soul alone has sensations, assents to judgments, is impelled towards objects of desire just as much as it thinks or reasons.

Cosmopolitanism.—In their view of man's social relations the Stoics are greatly in advance of preceding schools. We saw that virtue is a law which governs the universe: that which Reason and God ordain must be accepted as binding upon the particle of reason which is in each one of us. Human law comes into existence when men recognize this obligation; justice is therefore natural and not something merely conventional The opposite tendencies, to allow to the individual responsibility and freedom, and to demand of him obedience to law, are both features of the system; but in virtue even of the freedom which belongs to him *qua* rational, he must recognize the society of rational beings of which he is a member, and subordinate his own ends to the ends and needs of this society. Those who own one law are citizens of one state, the city of Zeus, in which men and gods have their dwelling In that city all is ordained by reason working intelligently, and the members exist for the sake of one another; there is an intimate connection (συμπάθεια) between them which makes all the wise and virtuous friends, even if personally unknown, and leads them to contribute to one another's good. Their intercourse should find expression in justice, in friendship, in family and political life But practically the Stoic philosopher always had some good excuse for withdrawing from the narrow political life of the city in which he found himself The circumstances of the time, such as the decay of Greek city-life, the foundation of large territorial states under absolute Greek rulers which followed upon Alexander's conquests, and afterwards the rise of the world-empire of Rome, aided to develop the leading idea of Zeno's *Republic* There he had anticipated a state without family life, without law courts or coins, without schools or temples, in which all differences of nationality would be merged in the common brotherhood of man. This cosmopolitan citizenship remained all through a distinctive Stoic dogma, when first announced it must have had a powerful influence upon the minds of men, diverting them from the distractions of almost parochial politics to a boundless vista. There was, then, no longer any difference between Greek and barbarian, between male and female, bond and free.

Religion.—The religious problem had peculiar interest for the school which discerned God everywhere as the ruler and upholder, and at the same time the law, of the world that He had evolved from Himself. The physical ground-work lends a religious sanction to all moral duties, and Cleanthes's noble hymn is evidence how far a system of natural religion could go in providing satisfaction for the cravings of the religious temper:—

"Most glorious of immortals, O Zeus of many names, almighty and everlasting, sovereign of nature, directing all in accordance with law, thee it is fitting that all mortals should address . . . Thee all this universe, as it rolls circling round the earth, obeys wheresoever thou dost guide, and gladly owns thy sway. Such a minister thou holdest in thy invincible hands—the two-edged, fiery, everliving thunderbolt, under whose stroke all nature shudders. No work upon earth is wrought apart from thee, lord, nor through the divine ethereal sphere, nor upon the sea; save only whatsoever deeds wicked men do in their own foolishness. Nay, thou knowest how to make even the rough smooth, and to bring order out of disorder; and things not friendly are friendly in thy sight. For so hast thou fitted all things together, the good with the evil, that there might be one eternal law over all. . . . Deliver men from fell ignorance. Banish it, father, from their soul, and grant them to obtain wisdom, whereon relying thou rulest all things with justice."

To the orthodox theology of Greece and Rome the system stood in a twofold relation, as criticism and rationalism. That the popular religion contained gross errors hardly needed to be

pointed out. The forms of worship were known to be trivial or mischievous, the myths unworthy or immoral. But Zeno declared images, shrines, temples, sacrifices, prayers and worship to be of no avail. A really acceptable prayer, he taught, can only have reference to a virtuous and devout mind: God is best worshipped in the shrine of the heart by the desire to know and obey Him. At the same time the Stoics felt at liberty to defend and uphold the truth in polytheism. Not only is the primitive substance God, the one supreme being, but divinity must be ascribed to His manifestations—to the heavenly bodies, which are conceived, like Plato's created gods, as the highest of rational beings, to the forces of nature, even to deified men; and thus the world was peopled with divine agencies. Moreover, the myths were rationalized and allegorized, which was not in either case an original procedure. The search for a deeper hidden meaning beside the literal one had been begun by Democritus, Empedocles, the Sophists and the Cynics. It remained for Zeno to carry this to a much greater extent and to seek out or invent "natural principles" (*λόγοι φυσικοί*) and moral ideas in all the legends and in the poetry of Homer and Hesiod. In this sense he was the pattern if not the "father" of all such as allegorize and reconcile.

Stoicism in Rome.—The introduction of Stoicism at Rome was the most momentous of the many changes that it saw. After the first sharp collision with the jealousy of the national authorities it found a ready acceptance, and made rapid progress amongst the noblest families. It has been well said that the old heroes of the republic were unconscious Stoics, fitted by their narrowness, their stern simplicity and devotion to duty for the almost Semitic earnestness of the new doctrine. In Greece its insensibility to art and the cultivation of life was a fatal defect; not so with the shrewd men of the world, desirous of qualifying as advocates or jurists. It supplied them with an incentive to scientific research in archaeology and grammar; it penetrated jurisprudence until the belief in the ultimate identity of the *jus gentium* with the law of nature modified the praetor's edicts for centuries. Even to the prosaic religion of old Rome, with its narrow original conception and multitude of burdensome rites, it became in some sort a support. Scaevola, following Panaetius, explained that the prudence of statesmen had established this public institution in the service of order midway between the errors of popular superstition and the barren truths of enlightened philosophy. Soon the influence of the pupils reacted upon the doctrines taught. Of speculative interest the ordinary Roman had as little as may be; for abstract discussion and controversy he cared nothing. Indifferent to the scientific basis or logical development of doctrines, he selected from various writers and from different schools what he found most serviceable. All had to be simplified and disengaged from technical subtleties. To attract his Roman pupils Panaetius would naturally choose simple topics susceptible of rhetorical treatment or of application to individual details. He was the representative, not merely of Stoicism, but of Greece and Greek literature, and would feel pride in introducing its greatest masterpieces: amongst all that he studied, he valued most the writings of Plato. He admired the classic style, the exquisite purity of language, the flights of imagination, but he admired above all the philosophy. He marks a reaction of the genuine Hellenic spirit against the austerity of the first Stoics.

The Later Stoics.—The writings of the later Stoics have come down to us, if not entire, in great part, so that Seneca, Cornutus, Persius, Lucan, Epictetus, Marcus Aurelius are known at first hand. They do not profess to give a scientific exposition of doctrine, and may therefore be dismissed somewhat briefly (*see* EPICTETUS and MARCUS AURELIUS). We learn much more about the Stoic system from the scanty fragments of the first founders, or even from the epitomes of Diogenes Laërtius and Stobaeus, than from these writers. They testify to the restriction of philosophy to the practical side, and to the increasing tendency, ever since Panaetius, towards a relaxation of the rigorous ethical doctrine and its approximation to the form of religious conviction. This finds most marked expression in the doctrines of submission to Providence and universal philanthropy. Only in this way could they hold their ground, however insecurely, in face of the religious reaction of the 1st century. In passing to Rome, Stoicism quitted the school for actual life. The fall of the republic was a gain, for it released so much intellectual activity from civic duties. The life and death of Cato fired the imagination of a degenerate age in which he stood out both as a Roman and a Stoic. To a long line of illustrious successors, men like Thrasea Paetus and Helvidius Priscus, Cato bequeathed his resolute opposition to the dominant power of the times; unsympathetic, impracticable, but fearless in demeanour, they were a standing reproach to the corruption and tyranny of their age. But when at first, under Augustus, the empire restored order, philosophy became bolder and addressed every class in society, public lectures and spiritual direction being the two forms in which it mainly showed activity. Books of direction were written by Sextius in Greek (as afterwards by Seneca in Latin), almost the only Roman who had the ambition to found a sect, though in ethics he mainly followed Stoicism. His contemporary Papirius Fabianus was the popular lecturer of that day, producing a powerful effect by his denunciations of the manners of the time. Under Tiberius, Sotion and Attalus were attended by crowds of hearers.

Seneca.—Seneca is the most prominent leader in the direction which Roman Stoicism now took. His penetrating intellect had mastered the subtleties of the system of Chrysippus, but they seldom appear in his works, at least without, apology. Incidentally we meet there with the doctrines of Pneuma and of tension, of the corporeal nature of the virtues and the affections, and much more to the same effect. But his attention is claimed for physics chiefly as a means of elevating the mind, and as making known the wisdom of Providence and the moral government of the world. To reconcile the ways of God to man had been the ambition of Chrysippus, as we know from Plutarch's criticisms. He argued plausibly that natural evil was a thing indifferent—that even moral evil was required in the divine economy as a foil to set off good. The really difficult problem why the prosperity of the wicked and the calamity of the just were permitted under the divine government he met in various ways: sometimes he alleged the forgetfulness of higher powers; sometimes he fell back upon the necessity of these contrasts and grotesque passages in the comedy of human life. Seneca gives the true Stoic answer in his treatise *On Providence:* the wise man cannot really meet with misfortune; all outward calamity is a divine instrument of training, designed to exercise his powers and teach the world the indifference of external conditions. In the soul Seneca recognizes an effluence of the divine spirit, a god in the human frame; in virtue of this he maintains the essential dignity and internal freedom of man in every human being. Yet, in striking contrast to this orthodox tenet is his vivid conception of the weakness and misery of men, the hopelessness of the struggle with evil, whether in society or in the individual. Thus he describes the body (which, after Epicurus, he calls the flesh) as a mere husk or fetter or prison of the soul; with its departure begins the soul's true life. Sometimes, too, he writes as if he accepted an irrational as well as a rational part of the soul. In ethics, if there is no novelty of doctrine, there is a surprising change in the mode of its application. The ideal sage has receded; philosophy comes as a physician, not to the whole but to the sick. We learn that there are various classes of patients in "progress" (*προκοπή*), *i.e.*, on their way to virtue, making painful efforts towards it. The first stage is the eradication of vicious habits: evil tendencies are to be corrected, and a guard kept on the corrupt propensities of the reason. Suppose this achieved, we have yet to struggle with single attacks of the passions: irascibility may be cured, but we may succumb to a fit of rage. To achieve this second stage the impulses must be trained in such a way that the fitness of things indifferent may be the guide of conduct. Even then it remains to give the will that property of rigid infallibility without which we are always liable to err, and this must be effected by the training of the judgment. Other peculiarities of the later Stoic ethics are due to the condition of the times. In a time of moral corruption and oppressive rule, as the early empire repeatedly became to the privileged classes of Roman society, a general feeling of insecurity led the student of philosophy to seek in it a refuge against the vicissi-

tudes of fortune which he daily beheld.

Musonius.—From Seneca we turn, not without satisfaction, to men of sterner mould, such as Musonius Rufus, who certainly deserves a place beside his more illustrious disciple, Epictetus. As a teacher he commanded universal respect, and wherever we catch a glimpse of his activity he appears to advantage. His philosophy, however, is yet more concentrated upon practice than Seneca's, and in ethics he is almost at the position of Aristo. Epictetus testifies to the powerful hold he acquired upon his pupils, each of whom felt that Musonius spoke to his heart.

Epictetus.—In the life and teaching of Epictetus this thought bore abundant fruit. The beautiful character which rose superior to weakness, poverty and slave's estate is also presented to us in the *Discourses* of his disciple Arrian as a model of religious resignation, of forbearance and love towards our brethren, that is, towards all men, since God is our common father. With him even the "physical basis" of ethics takes the form of a religious dogma—the providence of God and the perfection of the world. We learn that he regards the δαίμων or "guardian angel" as the divine part in each man; sometimes it is more nearly conscience, at other times reason. His ethics, too, have a religious character. He begins with human weakness and man's need of God: whoso would become good must first be convinced that he is evil Submission is enforced by an argument which almost amounts to a retractation of the difference between things natural and things contrary to nature, as understood by Zeno. Would you be cut off from the universe? he asks. Go to, grow healthy and rich. But if not, if you are a part of it, then be resigned to your lot.

Aurelius.—Epictetus is marked out amongst Stoics by his renunciation of the world. He is followed by a Stoic emperor, M. Aurelius Antoninus, who, though in the world, was not of it. The *Meditations* give no systematic exposition of belief, but there are many indications of the religious spirit we have already observed, together with an almost Platonic psychology. Following Epictetus, he speaks of man as a corpse bearing about a soul; at another time he has a threefold division—(1) body, (2) soul, the seat of impulse (πνευμάτιον), and (3) νοῦς or intelligence, the proper *ego*. In all he writes there is a vein of sadness: the flux of all things, the vanity of life, are thoughts which perpetually recur, along with resignation to the will of God and forbearance towards others, and the religious longing to be rid of the burden and to depart to God. These peculiarities in M. Antoninus may perhaps be explained in harmony with the older Stoic teaching; but, when taken in connection with the rise of Neoplatonism and the revival of superstition, they are certainly significant. None of the ancient systems fell so rapidly as the Stoa It had just touched the highest point of practical morality, and in a generation after M. Antoninus there is hardly a professor to be named. Its most valuable lessons to the world were preserved in Christianity; but the grand simplicity of its monism slumbered for fifteen centuries before it was revived by Spinoza.

STOKE NEWINGTON, a borough of London, England. Pop. (1921) 52,172; area 863 acres. In Church Street is the ancient parish church of St Mary, largely restored. The borough returns one member to Parliament.

STOKE-ON-TRENT, a city in Staffordshire, England, in the heart of the Potteries Pop (1921) 240,428. Stoke-upon-Trent, Burslem, Fenton, Hanley, Longton and Tunstall were amalgamated on March 31, 1910. In 1925 the borough became a city. The principal public buildings are the town hall (enlarged 1910–12), the county court offices, the market hall, the Minton memorial building, the Victoria institute (Tunstall), the central library and branch libraries, the central school of science and technology, secondary schools, etc. There are several large parks within the city boundaries. In addition to the potteries, there are coal-mines, as well as deposits of coarse clay, but the finer china-clay comes from Cornwall and elsewhere. New industries, *e.g.*, electrical accessories, rubber tyre manufacture, dyeing, etc., are also prosperous. The district is well served by railways and also by the Grand Trunk (Trent and Mersey) canal. There is a statue to Josiah Wedgwood (b. 1730) in Burslem. Other names made famous by the pottery industry here are, Josiah Spode (b. 1754), Herbert Minton (b. 1793) and the Copelands.

In the Domesday Survey of 1086 half the church of Stoke and lands in Stoca are said to have belonged to Robert of Stafford. Market rights were not acquired until 1845. By the Reform Bill (1832) Stoke sent two members to parliament, and since 1918, three members. It was first incorporated in 1874

STOKE POGES, a village in Buckinghamshire, England. The church of St. Giles has portions of Norman, Early English, and later dates, and Thomas Gray is buried in the churchyard, held to be the original of his *Elegy.* The manor-house finds mention in his *Long Story* West End Cottage, where he often stayed, remains in altered form as Stoke Court Burnham Beeches, a favourite haunt of Gray's, is about 3 mi. away.

STOKES, ADRIAN (1887–1927), English bacteriologist, was born at Lausanne, and educated at Trinity college, Dublin, becoming demonstrator in anatomy, and assistant professor of pathology. During the World War, he established a mobile laboratory for the prevention of epidemic outbreaks, including typhoid His inoculation of the Belgian civil population helped to suppress enteric. He was awarded the Belgian order of the Crown, and in 1918 received the D S O. After the war (1919) he became professor at Dublin and in 1922 he was appointed to the Sir William Dunn chair of pathology. In 1920 the Rockefeller Commission on Yellow Fever in West Africa included Stokes among its members, and in 1927 asked him to go out to West Africa. He collaborated with Hideyo Noguchi (*q.v*) and William Young, and their discovery of a monkey susceptible to the disease enabled them to prepare a preventive vaccine. Stokes became infected with the disease, and died on Sept 19, 1927 He published papers, particularly on infectious jaundice, typhoid carriers and dysentery.

STOKES, SIR (FREDERICK) WILFRID SCOTT K.B.E. (1860–1927), engineer and inventor, son of Scott Nasmyth Stokes, was born in 1860 at Liverpool After some years in railway work he joined Ransomes and Rapier of Ipswich, becoming managing director and chairman. He was distinguished in many branches of engineering. His inventions, for which some fifty patents were granted, included improvements in sluice gates, breakdown cranes, railway, hydraulic, refrigerating and cement making machinery, ordnance and projectiles. He had a share in many notable engineering achievements at home and abroad, including the Manchester ship canal and the irrigation works in India, Egypt and the Sudan. He was responsible for the design of the sluice and lock gates, and he was present both at the opening of the Assuan dam 1901 and of the Sennar dam 1926.

From 1915 until 1918 Stokes served on Ministry of Munitions inventions committees, and he was also chairman of the East Anglian and other munitions committees. In 1915 he acquired fame by the timely invention of the Stokes trench mortar and ammunition (*see* TRENCH ORDNANCE and MUNITIONS OF WAR). At great personal risk and without previous technical knowledge of explosives he perfected the shells of which more than twenty million rounds were used with deadly effect in the trenches and at Zeebrugge and elsewhere. He also promoted the invention of effective anti-aircraft shells. For his public services he was created K.B.E. in 1917. Stokes was president of the British Engineers' Association 1916–1918.

Desert (1927); W. Stokes, "Sluices and Lock Gates of the Nile Reservoir, Assuan," *Proc. Inst. Civil Engineers* (1902–03); "The Stokes Gun and Shell and their development," *Engineering*, June 28, 1918, "The Sennar Dam," *Engineering*, Jan. 22, 1926, "The late Sir W. Stokes," *Engineering*, Feb. 11, 1927; "The Stokes Gun," *Whitehall Gazette*, Oct. 1919; "Sir W. Stokes," *The Engineer*, Feb. 11, 1927.

STOKES, SIR GEORGE GABRIEL, Bart. (1819–1903), British mathematician and physicist, son of the rector of Skreen, Co. Sligo, Ireland, was born on Aug. 13, 1819. In 1837 he entered Pembroke college, Cambridge, where he became a fellow in 1841. He lost his fellowship when he married in 1857, but twelve years later, under new statutes, he was re-elected. In 1902, he was elected Master. As Lucasian professor, secretary and president of the Royal Society, he held three offices, which had only once before been held by one man, Sir Isaac Newton. He was member of parliament for the University from 1887 to 1892, was created baronet in 1889 and died on Feb. 1, 1903.

Stokes was the oldest of the trio of physicists, Clerk Maxwell and Lord Kelvin being the other two, who especially contributed to the fame of the Cambridge school of mathematical physics in the middle of the 19th century. The Royal Society's catalogue of scientific papers gives the titles of over a hundred memoirs by him published down to 1883. The greater part of his work was concerned with waves and the transformations imposed on them during their passage through various media. His first published papers, which appeared in 1842 and 1843, were on the steady motion of incompressible fluids and some cases of fluid motion; these were followed in 1845 by one on the friction of fluids in motion and the equilibrium and motion of elastic solids, and in 1850 by another on the effects of the internal friction of fluids on the motion of pendulums. To the theory of sound he made several contributions, including a discussion of the effect of wind on the intensity of sound and an explanation of how the intensity is influenced by the nature of the gas in which the sound is produced. These inquiries together put the science of hydrodynamics on a new footing, and provided a key not only to the explanation of many natural phenomena, such as the suspension of clouds in air, and the subsidence of ripples and waves in water, but also to the solution of practical problems, such as the flow of water in rivers and channels, and the skin resistance of ships.

His best-known researches are perhaps those on the undulatory theory of light. His first papers on the aberration of light appeared in 1845 and 1846, and were followed in 1848 by one on the theory of certain bands seen in the spectrum. In 1849 his paper on the dynamical theory of diffraction showed that the plane of polarization must be perpendicular to the direction of vibration. Two years later he discussed the colours of thick plates; and in 1852, in his famous paper on the change of refrangibility of light, he described the phenomenon of fluorescence, as exhibited by fluorspar and uranium glass, materials which he viewed as having the power to convert invisible ultra-violet rays into rays of wave lengths which are visible. A mechanical model, illustrating the dynamical principle of Stokes's explanation was shown in 1883, during a lecture at the Royal Institution, by Lord Kelvin, who said he had heard an account of it from Stokes many years before, and had repeatedly but vainly begged him to publish it. In the same year, 1852, there appeared the paper on the composition and resolution of streams of polarized light from different sources, and in 1853 an investigation of the metallic reflection exhibited by certain non-metallic substances. About 1860 he was engaged in an inquiry on the intensity of light reflected from, or transmitted through, a pile of plates; and in 1862 he prepared for the British Association a valuable report on double refraction, which marks a period in the history of the subject in England. A paper on the long spectrum of the electric light bears the same date, and was followed by an inquiry into the absorption spectrum of blood.

The discrimination of organic bodies by their optical properties was treated in 1864; and later, in conjunction with the Rev. W. Vernon Harcourt, he investigated the relation between the chemical constitution and the optical properties of various glasses, with reference to the conditions of transparency and the improvement of achromatic telescopes. A still later paper connected with the construction of optical instruments discussed the theoretical limits to the aperture of microscopical objectives. In other departments of physics may be mentioned his paper on the conduction of heat in crystals (1851) and his inquiries in connection with the radiometer; his explanation of the light border frequently noticed in photographs just outside the outline of a dark body seen against the sky (1883); and, still later, his theory of the Röntgen rays, which he suggested might be transverse waves travelling as innumerable solitary waves, not in regular trains. Two long papers published in 1849—one on attractions and Clairaut's theorem, and the other on the variation of gravity at the surface of the earth—also demand notice, as do his mathematical memoirs on the critical values of the sums of periodic series (1847) and on the numerical calculation of a class of definite integrals and infinite series (1850) and his valuable discussion of a differential equation relating to the strains, stresses and other factors involved in the breaking of railway bridges (1849).

Many of his discoveries were only touched upon in lectures. An instance is his work in the theory of spectrum analysis. Some of Stokes's friends and pupils claimed that he had anticipated Kirchhoff but Stokes maintained that he had failed to see an essential step in the argument and disclaimed priority. As Lucasian professor, Stokes announced that he wished to help any member of the university in his mathematical studies, and pupils were glad to consult him, even after they had become colleagues. During the thirty years of his secretaryship to the Royal Society he advanced the cause of mathematical and physical science, not only by his own investigations, but by suggesting problems for inquiry and inciting men to attack them.

He received the Rumford medal in 1852 and in 1893, the Copley medal. His numerous other honours included the Prussian Ordre pour le Mérite. In 1869 he presided over the Exeter meeting of the British Association.

Sir George Stokes's mathematical and physical papers were published in a collected form in five volumes; the first three (Cambridge, 1880, 1883, and 1901) under his own editorship, and the two last (Cambridge, 1904 and 1905) under that of Sir Joseph Larmor, who also selected and arranged the *Memoir and Scientific Correspondence* of Stokes published at Cambridge in 1907. Stokes was the author of *Light* (1884–87) and *Natural Theology* (1891).

STOKES, WHITLEY (1830–1909), British lawyer and Celtic scholar, was a son of William Stokes (1804–1878), and a grandson of Whitley Stokes (1763–1845), each of whom was regius professor of physic in the university of Dublin. Educated at Trinity college, Dublin, young Stokes became a barrister and in 1862 went out to India. In 1877 he became legal member of the viceroy's council, and he drafted the codes of civil and criminal procedure. After his return to England in 1882 he devoted himself to the Celtic studies which made him famous. He studied Irish, Breton and Cornish texts, and among his numerous works may be mentioned editions of *Three Irish Glossaries* (1862); *Three Middle-Irish Homilies* (1877); and *Old Irish Glosses at Würzburg and Carlsruhe* (1887). He was one of the editors of the *Irische Texte* published at Leipzig (1880–1900); and he edited and translated *Lives of Saints from the Book of Lismore* (1890). With Professor A. Bezzenberger he wrote *Urkeltischer Sprachschatz* (1894). His principal legal work was *The Anglo-Indian Codes* (1887). He died in London, April 13, 1909.

STOKESAY, a parish and hamlet in Shropshire, England, 6½ m. N.W. of Ludlow, with an interesting old church and one of the most remarkable moated manor houses surviving in Britain. Its north tower, of stone, belongs to the early 12th century, and a timber structure was placed on it about 1620–30, when a timbered building and a half-timbered gate-house were built. The banqueting hall and solar date from 1240 and the south tower from 1291. The solar was re-decorated in 1665. There have been modern repairs.

STOLBERG, FRIEDRICH LEOPOLD, Graf zu (1750–1819), German poet, the younger son of Count Christian Stolberg, was born at Bramstedt in Holstein on Nov. 7, 1750. He studied in Göttingen and was a member of the famous Göttinger *Hain* or *Dichterbund*. After leaving the university he made a journey to Switzerland with his brother Christian, in company with

Goethe. In 1777 he was appointed envoy of the prince bishop of Lübeck at the court of Copenhagen, but often stayed at Eutin, where he was the intimate associate of J. H. Voss. In 1782 he married Agnes von Witzleben, whom he celebrated in his poems After her early death in 1788, he became Danish envoy at the court of Berlin, and contracted a second marriage with the countess Sophie von Redern in 1789. In 1791 he was appointed president of the Lubeck episcopal court at Eutin; he resigned this office in 1800, and retiring to Münster in Westphalia, there joined, with his whole family, the eldest daughter only excepted, the Roman Catholic Church. For this step he was severely attacked by his former friend Voss (*Wie ward Fritz Stolberg ein Unfreier?* 1819). After living for a while (from 1812) in the neighbourhood of Bielefeld, he removed to his estate of Sondermuhlen near Osnabruck, where he died on Dec 5, 1819. He wrote many odes, ballads, satires and dramas—among the last the tragedy *Timoleon* (1784), translations of the *Iliad* (1778), of Plato (1796–1797), Aeschylus (1802), and Ossian (1806); he published in 1815, a *Leben Alfreds des Grossen*, and a voluminous *Geschichte der Religion Jesu Christi* (17 vols., 1806–1818).

Stolberg's brother, CHRISTIAN, GRAF ZU STOLBERG (1748–1821), was also a poet Born at Hamburg on Oct. 15, 1748, he became a magistrate at Tremsbuttel in Holstein in 1777, and died on Jan 18, 1821. Of the two brothers Friedrich was undoubtedly the more talented, but Christian, though not a poet of high originality, excelled in the utterance of gentle sentiment They published together a volume of poems, *Gedichte* (edited by H C. Boie, 1779); *Schauspiele mit Choren* (1787), their object in the latter work being to revive a love for the Greek drama; and a collection of patriotic poems *Vaterlandische Gedichte* (1815) Christian von Stolberg was the sole author of *Gedichte aus dem Griechischen* (1782), a translation of the works of Sophocles (1787), and of a poem in seven ballads, *Die weisse Frau* (1814), which last attained considerable popularity

The Collected Works of Christian and Friedrich Leopold zu Stolberg were published in twenty volumes in 1820–25, 2nd ed. 1827 Friedrich's correspondence with F. H Jacobi will be found in Jacobi's *Briefwechsel* (1825–27), that with Voss has been edited by O Hellinghaus (1891) Selections from the poetry of the two brothers will be found in A Sauer's *Der Gottinger Dichterbund*, iii (Kurschner's *Deutsche Nationallitteratur*, vol 50, 1896). *See* also T. Menge, *Der Graf F. L Stolberg und seine Zeitgenossen* (2 vols., 1862), J. H. Hennes, *Aus F. L von Stolbergs Jugendjahren* (1876); the same, *Stolberg in den zwei letzten Jahrzehnten seines Lebens* (1875); J. Janssen, *F L Graf zu Stolberg* (2 vols, 1877), 2nd ed 1882; W Keiper, *F. L Stolbergs Jugendpoesie* (1893).

STOLBERG, a town in the Prussian Rhine province. Pop (1925) 17,096. Its prosperity was founded in the 17th century by French refugees, who introduced brass-founding. A castle is on the site of a church said to have been used by Charlemagne. The leading industry is metal-working in zinc, brass and iron

STOLE, a liturgical vestment of the Catholic Church, peculiar to the higher orders, *i e*, deacons, priests and bishops It is a strip of stuff, usually silk, some 2½yds. long by 4in broad, in the middle and at the ends, which are commonly broadened out, it is ornamented with a cross. Its colour varies with the liturgical colour of the day, or of the function at which it is worn.

The stole is worn immediately over the alb or surplice, by deacons, scarfwise over the left shoulder, across the breast and back to the right side; by priests and bishops, dependent from the neck, the two ends falling over the breast. In the case of bishops the stole always hangs straight down; while priests wear it crossed over the breast when vested in the alb According to the Roman usage the stole is now only worn at Mass

The origin of the stole is very obscure It has been variously derived from the ancient *stola,* which was, however, a tunic, from the Jewish prayer-blanket (*tallith*), from the ancient *orarion* (neck-cloth) and, as regards the diaconal stole, from a napkin used in the liturgy Father Braun, however, in his *Liturgische Gewandung,* gives good reasons for rejecting all these derivations and suggests that the stole was originally introduced as that which first appears in the 22nd canon of Laodicea, viz, a special mark of distinction for deacons, which was later extended to higher orders.

The stole was not one of the vestments prescribed by the rubrics of the first Prayer-book of Edward VI. (*see* VESTMENTS). It was replaced in the Church of England from the Reformation onwards by the scarf, a broad band of black silk, formerly part of the outdoor dress of the dignified clergy and without liturgical significance. This vestment has some resemblance to the stole, in that it is worn round the neck, hanging straight down in front over each shoulder. This resemblance facilitated the reintroduction of the stole by the "Ritualists" during the 19th century. The revised Prayer-book, adopted by Convocation and the Church Assembly in 1927, authorizes the use of the "stole or scarf."

STOLEN GOODS: *see* LARCENY

STOLP, a town in Pomerania. Pop. (1925) 41,826 Stolp received town rights in 1273. From the 14th to the 16th century it was a member of the Hanseatic League Until 1637, when it passed to Brandenburg, the town usually belonged to the dukes of Pomerania. The large church of St. Mary, with a 14th century tower, the 16th century Renaissance castle, now used as a prison, one of the ancient town-gates restored in 1872 and the church of St. John (13th century) are the oldest buildings.

STOLYPIN, PETER ARCADIEVICH (1863–1911), Russian statesman, was born at Baden-Baden in 1863 He was educated at St. Petersburg (Leningrad), and in 1902 he became governor of Grodno, and in 1903 of Saratov, where he was a firm administrator In 1906 he was minister of internal affairs, and in July succeeded Goremykin as minister-president (*See* RUSSIA) His relentless policy led to attempts upon his life In Aug 1906 a bomb was exploded at his summer residence, injuring a daughter, and on Sept 14, 1911, he was shot in a theatre at Kiev before the eyes of the Imperial family, by a Jew, Mordka Bogrov He died on Sept. 18, 1911.

STOMACH, the bag-like digestive organ which in man is situated in the upper left part of the abdomen. For anatomical details *see* ALIMENTARY CANAL For the diseases of the stomach in general *see* DIGESTIVE ORGANS, and for special forms, GASTRITIS, GASTRIC ULCER, DYSPEPSIA, etc, also ABDOMEN.

STONE, EDWARD JAMES (1831–1897), British astronomer, was born in London on Feb 28, 1831 He was educated at the City of London School, King's College, London, and Queen's College, Cambridge In 1860 he succeeded Main as chief assistant at the Royal Observatory, Greenwich He deduced the solar parallax, first from observations of Mars, obtaining 8·932″ (*Mon. Not R A S* xxiii 183), and 8·945″ (*Mem. of R A S*, vol xxxiii), and secondly from the transit of Venus in 1769 which yielded 8 91″ (*Mon Not R.A S* xxviii 255). From the Greenwich transit circle observations between 1851 and 1865 he found for the constant of lunar nutation the value 9 134″. He received the Royal Astronomical Society's gold medal in 1869, and in 1870 became astronomer at the Cape

He produced a catalogue of 12,441 stars to the 7th magnitude between the South Pole and 25° S declination, published as the *Cape Catalogue* for 1880 In 1878, he was appointed Radcliffe Observer at Oxford. At Oxford he extended the Cape observations of stars to the 7th magnitude from 25° S declination to the equator, and collected the results in the *Radcliffe Catalogue* for 1890, which contains the places of 6,424 stars Stone observed the transit of Venus of 1874 at the Cape, and organized similar expeditions in 1882. He was president of the Royal Astronomical Society (1882–1884), and drew attention to the old observations at the Radcliffe Observatory by Hornsby, Robertson and Rigaud (*Mon Not. R A S*, vol. lv.). He died at Oxford on May 9, 1897.

STONE, GEORGE (1708–1764), archbishop of Armagh, the son of a London banker, was educated at Westminster school and Christ Church, Oxford. He took holy orders, and advanced rapidly in the Church, mainly through the influence of his brother Andrew (1703–1773), who was under-secretary of State (1834) under George II. and treasurer to Queen Charlotte under George III. When the duke of Dorset became lord-lieutenant of Ireland (1731), George Stone went to Ireland as his chaplain. After holding various preferments in Ireland as dean and bishop, he became archbishop of Armagh in 1747. As archbishop he proved more a politician than an ecclesiastic. In 1758 Stone wrote a letter, preserved in the *Bedford Correspondence* (ii. 357), in which he speaks despondently of the distress of the people. He was one of the "undertakers" who controlled the Irish House of Commons, and took a prominent share in the administration of Ireland until his death in London on Dec. 19, 1764.

Although this "much-abused prelate," as Lecky calls him, was a firm supporter of the English Government in Ireland, he was not intolerant. It was due to him that the anti-tithe disturbances in Ulster in 1763 were suppressed with little bloodshed; he favoured conciliation towards the Roman Catholics, whose loyalty he defended.

STONE, LUCY (Blackwell) (1818–1893), American reformer, anti-slavery and woman's-rights leader, was born in West Brookfield, Mass., Aug. 13, 1818. Her father refused her the college education that she so eagerly desired, but she earned enough to carry her through Oberlin college, where she graduated in 1847. She immediately went on the lecture platform as an advocate of abolition and of woman's rights, and her remarkable voice and commanding eloquence often held in check the most disorderly audiences. In 1855 she married Dr. Henry B. Blackwell (1824–1909), a prominent abolitionist and advocate of woman's rights, who agreed that she should keep her maiden name; after 1870 he assisted his wife in the management of the *Woman's Journal* of Boston of which she became editor in 1872.

She allowed her New Jersey property to be sold for taxes, and then published a pamphlet on "taxation without representation." She campaigned for woman's suffrage amendments in Kansas (1867), Vermont (1870), Michigan (1874), Colorado (1877) and Nebraska (1892). She died in Dorchester, Oct. 18, 1893.

STONE, MELVILLE ELIJAH (1848–1929), American journalist, was born in Hudson (Ill.), Aug. 22, 1848. In 1860 his father was made pastor of a Methodist church in Chicago, and it was there that he got his schooling. In 1864 he began as a reporter for the Chicago *Tribune*, but he became proprietor in 1869 of an iron-foundry and machine shop. In the great Chicago fire of 1871 this was destroyed, and Stone then engaged in the administrative work of municipal relief and reconstruction. In 1872 he became one of the editors of the Chicago *Republican* (subsequently *Inter-Ocean*), and later of the *Post and Mail*, becoming for several years a political correspondent at Washington.

At the end of 1875, having returned to Chicago, Stone, with a colleague, started the evening *Daily News*, and two years later Victor F. Lawson became a partner. The venture was very prosperous. He and Lawson bought out the *Post and Mail*, and in 1881 they established the *Morning News* (later *Record* and *Record-Herald*). In 1888 he retired, and later founded the Globe National Bank, of which he became president in 1892. In 1893 he became general manager of the Associated Press, which received a new stimulus. He held this position until April 1921. During that 28 years the budget of the Associated Press had grown from $500,000 to $6,000,000, and it had come to furnish more than half the news printed in American papers. He died in New York city on Feb. 15, 1929.

See his autobiography, *Fifty Years a Journalist* (1921).

STONE, NICHOLAS (1587–1647), English sculptor and architect, was the son of a quarryman of Woodbury, near Exeter, and as a boy was apprenticed to Isaac James, a London mason. About 1603 he went to Holland and worked under the sculptor Hendrik de Keyser (1567–1621) and his son Pieter, and married his master's daughter. Stone is said to have made the portico to the Westerkerk at Amsterdam. Returning to London about 1613 with Bernard Janssens (*fl.* 1610–1630), a fellow pupil, he settled in Southwark and obtained a large practice; in 1619 he was appointed master-mason to James I., and in 1626 to Charles I. He died in London on Aug. 24, 1647. Stone, whose work is associated with Inigo Jones's introduction of Renaissance architecture into England, ranks as the great sculptor of his time and the rejuvenator of the art in England.

See an article by A. E. Bullock in the *Architectural Review*, 1907, and the same author's illustrated monograph *Some Sculptural Works of Nicholas Stone* (Batsford, London, 1908).

STONE, market town, urban district, Stone parliamentary division, Staffordshire, England. Pop. (1921) 5,552. There are remains of an abbey (670) here; the abbey church collapsed in 1749 and on the site, St. Michael's church was built (1750). Alleyne's grammar school is a foundation of 1558. There is an ancient earthwork at Bury Bank and others at Saxon Low.

STONE, a detached piece or fragment of rock. The word is thus applied to the small fragments scattered in the ground or on roads, to the water-worn pebbles of the sea-shore or river beds, and to the hewn, dressed or shaped rock used as building material, with which this article deals. A qualifying word generally accompanies "stone" when the term is applied to pieces of rock cut to a particular size and shape and used for a specific purpose, *e.g.*, "mill-stone," "hearth-stone," "grave-stone," etc. The term "precious stone" is used of those minerals which, from their beauty of colour, etc., their rarity and sometimes their hardness, are valued for their suitability for ornaments (*see* Gems). The word is also often applied to many objects resembling a stone or pebble, such as the hard kernel of certain fruits, as of the cherry, plum, peach, etc., or the *calculi* or concretions sometimes formed in the gall or urinary bladder or the kidneys. (*See* Bladder Diseases and Kidney Diseases.) The "stone" has been a common measure of weight in north-western Europe. In Germany the "Stein" was of 20 to 22 lbs. In the British system of weights the "legal" stone, or "horseman's" weight is of 14 lb. avoirdupois; in weighing wool it was also of 14 lb., but is now usually 16 lb. The "customary" stone for fish or butcher's meat is of eight pounds.

Building Stone.—Stone selected for building purposes must be strong enough to bear the load placed upon it, it must be durable and weather well in the atmosphere of the district, and its colour and appearance need to be studied. Available supply and price are factors. Where there is risk of fire, as in factories, the stone must be resistant to heat.

The disintegration of stone is caused by internal stresses. They may be set up, as in the case of granite, by heat, which causes the quartz or silica constituent to change its chemical form with an accompanying expansion. Similarly quartz or silica pebbles used as an aggregate in concrete cause its disintegration when subjected to extreme heat. Again the internal stresses may be set up by the solution and recrystallization of minerals, or chemical substances, in the pores of the stone, for all stone is more or less porous. In cold climates certain porous stones may be comparatively rapidly destroyed by alternate freezing and thawing—the mere expansion of the absorbed water in freezing being sufficient. Certain argillaceous limestones contain an earthy or clayey mineral now known as beidellite which has the property of absorbing or possibly chemically combining with water. This is accompanied by expansion, and causes apparently sound stone to rapidly disintegrate when exposed to the weather. Smoke and waste gases from heating and industrial plants are carried by rain into the pores of the stone. Marbles and limestone, being composed largely of the carbonates of lime and magnesia, are very susceptible to the solvent action of these acids. The mortar used to bed the stones has been held responsible for disintegration since the lime may be dissolved out by the action of rain water, to be recrystallized in the interior pores of the adjacent stone. The physical and chemical tests for stone are thus as follows:

(1) Resistance to crushing; (2) acid test; (3) absorption test; (4) microscopical examination; (5) freezing and thawing test or its equivalent.

The resistance to crushing varies to an enormous extent with the different kinds of stone, from a little over 60 tons per sq.ft.,

which is the limit for a weak limestone, up to a load of over 1,300 tons necessary to crush the hardest granites. In general practice the load placed upon stone should not exceed one-tenth of the crushing weight as found by testing. The effect produced by soaking pieces of stone for some days in a 1% solution of sulphuric and hydrochloric acids will decide roughly whether it will be durable in a city atmosphere. The microscope is the best means of determining the structure of a stone, and of recognizing the presence of matter likely to affect its usefulness adversely. Should iron pyrites be discovered in any quantity the stone should be rejected, as this impurity easily decomposes on exposure, and stains and splits the stone. The freezing and thawing test is slow and requires a rather elaborate refrigerating apparatus The specimens of stone to be tested are alternately oven-dried, soaked in water and subjected to a freezing temperature, thawed at room temperature, dried, and the cycle repeated as often as desired. The accumulative loss in weight of the dried sample after each cycle is the measure of the stone's durability or resistance. This test may be simulated with some degree of accuracy by the sodium-sulphate test, in which the specimens of stone are oven-dried, soaked in a saturated solution of sodium sulphate and allowed to dry out at room temperature. In drying out the sodium sulphate crystallizes in the pores of the stone, in a manner similar to the freezing or crystallizing of water. This test is apparently more severe than the freezing and thawing test and requires little apparatus Laboratory experts have not yet agreed upon the exact relation of these tests to the actual behaviour, or life, of stone in structures. Dolomites, known to be fairly durable as building stone, are not correspondingly resistant to these tests.

The hardest, least absorbent, and most compact and uniform stones are of ancient geological formation, and with time and increase of superimposed pressure have become dense and very hard. The softer stones are of later formation, and are usually lighter in weight and more porous A good stone should ring clearly when struck with steel, and a fresh fracture should on examination be bright, clean and sharp in texture and free from loose grains. A dull earthy appearance indicates an inferior stone.

The most usual method adopted for preserving stonework is to paint the exposed surfaces with ordinary oil colour. The painting must be redone every four or five years *Boiled linseed oil* is sometimes used on stonework, one or more coats being well brushed in after cleaning it. Its use deepens the colour of the stone, and unless very carefully done the work is apt to appear patchy. A large number of processes consist of coating the stonework with a solution of soluble silica. In *Kuhlmann's process* a solution of silicate of potash or soda is brushed into the stone and, aided by the carbonic acid in the air, acts upon some of the constituents of the stone and forms a hard surface which is not liable to decay. In *Ransome's process,* a solution of silicate of soda is applied until the surface of the stone has become saturated This is allowed to dry and a solution of chloride of calcium is then applied in a similar manner. The two solutions act together, and by decomposition produce an insoluble silicate of lime which fills the pores of the stone and binds its particles together thereby checking decay. *Baryta water* will, when applied to limestone that has decayed owing to the action of sulphurous fumes, penetrate into and solidify the crumbling portions, with the result that the stone is reconstituted and becomes hard and quite solid. Prof A H. Church employed this method in arresting the decay of the frescoes in the Houses of Parliament and the stonework of the chapter house at Westminster was also treated by him in the same manner *Fluate* is the name given to a siliceous preservative specially recommended for use upon the limestones from the Bath district. It may also be applied to other limestones, and to bricks, tiles, terra-cotta, etc. It does not materially change the appearance of the stone but enters the pores and prevents decay.

The natural bed of a stone is that surface on which it was originally deposited. But volcanic and other disturbances may have occurred since that time and completely altered its "lie"; and therefore it frequently happens that a horizontal line does not coincide with the natural bed of stone as it rests in the quarry. Care must be taken before using the stone to find the proper bed and to set all stones with their laminae quite level. Stone fresh from the quarry is found to contain a quantity of moisture called "quarry sap," on account of which all stones (even granite) are comparatively soft when first quarried This water gradually evaporates, and after some months' exposure stones that were quite soft and weak when quarried acquire hardness and strength. For these reasons it is desirable from an economical point of view to "work" the stone to its desired shape and mould and carve it when soft and easily workable

Varieties of Stone.—Building-stones are divided into several groups; limestones and sandstones are classified as aqueous or stratified rock granite being igneous or unstratified.

Limestones consist chiefly of calcium carbonate with small proportions of other substances. They are often classified under four heads: *Compact* limestones consist of carbonate of lime, either pure or in combination with clay and sand. *Granular* or *oolitic* limestones consist of grains of carbonate of lime cemented together by the same substance or mixed with sand and clay. The grains are egg-shaped (hence the name "oolite") and vary in size from tiny particles to grains as large as peas *Shelly* limestones consist almost entirely of small shells, cemented together by carbonate of lime *Magnesian* limestones are composed of carbonates of lime and magnesia in varying proportions, and usually also contain small quantities of silica, iron and alumina Stones having less than 15% of magnesia are not classed under this head *Dolomites* are limestones containing equal proportions of carbonate of lime and carbonate of magnesia Many of the finest building-stones are limestones In England typical examples are the Bath stones, Portland stone and Kentish ragstone, and in America those from the States of New York, Indiana (Bedford quarry, light brown stone), Illinois (Grafton and Chester quarries) and Kentucky (Bowling Green stone, light grey, similar to Portland). Notable French limestones are obtained from the quarries at Peuren (cream), Château-Gaillard (white), Abrots, Normandoux (white), and Villars (light brown) The hardest and closest grained of these are capable of taking a fine polish Limestones should be used with care as they are uncertain in their behaviour and usually more difficult to work than sandstones, and as a general rule they do not stand the action of fire well On being treated with a dilute acid, limestones will effervesce and by this test they can easily be identified. Limestones weigh between 130 lb. and 166 lb per cu ft. They vary in colour but most of them are cream or yellowish brown *Marble* is a limestone which has been changed by the action of heat and pressure into a crystalline form Many beautiful varieties are found which are suitable for interior decoration, such as for columns, wall lining, paving, etc , and in dry sunny climates they may be employed with great effect in external situations They will take a high polish and the fine grained varieties are well adapted for intricate carving The principal European supplies of marble are from Italy, Belgium and France, but the marbles from Ireland and those from Devonshire and Derbyshire possess a remarkable range of colour and variety of markings. America has few notable coloured marbles; most of the stones quarried are white or black. The States of Vermont (West Rutland and Sutherland Falls quarries), Tennessee and Georgia produce large quantities of marble *Marezzo* and *scagliola* are plaster imitations of marbles (*see* PLASTERWORK)

Sandstones are composed of grains of sand held together by a cementing substance to form a compact rock. The cementing medium may be silica, alumina, carbonate of lime or an oxide of iron. Those stones that have a siliceous cement are the most durable Sandstones vary more in colour than limestones, the colour being largely due to the presence of iron. Cream, brown, grey, pink, red, light and dark blue, and drab are common colours Typical British sandstones are Corsehill (red) from Dumfriesshire, the Yorkshire sandstones (brown), Pennant stone and Forest of Dean (blue and grey) from Gloucestershire. In America sandstones are quarried in many States, principally Connecticut (brown stone), New York (Potsdam red stone), Ohio (Amherst, Berea and other quarries, light brown or grey stone) and Massachusetts (Longmeadow brown stone). The heaviest, densest, least porous and most lasting stones usually have a fine grain

Granites are igneous rocks formed by volcanic action and are of all geological ages. Granite is composed of quartz, felspar and mica. Stones with a large proportion of quartz are hard and difficult to work. Earthy felspar is opaque and liable to decay; it should be almost transparent. The colour of the granite is generally due to this substance, but may be affected by the mica, whether light or dark. Granite is the hardest, strongest, and most durable of building-stones. When polished, many varieties present a beautiful and lasting surface. They are used for foundations, bases, columns, curbs and paving where strength is required.

The granites from Peterhead and Aberdeen in Scotland and from Cornwall and Devonshire in England are much used. In the United States good granites are quarried in Connecticut, Massachusetts and Minnesota. Canada, especially the eastern provinces, supplies excellent granite. So do Norway and Sweden. *Syenitic granite* contains hornblende in addition to quartz, felspar and mica. In true syenite hornblende takes the place of mica. It is named from a stone found at Syene in Egypt, but it has since been discovered that this stone actually contains more mica than hornblende. These rocks are very hard and are used more for paving and road-metalling than for building purposes.

Slate is composed of sandy clay metamorphosed by heat and pressure. Such rocks began as sediment by the sea or river. Owing to some sliding motion having taken place, slaty rocks can be split into thin sheets. A good slate will give out a metallic ring if struck, and when trimmed will not splinter. Slates range in colour from purple to grey and green. The best known British slates are those of the Welsh and Westmorland quarries. In America good slate is found in the States of New York, Pennsylvania and Maine. (*See* also ROOFS.)

There are several kinds of artificial stone on the market, consisting of fine cement concrete placed to set in wooden or iron moulds. Although from an artistic point of view it must be used with great discretion, it is prepared with such care that its cheapness, strength and uniform character have led to its wide employment. One of the best-known varieties is composed of finely crushed granite and Portland cement, carefully mixed by machinery in the proportions of three to one, and filled into moulds of the required shape. When the blocks are set hard the moulds are loosened and the blocks placed in a solution of silicate of soda for about two weeks for the purpose of indurating and hardening them. Many manufacturers turn out a material that is practically non-porous and is able effectually to resist the corroding influence of sea air or the impure atmosphere of large towns. Artificial stone is exceedingly useful for paving purposes, and blocks can readily be cast of any size or thickness to suit the pavements of streets or buildings; their regularity greatly reduces labour costs in laying.

See Rivington's *Notes on Building Construction* vol. iii.; also *Report on Building Stone for Extension of United States Capitol* (1849); J. L. Pearson, *Report of Select Committee on Westminster Hall* (Restoration) (1884–85); G. H. Blagrove, *Marble Decoration* (1888); F. E. Kidder, *Building Construction and Superintendence*, vol. i. (1896); G. P. Merril, *Stones for Building and Decoration* (1897). (J. BT.)

STONE AGE: *see* ARCHAEOLOGY.

STONE CARVING. Many as are the kinds, there is a character that properly belongs to all good stone carving, whether in relief (high relief or low) or in the round. The first constituent of this character is the quality called plasticity; it is the quality of solidity, of being in three dimensions. The beauty of stone carving is dependent upon this quality. Modelling in clay is a business wherein one starts from nothing, or perhaps a wire only (the "armature") and builds up a thing in three dimensions. But in a stone carving one does not start from nothing and build up; one starts from a solid thing and proceeds by subtraction instead of addition and, apart from the sensuous enjoyment which some people have in using tools and materials, the natural tendency in stone carving is to subtract as little as possible, as in modelling it is to add as little as possible. The result is that whereas a certain spareness and tensity of form is characteristic of modelling, the character most noticeable in stone carving is fullness and roundness of form—solidity, mass, weight. Moreover, by the use of wire or iron armatures it is possible to give a clay model any required freedom and detachment of parts—if it be an image of a man, the arms and legs may stand out freely from the body, fingers may be separate, and hair may even stand on end. In stone, on the other hand, freedom or detachment of parts is unnatural and difficult. The custom of many sculptors, ancient and modern, to work exclusively in clay and to leave the business of carving to hired mechanicians is responsible for the lack of the proper character of stone carving in their works. Trained mechanics are clever enough to do anything; whether the thing done be worth doing is not their affair.

In a stone carving done according to the natural character of stone, there is no detachment of parts; everything is solidly joined to everything else. If there be any separation between one thing and another the space between is in the nature of a hole—a piercing—as in the characteristic Byzantine foliage carving or in mediaeval window tracery. Stone is a brittle and very heavy material; it will stand enormous crushing strains but will hardly bend. These differing characters of materials render them suitable for different services—iron or wood for a girder subjected to a bending strain, stone for a pier or pillar, bronze for a gate, stone for a gate-post. And as each material renders its characteristic service, so each has its characteristic beauty. To imitate the characteristic beauty of flesh and blood in a material so different as stone is absurd in proportion to the success with which it is achieved; and it is as wasteful as it is ridiculous. The stick-beetle has excellent reasons for wishing to remain anonymous; that a stone carver should desire to produce illusions is folly. Moreover, it cannot be done, and the dust and dirt which collect in the veins and dimples of a realistic sculpture very soon betray it. The imitation of one material in another is wasteful because it is throwing away the special beauty of the material used. There is great beauty in the sculpture of Michelangelo, but it is not the beauty of stone.

The movement of the human mind which is called the Renaissance ushered in an entirely new attitude on the part of artists. Men who had formerly been part of the ordinary gang of builders, who made buildings or sculptures in stone or bronze as one makes boots or books in leather or skins, now ceased to be makers and became critics. They ceased to be, as they formerly were, men imitating nature by working as she works (*Ars imitetur naturam in sua operatione*. St. Thomas Aquinas, *Summa Theol. I.*, 9. 117, a. 1); they became men imitating nature by reproducing her appearance. The sculptor became a critic of nature, *pro* or *con*, and his works represented his view of the matter; they reflected nature and they reflected the artist and this not by accident, as hitherto, but of set purpose and to the applause of beholders. The results, admirable as we may think them and admirable as many of them are, have the characteristic beauty of human thought but not that of stone. The state of things which we call pre-Renaissance is the normal state of things in the world and is still the prevalent state in all places not affected by humanism. In mediaeval Europe, as in India or Japan, the idea of verisimilitude was either unknown or despised. Portraiture was non-existent, drawing from nature was not done at all or was confined to the merest "studies." In fact, pre-Renaissance work was "natural" precisely as a tree is natural or as an unornamented electrical switch-board is natural. The only difference between a tree and a stone carving was that the tree was the immediate product of unconscious natural causes whereas the stone carving was the product of a conscious and deliberating mind. Neither in the one case nor the other was there any more criticism or imitation of nature than is displayed in an electrical switch-board. It is only in the paucity of language that a sculptor would speak of carving a man or a flower. The likeness to nature is an accident of such works, not the substance. A crucifix of the 12th century, for instance, or a Buddha of the same date in India is not substantively a life-like imitation of a man as seen in flesh and blood. The substance of such things is their philosophical or religious significance. That being so, the artist was free to use or exploit the aesthetic possibilities of the material used to the fullest extent. Thus it is that for the study of stone carvings as works of art we are compelled to look to the past or to foreign and distant countries.

There is no question whether modern European stone or marble carvings are good or bad things. The statue of Gladstone in Westminster Abbey is probably an excellent portrait; it would simply be wrong to judge it as stone carving On the other hand, the sculptures of Egypt, India and China, like those of early mediaeval Europe, are primarily stone carvings; it would be wrong to judge them as portraits or as imitations of nature. After about 1350 the desire for verisimilitude became the ruling motive.

Generally, we may say a good stone carving is one which will not break (Michelangelo is said to have enunciated, but perhaps not followed, the dictum that the test of a good sculpture was that you could roll it down hill without breaking it); that stands firmly and well balanced; that is free from naturalistic modelling and undercutting; and in general we may say, paraphrasing the saying of Maurice Denis, "What we ask of stone carving is that it shall look like stone."

STONECHAT, a well-known British bird, *Saxicola torquata* The black head, ruddy breast, and white collar and wing spot of the cock, render him a conspicuous object on almost every furze-grown common or heath in the British Isles The stonechat is a small bird allied to the wheatear (*q.v.*) and whinchat (*q.v.*). It has a wide range in Europe and Asia; allied species inhabit Africa and Asia.

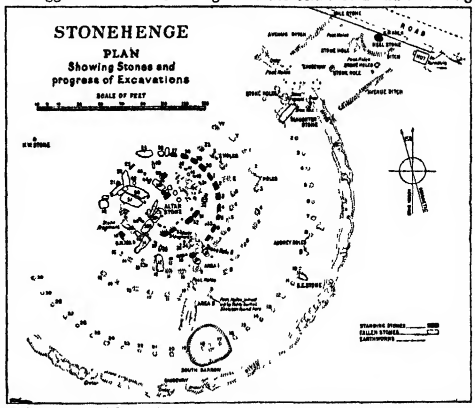
STONE-FLY, the name given to a small but well-defined group of insects forming the order Plecoptera (*q v.*) or Perlaria. They are found only in the vicinity of fresh water.

STONEHAM, a town of Middlesex county, Massachusetts, U.S.A. Pop. (1920) 7,873 (82% native white), 1928 local estimate 10,000. Within its area of 6·6. sq m. is Spot pond, a large lake which serves as a storage basin for the metropolitan water district; and 730 ac. of the Middlesex Fells Reservation. The manufactures include shoes, shoe stock, cutting dies, chemicals and druggists' supplies. Steam power was first applied to the manufacture of shoes here, by John Hill and Company, who introduced many labour-saving devices, notably the heeling machine (1862). Stoneham was settled about 1668. It was set off from Charlestown and incorporated as a town in 1725.

STONEHAVEN (locally *Stanehive*), seaport of Kincardineshire, Scotland Pop. (1921), 4,856. The town is picturesquely situated on the Carron. On the decay of Kincardine, the original capital, Stonehaven became the county town in 1600, and suffered heavily during the covenanting troubles, Montrose setting it on fire in 1645.

STONEHENGE, a circular group of huge standing stones (*see* STONE MONUMENTS) situated on Salisbury Plain, Wiltshire, England, about 7 m. N. of Salisbury. The amenities of this, the most important antiquity in the British Isles, have recently been marred by the erection of bungalows, aerodromes and tea-houses But now, thanks to the activities of The Stonehenge Preservation Committee (1927), an undertaking is near completion (1928) for purchasing and vesting in the National Trust the land for about a mile radius round Stonehenge, and the work of demolishing the buildings is in hand. In 1915 Sir Edmund Antrobus sold Stonehenge to Sir Cecil Chubb, who generously presented it to the nation, and since that date it has been under the charge of H M Office of Works. Professor Gowland in 1901 restored to a vertical position the leaning upright (No. 56) of the great inner trilithon, and in 1919 and 1920 H M. Office of Works re-erected uprights 29, 30, 1 and 2 securing lintels.

Neither Roman historian nor Saxon chronicler makes mention of Stonehenge. Perhaps the earliest reference to it is in the writings of Henry of Huntingdon (died 1154), who cites Stonehenge as the second of the four wonders of England, but confesses ignorance of its origin Geoffrey of Monmouth relates in his *Historia Britonum* (written before 1139) that Ambrosius Aurelianus, desirous of setting up a memorial to those slain in the battle with Hengist in 470, by the advice and with the aid of the magical powers of Merlin, removed the stones of The Giants' Dance from Kildare, Ireland, whither, according to Giraldus Cambrensis, they had been brought from Africa by giants, and re-erected them on the site of Stonehenge. This legend with slight alterations was current until Edmund Bolton in 1624 made the suggestion that Stonehenge was the tomb of Boudicca. Inigo



FROM THE ANTIQUARIES JOURNAL BY COURTESY OF THE SOCIETY OF ANTIQUARIES AND OF H M OFFICE OF WORKS

Jones in his treatise on Stonehenge, written at the command of James I. and published in 1655, timidly puts forward the suggestion that Stonehenge was built by the Druids, but goes on to state with more emphasis that it is a Roman temple inscribed to Coelus. In opposition to this, Dr. Charleton, a court physician, propounded the theory in 1663 that Stonehenge was the work of Danes. It was John Aubrey (1626–1697) who first claimed Stonehenge as a Druidical temple, and this theory was elaborated by William Stukeley in 1742. Thus originated a belief which up to the present day has found favour with the public, although there is no evidence to support it. As late as 1872 James Fergusson contended that Stonehenge was a sepulchral monument of the Saxon period.

Stonehenge is approached by an ancient banked trackway, the so-called Avenue, on the north-east. As viewed to-day, it consists of an encircling earthwork and the remains of four series of stones, viz.: an outer circle of sarsens with lintels; an inner bluestone circle; a horse-shoe of five great sarsen trilithons; and an inner ovoid of bluestones. There are also two sarsen stones lying north-west and south-east of the circle close to the inner edge of the earthwork; a recumbent slab of sarsen, the so-called Slaughter Stone, near the south-east edge of the north-eastern causeway in the ditch; an upright sarsen, the Hele Stone, situated in the Avenue; and a recumbent block of micaceous sandstone, known as the Altar Stone, within the bluestone ovoid. The outer circle has a diameter of 100·75 ft, and consists of thirty large upright sarsens, carefully dressed into shape by pounding with stone mauls, of which sixteen remain standing. Their average height above ground is 13½ ft., depth below ground 4½ ft. and weight 26 tons. Their flat sides face inwards and they are secured by means of sarsen lintels, each lintel dovetailing with its fellow, and a mortice at each end of every lintel fitting over one of the two conical tenons on each upright. The inner circle of bluestones has a diameter of 76½ ft. To-day nine of the stones are standing, while eleven are overthrown. Recent excavations by the Society of Antiquaries of London have shown that the original number of stones in this circle exceeded the previously estimated number of forty. The five great sarsen trilithons are arranged in a horse-shoe with the opening to the north-east, and rise gradually in height towards the south-west. Only two are standing to-day. The height above ground of the great upright (No. 56), raised and made secure in 1901, is 22 ft. The inner ovoid con-

PRESENT–DAY STONE CARVING

1. A stone carver equipped with pneumatic chisel, finishing the stars on the collar of General Robert E. Lee, the leading figure in the heroic group designed by Augustus Lukeman for the Stone Mountain Memorial near Atlanta, Georgia

2. Carving with mallet and chisel a portion of the head of General Robert E. Lee, 400 feet up the side of Stone Mountain near Atlanta, Georgia. When completed, this group may be seen for several miles. It is larger and more elaborate than the colossal Ramessean figures of Abu Simbel hewn in the rock cliffs on the banks of the Nile

sisted of dressed bluestones, of which twelve are visible now. The original number is uncertain, but excavation has proved that the series formed an ovoid and not a horse-shoe as was formerly supposed. The bluestones now remaining are of two varieties—diabase and rhyolite, but fragments of basic tuffs and agglomerates, grey wackes and argillaceous flagstones and slates may have belonged to stones now missing.

In the past Stonehenge has been a battleground on which archaeologists have fought with assumptions as their only weapons, but within recent years careful and systematic excavation, if it has not furnished definite evidence as to the purpose and date of construction of the monument, has at least added considerably to our knowledge.

The Avenue, first described in 1723 by Stukeley, approaches Stonehenge on the north-east, but its banks do not coincide with the sides of the causeway across the ditch which encircles Stonehenge. This suggests that it is a more recent structure. It consists of a broad road with lateral ditches and a slight bank between road and ditch. From Stonehenge it runs a straight course for 1,700 ft. in a north-easterly direction. Then, according to Stukeley, it branches, one arm curving westwards to meet the Cursus, the other "directly east, pointing to an ancient ford of the river Avon." In 1921, by the aid of photographs from the air, Crawford was able to trace the continuation of the Avenue from its furthest fixed point on the ridge between the Old and New King Barrows to the Stonehenge-Amesbury road opposite West Amesbury Farm. These photographs were verified by excavation, and excavation has since traced the Avenue across the road to the farm buildings, but there are no indications either on the surface or on air-photographs that it was continued across the river. The air-photographs also tend to disprove the existence of a western branch. At its Stonehenge end the Avenue measures 72 ft. from ditch to ditch, but as it progresses it varies in width, and measures 110½ ft. at West Amesbury.

Col. Hawley during his excavations for the Society of Antiquaries (1920–26) uncovered the eastern half of the ditch surrounding Stonehenge, and cleared the north-eastern causeway, which was found to be studded with postholes. He also discovered a smaller southern causeway (Inigo Jones mentioned three causeways, forming an equilateral triangle). The ditch is circular with a diameter of 300 ft., flat-bottomed, irregular, averages 5 ft. in depth, and has a bank on its inner side. The only objects found in its silting have been abundant red-deer antler picks, a few rough flint implements of Upper Palaeolithic facies, and two fragments of pottery. The chips of sarsen and bluestone struck off when the stones were dressed and set in place, are restricted to the lower level of the turf mould above the chalk silting.

In all, Col. Hawley cleared that half of the area inside the ditch which lies east of a north and south diameter. He discovered three important new features: a circle of holes parallel with and close inside the ditch and named by him Aubrey Holes, in honour of John Aubrey who recorded certain depressions along this line; and two new circles of holes, Z and Y, nearer to but still outside the outer sarsen circle. There are probably fifty-six Aubrey Holes, of which number thirty have been excavated. They are circular in plan, and average 3 ft. 8 in. in diameter and 2 ft. 8½ in. in depth. A small amount of cremated human bones was found in most of them, usually in a small pocket by the side of the hole. Sarsen and bluestone chips were present throughout their filling, but evidence is lacking as to whether stones or posts once stood in them. The Z and Y holes were wedge-shaped with rectangular bottoms. The Y holes averaged 2 ft. 11½ in. in depth and 5 ft. 6½ in. by 3 ft. 9 in. at the top. The Z holes averaged 3 ft. 6 in. in depth and 5 ft. 10½ in. by 3 ft. 8 in. at the top. They were constructed after the erection of the outer sarsen circle, but in all probability no stone or post ever stood in them. The Hele Stone was found to have an encircling ditch, with postholes to the west of it and three other stone holes between it and Stonehenge. The Slaughter Stone had been buried in its present position and no doubt once stood upright in a hole to the west of it. The isolated sarsen on the south-east just inside the ditch had no encircling ditch. The so-called "barrow" on the south in the line of the Aubrey Holes was not a barrow, but the site of an upright stone with encircling ditch. Between this "barrow" and the stone circles were numerous postholes, and within the circles the ground was honeycombed with others. Some were as old as, or older than, the erection of Stonehenge, but the date of most of them is as uncertain as is their purpose.

Stonehenge, as we see it to-day, is probably contemporary with the Avenue and is a reconstructed Stonehenge; an earlier and more simple circle of sarsens, contemporary with the ditch, having preceded it. The blocks of sarsen, Tertiary sandstone, were obtained from the Marlborough Downs; for sarsens in the immediate neighbourhood were scanty and small of size. The bluestones were brought from Prescelly in Pembrokeshire—a locality rich in stone circles. Two theories as to the purpose of Stonehenge exist to-day, the sun-worship theory and the sepulchral. The former was promulgated by Sir Norman Lockyer in 1901, but for many reasons, too many to recapitulate here, is probably erroneous, and the sepulchral theory is more likely to be the correct one. But all is surmise and analogy our only guide. Stonehenge is a stone circle, albeit an elaborate one, and most of those stone circles that have been carefully excavated have been proved to be sepulchral. With regard to the date of erection of the present Stonehenge, we have also to rely chiefly on analogy. Most stone circles and their contemporaries, long barrows, can be ascribed to the Aeneolithic period. We may here suggest a Bronze Age date. As regards the primary structure and the earthwork, the flints found in the ditch are no criterion, because they are implements roughly fashioned for rough work. The two pieces of pottery, however, found in the first silting of the ditch are almost certainly of the type called neolithic, and since the silting in the ditch must have been rapid we can speculate on a Stonehenge of the late Neolithic period superseded by an improved Stonehenge in the early Bronze Age.

STONE MONUMENTS, PRIMITIVE. The term primitive stone monument implies an ancient or rudimentary memorial or mark. Some represent men or things. Others are tabernacles, provided, either with pious or magical intent, that a power or a soul may be induced to dwell therein.

At first, they were memorial—to keep in memory the site of a certain event, or definite spot—perhaps to mark a route, perhaps to delimit the bourn of forbidden ground. They would be signposts, of a welcoming, funereal or warning character. Natural existing marks were doubtless first used; later, wooden posts where trees were plentiful. Stone heaps or boulders where available, would replace wood as less subject to decay and more difficult to remove treacherously. Such marks become sacred by natural evolution, so that men fear to remove them. This process varies according to the people's standard of magic or religion. Retribution is to be feared should a memorial be defaced or a boundary stone moved. During Woolley's excavation at Ur in 1924 there was found, in what appeared to be a museum or records department attached to a convent of the Kassite period (*c.* 1600 B.C.), such a bourn (now in the Baghdad Museum), photographs of which were exhibited in 1925 in the basement of the Assyrian Department at the British Museum. On this stone were graven the boundaries of the property it had presumably once marked, the names of the owner and of the witnesses to the "deed," and a short imprecation threatening the curses of the gods *whose emblems were carved upon the stone* should this testimony be destroyed. The stage from the bourn to the idea of

a witness-stone is almost imperceptible The stone becomes something on which solemn oaths can be sworn, as is exemplified by pillar-stones and their folk-lore, especially such as have a hole through which may be passed the clasped hands of two persons making a contract The *Lia Fail* at Tara and other stones on which Irish kings and chiefs took their oaths at their inauguration, and the *Bocca della Verita* in Rome, display the persistence of such an idea into historic times. Similar traditions have clung for longer periods to witness-stones or *pierres de justice* among the primitive stone monuments of Brittany, Cornwall, Wales, Scotland and Ireland.

Once a memorial pillar or a witness-stone became invested with such a sacral character it would easily itself become the object of propitiatory rites, especially if marked with sacred emblems. Thus the drivers travelling the lonely desert routes uniting India, China, Tibet, Russia and Persia pour libations of wheel oil on the anthropomorphic stone wayside cairns and sacred wooden pillars set up at certain stages of their road (*See* also *Genesis* xxviii, 16–22)

As to the representation of the human form or of its life-giving organs, the more primitive idea is not the symbology associated with fertility cults, but the intention to represent a particular man or a supernatural being in the likeness of man however crude This is demonstrable, because although standing-stones or menhirs rudely hewn into effigies, recognizably female by their indications of femininity (and almost certainly intended to represent or symbolize a Mother Goddess), are compatible with a very primitive knowledge of physiology, and call for no esoteric or philosophical explanation, the case with phallic (*see* PHALLICISM) representations is rather different. A religion calling for the recognition of that symbol as representative of fertility (as distinct from fecundity) presupposes a society cognizant of the respective parts played by the male and female functions in nature in the production of offspring, and long familiar with husbandry and cattle-raising, whereas in very primitive societies the physical association of the sexes, though regulated by custom, is often unrelated to paternity. The child is known to be physiologically produced by its mother. Socially it may belong to its maternal uncle (*see* AVUNCULATE), uterine relationship between brothers and sisters being easily demonstrable Even when the observed association of maternal fecundity with post-initiate sexual connection brings about recognition of cause and effect in specific cases, there is still some way to go intellectually before the symbol of male fertility can take the natural place in the ideology of magic or religion that is taken by the crude representation of a human form with female breasts The stone pillar that is recognizably a phallus is not on the same primitive plane with the menhir having indications of eyes, nose, mouth and breasts, but rather with the esoteric symbology of the holed stone.

Mystery dramas, in which the initiate actually passes through the circular gate of exit from "his mother's womb" to that new life, and domestic altars on which phallus and holed stone are not the accessories of indecent rites but the emblems of an exalted interpretation of the twin principles of life, must have been sufficiently common to perpetuate, as appears to have been the case, the esoteric significance of these symbols through long ages. We see the origin of the doubly solemn nature of an asseveration or contract made by passing the hand through a holed stone, and of the idea of passing sick children bodily through such stones. The cult of the *lingam* stone in India to-day illustrates this point.

Thus, no doubt, many of the rude stone monuments characteristic of Brittany, Cornwall, Wales, Scotland, Ireland, etc., came to have their connection in folk-lore and folk memory with fertility cults, the furtive practice of whose associated rites might well be condemned by the unthinking as fundamentally indecent, and by the early Christian Church as subversively pagan. Such monuments, therefore, are not so much primitive in themselves as relics of a highly elaborate order of ideas.

The ideas connected with pillar and holed-stone cults probably go back to 4000 or 5000 B.C., although not introduced into Western Europe till somewhere about 2500 to 2000 B.C. Long before that, however, men probably put up small rude bourns and memory stones (where stone was available) as more permanent than marked trees or wooden posts or cairns of loose stones. It is difficult to disentangle, from among a welter of stone monuments (such, *e g*, as those at Carnac which range from small unhewn pillars 2 feet high to elaborately chambered barrows), primitive commemorative menhirs that may have survived from an earlier day. The more primitive-seeming stone monuments—menhirs in isolation—are almost invariably found in districts where the elaborate chambered barrow, the cromlech and the stone avenue are equally characteristic. In the Naga Hills, lying between Assam and Burma, we can observe a rather primitive society erecting just such menhirs as we see in the megalithic districts of Western Europe, to mark social occasions and events of their lives Such primitive monuments as standing-stones are erected by men according to a prescribed etiquette to commemorate contemporary events of their own lives and need not necessarily be either funereal or in the nature of witness-stones or boundary-marks It is arguable that the stone-raising Nagas, like the peasants of Ireland or Brittany with their cults of the stones, are merely keeping alive customs which originated in a more complex society, and certain other Naga customs connected with the use of stone and the symbolism of horns bear this out

When, therefore, we come to deal with such stone monuments as are really rude human effigies, we are far away from the symbolical ideas already discussed. Primitive folk to-day provide the disembodied spirit with an effigy, preferably near his grave, thus preventing him from taking up his abode in an already occupied body.

Other rough stone monuments as avenues, cromlechs and quadrilateral enclosures, or dolmens—those remains of what have once been stone chambers or artificial grottoes covered over by mounds of earth or stones—are not strictly primitive, as has been demonstrated by the excavations at Carnac, in Brittany (*see* CARNAC, *Megalithic Monuments*).

STONE MOUNTAIN MEMORIAL. Stone mountain, situated about 15 m. north of Atlanta, Ga., is a solid grey granite monadnock, shaped like a half parabola, 867 ft high, nearly a mile long, and without a tree, shrub, or patch of earth to disguise the stone. In 1916 the sculptor, Gutzon Borglum (*q v*), conceived the plan of carving upon this mountain side a gigantic memorial to the valour and loyalty of the South to the lost Confederate cause. The design, 200 ft. high and 1,300 ft. long, was to represent the army of the Confederacy with Robert E. Lee and other southern leaders at its head. Work was begun by Borglum in 1917, interrupted by the World War, and continued in 1923–25 when a dispute with the Stone Mountain Monumental Association, which raised the funds, resulted in his dismissal In 1926 Augustus Lukeman was employed as Borglum's successor. Borglum's head of Lee was unveiled in 1924 and a section of Lukeman's work was unveiled in 1928, but the total then accomplished represented but a corner of one section of the complete design Funds may ultimately be raised to complete the monument.

STONE RIVER, BATTLE OF, a battle of the American Civil War, called the battle of Murfreesboro by the Confederates, fought on Dec. 31, 1862, and Jan. 2, 1863. After his appointment in October to command the Army of the Cumberland, Gen. W. S. Rosecrans, with Chattanooga as his objective, moved from Nashville upon Gen. Braxton Bragg, who left the winter quarters he had established at Murfreesboro and met the Union army on Stone river immediately north of Murfreesboro, on the last day of December. The plan of attack on each side was to crush the enemy's right. Bragg's left, commanded by Lieut.-gen. W. J.

Hardee, overlapped and bore back the Union right under Maj.-gen. A. McD. McCook, and Maj.-gen. T. L. Crittenden, commanding the Union left, was hurriedly called back from his attack on the Confederate right to support McCook. The Union right was crumpled up on the centre, where Maj.-gen. G. H. Thomas's corps checked the Confederate attack. There was practically no fighting on Jan. 1, but on the 2nd the Confederates renewed the attack, Maj.-gen. J. C. Breckinridge with Bragg's right attempting in vain to displace one of Crittenden's divisions which had established itself during the 1st on high ground across the river. On the night of the 3rd Bragg withdrew and the Union army occupied Murfreesboro. Tactically a drawn battle, Stone River was strategically a Union victory. The losses on both sides were heavy: of 37,712 Confederates present for duty, 1,294 were killed, 7,945 were wounded, and about 2,500 were missing; and of 44,800 Union soldiers present for duty, 1,677 were killed, 7,543 were wounded, and 3,686 were missing.

See A. F. Stevenson, *The Battle of Stone's River* (Boston, 1884); and W. J. Vance, *Stone's River, the Turning-Point of the Civil War* (1914).

STONEWORT, the common name for Algae (*q.v.*) of the division Charales, so called from the deposit of lime in their superficial membranes. They grow in fresh and brackish water.

STONINGTON, a borough of Connecticut, U.S.A. Pop. (1920), 2,100. There is a good harbour. In the 18th and 19th centuries whaling and sealing were important industries. Nathaniel B. Palmer, who discovered Palmer Land in the Antarctic early in the 19th century, was a whaling captain of Stonington. The village was a military depot during the Revolution, and in Aug. 1775, was bombarded by a British frigate. In 1801 it was incorporated as a borough, the first in the State. An attack by a British squadron in Aug. 1814, was repulsed.

STONY POINT, a township in Rockland county, N.Y., U.S.A. Pop. (1925) 3,511. Area, about 30 sq. miles. It was named from a rocky promontory which juts into the Hudson. During the Revolutionary War it was of considerable strategic importance. The Americans occupied it in Nov. 1776, and about two years later erected a blockhouse upon it. The garrison, however, was very small, and on May 31, 1779, it was taken by the British, who immediately erected much stronger fortifications. On the night of July 15–16, it was recovered by Gen. Anthony Wayne, in command of about 1,350 picked American troops, the garrison (under Lieut.-Col. Henry Johnson) losing 63 in killed, 70 in wounded and 543 taken prisoner. The American loss was only 15 killed and 83 wounded. The Americans, however, had no thought from the first of holding the place and evacuated it on July 18; whereupon it was reoccupied by the British, but late in October they, too, abandoned it. In the "old Treason house" in the township Gen. Benedict Arnold and Major John André met before daylight on Sept. 22, 1780, to settle upon plans for the surrender of West Point by Arnold to the British.

See H. P. Johnston, *The Storming of Stony Point* (1900); E. H. Hall and F. W. Halsey, *Stony Point Battle-Field* (1902); and D. Cole and E. Gay, *History of Rockland County* (1884).

STOOLBALL. Of the ancient game of stoolball very little indeed is known, and it has nothing whatever in common with the modern game which, since 1916, has made astonishing progress. During the war a simple but not strenuous outdoor game was very badly needed for wounded officers, soldiers and sailors; and the idea occurred to Maj. W. W. Grantham, who was stationed at Brighton, that the old game of stoolball adapted to modern requirements, would be suitable for the purpose. The game was soon played in scores of hospitals and convalescent homes, in England and France. He made a few simple rules adapted from cricket, and the first public match took place on the County cricket ground of Hove in 1917.

In 1924 a Stoolball Association was formed at Lord's, and by the end of 1927 it was estimated that nearly 3,000 clubs had become members. In Sussex alone the game is played in hundreds of villages, and by large numbers of schools of all kinds, women's institutions and girl guides associations. It has been introduced into Iceland, Japan, Siberia, Switzerland and Finland.

The materials required for the game are very few and very simple; and although with the exception of the ball they can be easily and quickly made by any carpenter they may now be obtained from most of the outfitters. Two bats, a ball, and two wickets comprise the materials. The bats are wooden, made like a racket, the diameter of the round part being not more than 7½in., and, including the handle, the bat must be not more than 18in. in length. The ball is usually known as "best tennis No. 3," but a hard lawn tennis ball will serve the purpose. Each of the two wickets consists of a board 1ft. square fastened to a stout post which must be firmly fixed in the ground in such a way that the top of the board is 4ft. 8in. above the ground; a tripod is often substituted for the post.

The wickets must be fixed at a distance of 16yds. from each other, and a bowling crease not more than 1yd. in length must be marked at a spot 10yds. from each wicket, for this is where the bowler stands. The bowling is underhand, and the number of balls to an over, originally ten, has been reduced to eight. A batsman may be bowled, caught, or run out (the ball hitting the face of the board), or may be given out "body before"; runs are made just as in cricket. In order that the batsman shall be out, "bowled," the ball must hit the face or edge of the wicket (but not the stump), without having previously touched the ground—in other words the ball must be a full pitch. On all points for which there are no special rules, the laws of cricket, as far as possible, hold good for stoolball. The game can be played on any piece of ground which is fairly level and not so rough as to be dangerous; the minimum space required would be about half the size of an ordinary cricket ground.

The ancient form of the game was once very popular in England, and was commonly considered to be the ancestor of cricket. Writing in 1801, Joseph Strutt gives a description of it.

See W. W. Grantham, *Stoolball Illustrated and How to Play it.*

(W. A. Be.)

STORACE, STEPHEN (1763–1796), English composer, was born in London but studied (under his father, Stefano Storace, an Italian contrabassist) at the Conservatorio di Sant' Onofrio, at Naples. His first opera, *Gli Sposi malcontenti*, was produced at Vienna, in 1785. Here he made the acquaintance of Mozart, in whose *Nozze di Figaro* his sister, Anna Selina Storace, first sang the part of Susanna. Here also he produced a second opera, *Gli Equivoci,* founded on Shakespeare's *Comedy of Errors*, and a Singspiel entitled *Der Doctor und der Apotheker*. In England, after creating a favourable impression by bringing out his Singspiel at Drury Lane, under the title of *The Doctor and the Apothecary,* Storace attained his first great success in 1789, in *The Haunted Tower*, an opera which ran for fifty nights in succession. The music of *The Pirates* (1792) affords one of the earliest instances of the introduction of a grand *finale* into an English opera. Storace's music is pre-eminently English. He doubtless learnt something from his sister Anna (1766–1817), a brilliant singer who died leaving £50,000. Storace himself died on March 19, 1796.

STORK (*Ciconia alba*), a well-known bird, which is a summer visitor to most parts of the European continent, breeding from southern Sweden to Spain and Greece. It reappears again in Asia Minor, the Caucasus, Persia, and Turkestan, but farther east it is replaced by *C. boyciana,* which reaches Japan. Though occasionally using trees for the purpose, the stork generally places its nest on buildings, and is everywhere a cherished guest, popular belief ascribing good luck to the house to which it attaches itself. To consult its convenience a stage of some kind, often a cartwheel, is in many places set up. Its food, consisting mainly of frogs and insects, is gathered in marshes and pastures, across which it may be seen stalking with an air of quiet dignity; but in the pairing season it indulges in grotesque gestures—leaping from the ground with extended wings in a kind of dance, and, though voiceless, clattering its mandibles. Apart from its size—a stork stands more than 3ft. in height—its contrasted plumage of white

and black, with its bright red bill and legs, makes it a conspicuous and beautiful object. In winter the storks of Europe retire to Africa—some of them reaching Cape Colony—while those of Asia visit India. A second species, with much the same range, is the black stork, *C. nigra,* of which the upper parts are black, brilliantly glossed with purple, copper and green, while it is white beneath, the bill, legs, and the bare skin round the eyes being red. The bird breeds in lofty trees. Two other dark-coloured species are the African *C. abdimii* and *C. episcopus,* which is found in Africa, India, Java, and Sumatra. The New World has only one true stork, *Dissura maguari,* which inhabits South America and resembles *C. boyciana,* differing therefrom in its greenish-white bill and black tail. Both these species are very like *C. alba,* but are larger and have a bare patch of red skin round the eyes.

The storks form the family *Ciconiidae,* and, together with the ibises (*q v.*), are ranked as a sub-order of Ciconiiform birds (*see* ORNITHOLOGY). In all the storks the eggs are white, and pitted with granular depressions

STORM, THEODOR WOLDSEN (1817–1888), German poet and novelist, was born at Husum, Schleswig, on Sept. 14, 1817, studying jurisprudence at Kiel and Berlin, where he formed a close friendship with the brothers Theodor and Tycho Mommsen Storm is hardly less remarkable as a lyric poet than as a novelist. As the former, he made his début, with the two Mommsens, with *Liederbuch dreier Freunde* (1843); but his *Gedichte* (1852; 12th edition, 1900) first obtained for him general recognition As a novelist he gained his first great success with *Immensee* (1852; 51st edition, 1901); and this was followed by numerous other short stories He is at his best when dealing retrospectively with episodes and incidents from his own earlier life. Later he passed to psychological problems with *Aquis submersus* (1877) and *Zur Chronik von Grieshuus* (1884), and made a deep impression with his fantastic *Schimmelreiter* (1888).

Storm's *Gesammelte Schriften* appeared in 19 vols. between 1868 and 1889; new edition in 8 vols. (1898); *Samtliche Werke* (A. Köster, 1919). His correspondence with E Morike was published in 1891, with G Keller in 1904 and with Paul Heyse (1917) *See* E Schmidt, *Charakteristiken,* i. (1886); also P Schutze, *Theodor Storm, sein Leben und seine Dichtung* (1887); F Wehl, *Theodor Storm, ein Bild seines Lebens und Schaffens* (1888), A Biese, *Th Storm und der moderne Realismus* (1888), and P. Remer, *Theodor Storm als norddeutscher Dichter* (1897); C J A Biese, *Theodor Storms Leben und Werke* (Leipzig, 1917); R. Pitnou, *La vie et l'oeuvre de Th Storm, 1817–1888* (1920).

STORM. A gale is classed as a storm when the wind reaches force 10 on the Beaufort Scale (*q v*) (For magnetic storms *see* TERRESTRIAL MAGNETISM.)

STORMBERG, ACTION OF (Dec 10, 1899): *see* SOUTH AFRICAN WAR

STORNOWAY (Norse, *Stjarna vagr,* "Stjarna's Bay"), the principal town of the county of Ross and Cromarty Pop (1921), 4,079 It is situated on the east coast of Lewis, at the head of a harbour accessible for steamers of 3,000 tons Stornoway, which was made a burgh of barony by James VI, is the centre of the Outer Hebrides fishery district and during the herring season the population is very largely increased Steamers run daily in summer to Hallaig and weekly to Glasgow, Belfast, Keith and Verpool.

STORY, JOHN (*c* 1510–1571), English martyr, was educated at Oxford, where he became lecturer on civil law in 1535, being made later principal of Broadgates Hall, afterwards Pembroke college. He appears to have disavowed his Roman Catholic opinions just after the accession of Edward VI, but having been chosen a member of parliament in 1547 he gained notoriety by his opposition to the act of uniformity in 1548. For crying out "Woe unto thee, O land, when thy king is a child," he was imprisoned by the House of Commons, but he was soon released and went into exile Returning to England in 1553, he resigned his position at Oxford, which was now that of regius professor of civil law, and was made chancellor of the dioceses of London and of Oxford and dean of arches Story was one of Queen Mary's most active agents in prosecuting heretics, and was one of her proctors at the trial of Cranmer at Oxford in 1555. Under Elizabeth he was again returned to parliament, but in 1560 he underwent a short imprisonment for boasting about his work in the former reign. In 1563 he was again arrested, but managed to escape to Flanders, where he became a pensioner of Philip II. of Spain. The duke of Alva authorized him to exclude certain classes of books from the Netherlands and, in 1570, while engaged in this work, he was decoyed on to a ship at Antwerp and conveyed to Yarmouth. In spite of his claim that he was a Spanish subject, he was tried for high treason, and executed at Tyburn on June 1, 1571. In 1886 Story was beatified by papal decree.

STORY, JOSEPH (1779–1845), American jurist, was born at Marblehead (Mass.), on Sept. 18, 1779 He graduated from Harvard in 1798, and was admitted to the bar at Salem (Mass.), in 1801, a Democrat. In Nov. 1811, at the age of 32, he became, by President Madison's appointment, an associate justice of the U S. Supreme Court. This position he retained until his death Soon after Story's appointment, the Supreme Court began to bring out into plain view the powers which the Constitution had given it over State courts and State legislation.

The leading place in this work belongs to Chief Justice John Marshall, but Story has a very large share in that remarkable series of decisions and opinions, from 1812 until 1832, by which the work was accomplished. In addition to this he built up the department of admiralty law in the U S. courts; he devoted much attention to equity jurisprudence, and rendered invaluable services to the department of patent law. In 1819 he attracted much attention by his vigorous charges to grand juries, denouncing the slave trade, and in 1820 he was a prominent member of the Massachusetts Convention called to revise the State Constitution. In 1829 he became the first Dane professor of law at Harvard university, and continued until his death to hold this position. He died at Cambridge (Mass), on Sept. 10, 1845

Among his publications are. *Commentaries on the Law of Bailments* (1832); *Commentaries on the Constitution of the United States* (1833), a work of profound learning which is still the standard treatise on the subject; *Commentaries on the Conflict of Laws* (1834), by many regarded as his ablest work; *Commentaries on Equity Jurisprudence* (1835–36); *Equity Pleadings* (1838); *Law of Agency* (1839); *Law of Partnership* (1841); *Law of Bills of Exchange* (1843), and *Law of Promissory Notes* (1845)

See *The Life and Letters of Joseph Story* (Boston and London, 1851), by his son, W W Story.

STORY, WILLIAM WETMORE (1819–1895), American sculptor and poet, was born at Salem (Mass), Feb 12, 1819 A graduate of Harvard college (1838), he studied law under his father, Justice Joseph Story and for six years he only wrote poetry and criticism, modelled and painted to amuse himself. A request that he make the public monument to his father resulted in a journey abroad, which caused him to find that his "heart had gone over from the Law to Art" Thereafter he spent his life in Italy, where he died, Oct. 7, 1895. What Hawthorne called "his perplexing variety of talents and accomplishments" prevented his high contemporary reputation from becoming permanent. His statue of Cleopatra is most famous because of the enthusiastic description in Hawthorne's *Marble Faun;* typical of the majority of his sombre feminine figures are *Semiramis* and *Medea* in the Metropolitan Museum. His *Poems* (1885), *He and She; or, A Poet's Portfolio* (1884) and *A Poet's Portfolio: Later Readings* (1894) show his love of beauty, but, like his statues, they lack vitality, as do his other books

See Mary E. Phillips, *Reminiscences of William Wetmore Story* (1897); Henry James, *William Wetmore Story and His Friends* (1903); and Lorado Taft, *History of American Sculpture* (1924).

STOSS, VEIT (1438 or 1440–1533), German sculptor and wood carver, was born in Nuremberg. In 1477 he went to Cracow, where he was actively engaged until 1499. It was here that he carved the high altar for the Marienkirche, between 1477 and 1484. On the death of King Casimir IV. in 1492 Stoss carved his tomb in red marble for the cathedral in Cracow. He also executed the marble tombstone of the archbishop Zbigniew Ollsnicki in the cathedral at Gnesen and the Stanislaus altar for the Marienkirche at Cracow. In 1496 he returned to Nuremberg, where he did a great deal of work in completing altars. His main works are: a relief with the Coronation of the Blessed Virgin in the Germanic museum at Nuremberg, a statue of the Blessed Virgin in the

Frauenkirche, the Annunciation in the Lorenzkirche, and the circular rosary in the Germanic museum.

STÖSSEL, ANATOLI MIKHAILOVICH (b. 1848), Russian general, born at St. Petersburg (Leningrad), on July 10, 1848, entered the Russian army in 1864. He served in the Russo-Turkish War of 1877–78 and in the Boxer campaign of 1900. At the outbreak of the Russo-Japanese War (1904) he was placed in command at Port Arthur. After a prolonged defence (*see* RUSSO-JAPANESE WAR) he surrendered the city to the Japanese (Jan. 2, 1905). He was tried by court-martial and imprisoned. Stössel was released in May 1909. The date of his death is uncertain.

STOTHARD, THOMAS (1755–1834), English subject painter, was born in London on Aug. 17, 1755, the son of a well-to-do innkeeper in Long Acre. After a delicate childhood, he was apprenticed in Spitalfields to a draughtsman of patterns for brocaded silks. In 1778 he became a student of the Royal Academy, of which he was elected associate in 1792 and full academician in 1794. In 1812 he was appointed librarian. He died in London on April 27, 1834.

Among his earliest book illustrations are plates engraved for *Ossian* and for *Bell's Poets;* and in 1780 he became a regular contributor to the *Novelist's Magazine,* for which he executed 148 designs, including his 11 admirable illustrations to *Peregrine Pickle* and his graceful subjects from *Clarissa* and *Sir Charles Grandison.* He contentedly designed plates for pocket-books, tickets for concerts, illustrations to almanacs, portraits of popular players—and into even the slightest and most trivial sketches he infused a grace and distinction which render them of value to the collectors of the present time. He is at his best in domestic or ideal subjects; the heroic and the tragic were beyond his powers.

His oil pictures are usually small in size, and rather sketchy in handling; but their colouring is often rich and glowing, Stothard having been a great admirer of Rubens. The "Vintage," perhaps his most important oil painting, is in the National Gallery. He was a contributor to Boydell's Shakespeare gallery, but his best-known painting is the "Procession of the Canterbury Pilgrims," also in the National Gallery, the engraving from which, begun by Luigi, continued by Niccolo Schiavonetti and finished by James Heath, attained an immense popularity. It was followed by a companion work, the "Flitch of Bacon," which was drawn in sepia for the engraver but was never carried out in colour.

Among his illustrations are the two sets to *Robinson Crusoe,* one for the *New Magazine* and one for Stockdale's edition, and the plates to *The Pilgrim's Progress* (1788), to Harding's edition of Goldsmith's *Vicar of Wakefield* (1792), to *The Rape of the Lock* (1798), to the works of Gessner (1802), to Cowper's *Poems* (1825), to *The Decameron,* the superb editions of Roger's *Italy* (1830) and *Poems* (1834).

Stothard also decorated the grand staircase of Burghley House, near Stamford (1799–1803); the mansion of Hafod, North Wales, (1810) and the cupola of the upper hall of the Advocates' Library, Edinburgh (now occupied by the Signet Library), with Apollo and the Muses, and figures of poets, orators, etc. (1822). His designs for a frieze and other decorations for Buckingham Palace were not executed, owing to the death of George IV. He also designed the magnificent shield presented to the duke of Wellington by the merchants of London, and executed with his own hand a series of eight etchings from the various subjects which adorned it. In the British Museum is a collection, in four volumes, of engravings of Stothard's works, made by Robert Balmanno.

An interesting but most indiscriminately eulogistic biography of Stothard, by his daughter-in-law, Mrs. Bray, was published in 1851. A. C. Coxhead's *Thomas Stothard, R. A., an Illustrated Monograph* (1906), contains a short biographical chapter, and an accurately dated summary of the various books and periodicals illustrated by Stothard; see also Austin Dobson, *Eighteenth Century Vignettes,* 1st series (1892).

STOUR, the name of several English rivers, an ancient word of doubtful etymology. (1) The East-Anglian Stour rises in south-east Cambridgeshire and flows 60 miles to the North Sea at Harwich. (2) The Kentish or Great Stour rises on the south of the North Downs, one branch, the East Stour, rising near Hyde but flowing away from the sea, while the western branch rises near Lenham and the two unite at Ashford. Passing Canterbury, the Stour again divides, one branch reaching the English Channel in Pegwell Bay, while the smaller enters the North Sea at Reculver. The Stour is navigable to Fordwich. Its length is about 40 m. Other rivers named Stour are (3) a tributary of the Hampshire Avon, (4) a left bank tributary of the Severn, which it joins at Stourport, and (5) a small tributary of the upper Avon, rising west of Banbury.

STOURBRIDGE, town in Worcestershire, England. Pop. (1921) 18,016. There is an endowed grammar school founded by Edward VI., and a bluecoat or hospital school. The principal manufactures are in iron, leather and skins; there are glue works and fire-brick works. Coal and fire-clay are mined. The manufacture of glass was established in 1556. Annual fairs are held. The town was originally called Bedcote, a name retained by the manor.

STOURPORT, market town, Worcester, England. Pop. (1921) 4,777. At Redstone is a hermitage excavated out of the red sandstone bank of the Severn.

STOUT, SIR ROBERT (1844–), New Zealand judge and statesman, was born on Sept. 28, 1844 at Lerwick, Shetland Isles, where he became a pupil teacher at the parish school. He went to New Zealand in 1863, was admitted (July 4, 1871) as barrister and solicitor of the supreme court of New Zealand, and from 1874–1876 was law lecturer there. In 1875 he was elected Liberal M.P. for Caversham, and in Feb. 1878 became attorney-general and minister of lands and minister of immigration in Sir George Grey's ministry. He resigned in 1879 but returned to public life in 1884 as member for Dunedin East. On the defeat of Sir Harry Atkinson's Government he joined Sir Jules Vogel in forming a ministry (Aug. 16–28, 1884), but after another Atkinson government had held office for a few days (Aug. 28–Sept. 3) a second Stout-Vogel government was formed which lasted three years. In both the Stout-Vogel governments Sir Robert Stout was prémier and attorney-general. At the general election in 1887 he lost his seat. In 1893 he was elected as an independent Liberal for Inangahua, at a by-election, and at the general elections of 1893 and 1896 he was elected for Wellington city, to which he transferred his legal practice. In 1898 he resigned his seat, and from 1899 to 1926 was Chief Justice.

Sir Robert Stout's principal measures were the Land Act of 1877, the first Land Tax Act (drafted in co-operation with Ballance and which became law in 1878), and the Civil Service Reform Act of 1886 when he was made K.C.M.G. As a member of a royal commission appointed in 1881 he helped Allen Holmes to form the code of civil procedure, which was enacted in 1882 and made the supreme court procedure of New Zealand one of the simplest in the world. He was also interested in educational and temperance reform. He became member of the New Zealand university senate in 1884 and of the Victoria University college council, Wellington, and from 1903 to 1923 was chancellor of the university. He was elected a member of the Legislative Council of New Zealand in 1926.

STOUT: *see* BEER; BREWING.

STOVES: *see* HOUSEHOLD APPLIANCES; GAS STOVES; FURNACES; HEATING AND VENTILATION.

STOW, JOHN (*c.* 1525–1605), English historian and antiquary, was the son of Thomas Stow, a tailor, and was born about 1525 in London, in the parish of St. Michael, Cornhill. He learned the trade of his father, but possibly did not practise it much after he grew up. In 1549 he "kept house" near the well within Aldgate, but afterwards he removed to Lime Street ward, where he resided till his death. About 1560 he made the acquaintance of the leading antiquaries of his time, including William Camden, and in 1561 he published his first work, *The woorkes of Geffrey Chaucer, newly printed with divers addicions whiche were never in printe before.* This was followed in 1565 by his *Summarie of Englyshe Chronicles,* which was frequently reprinted, with slight variations, during his lifetime. In 1580 Stow published his *Annales, or a Generale Chronicle of England from Brute until the present yeare of Christ 1580.*

The work by which Stow is best known is his *Survey of London,* published in 1598, not only interesting from the quaint simplicity of its style and its amusing descriptions and anecdotes, but of unique value from its minute account of the buildings, social condition and customs of London in the time of Elizabeth.

Through the patronage of Archbishop Parker, Stow was enabled to print the *Flores historiarum* of Matthew of Westminster in 1567, the *Chronicle* of Matthew Paris in 1571, and the *Historia brevis* of Thomas Walsingham in 1574. At the request of Parker he had himself compiled a "farre larger volume," *An history of this island,* but the manuscript is lost. Stow remained poor all his life, and was authorized by James I. to appeal for alms in 1604. He died on April 6, 1605, and was buried in the church of St. Andrew Undershaft, where is his monument.

A number of Stow's manuscripts are in the Harleian collection in the British Museum Some are in the Lambeth library (No. 306); and from the volume which includes them were published by the Camden Society, edited by James Gairdner, *Three Fifteenth-Century Chronicles, with Historical Memoranda by John Stowe the Antiquary, and Contemporary Notes of Occurrences written by him* (1880)

Of the many editions of Stow's *Survey of London, see* that with notes by C. L. Kingsford (Oxford, 1908).

STOWE, HARRIET ELIZABETH (Beecher) (1811–1896), American writer and philanthropist, seventh child of Lyman and Roxana (Foote) Beecher, was born at Litchfield (Conn), June 14, 1811 Her parents were descended from founders of New Haven; and the community in which she spent her childhood was one of the most intellectual in New England At her mother's death, in 1815, she came most directly under the influence of her eldest sister, Catherine, a woman of keen intellect, who a few years later set up a school in Hartford, to which Harriet went, first as a pupil, afterwards as teacher. In 1832 her father, who had for six years been the pastor of a church in Boston, accepted the presidency of the newly-founded Lane Theological seminary at Cincinnati. Catherine Beecher, who was eager to establish what should be in effect a pioneer college for women, accompanied him; and with her went Harriet as an assistant, taking an active part in the literary and school life, contributing stories and sketches to local journals, and compiling a school geography She was married Jan 6, 1836, to one of the professors in the seminary, Calvin Ellis Stowe. In the midst of privation and anxiety, due largely to her husband's precarious health, she wrote continually, and in 1843 published *The Mayflower, or Sketches of Scenes and Characters among the Descendants of the Pilgrims* She lived 18 years in Cincinnati, separated only by the Ohio river from a slave-holding community, coming in contact with fugitive slaves, and learning from friends and her own visits the life of the South. When, therefore, in 1850, Mr Stowe was elected to a professorship in Bowdoin college, Brunswick (Me), and removed his family thither, Mrs. Stowe was prepared for the great work which came to her, bit by bit, as a religious message which she must deliver. There she wrote, for serial publication in the *National Era,* an anti-slavery paper of Washington (D.C.), the story of *Uncle Tom's Cabin; or, Life Among the Lowly.* The publication in book form (March 20, 1852) was a factor which must be reckoned in summing up the moving causes of the Civil War. The book sprang into unexampled popularity, and was translated into at least 23 languages. Mrs. Stowe reinforced her story with *A Key to Uncle Tom's Cabin,* in which she accumulated a large number of documents and testimonies against the great evil, and in 1853 she made a journey to Europe, devoting herself especially to creating an *entente cordiale* between English and American women on the question. In 1856 she published *Dred: a Tale of the Dismal Swamp,* in which she threw the weight of her argument on the deterioration of a society resting on a slave basis. The establishment of the *Atlantic Monthly,* in 1857, gave her a constant vehicle for her writings; also the *Independent* of New York, and later the *Christian Union,* of which papers successively her brother, Henry Ward Beecher, was one of the editors.

From this time she led the life of a woman of letters, writing novels, of which *The Minister's Wooing* (1859) is best known, and many studies of social life in the form both of fiction and essay. Her *Pearl of Orr's Island* (1862), Sarah Orne Jewett credited with having revealed to her the literary value of the country folk. Mrs Stowe published also a small volume of religious poems, and towards the end of her career gave some public readings from her writings. In 1852 Prof. Stowe accepted a professorship in the Theological seminary at Andover (Mass.), and the family made its home there till 1863, when he retired wholly from professional life and removed to Hartford. After the close of the war for the Union, Mrs. Stowe bought an estate in Florida, chiefly in hope of restoring the health of her son, Capt. Frederick Beecher Stowe, who had been wounded in the war, and there she spent many winters. After the death of her husband in 1886, she lived in the seclusion of her Hartford home, where she died on July 1, 1896 She is buried by the side of her husband at Andover.

See the *Life and Letters of Harriet Beecher Stowe* (1897) which were edited by Annie Fields. Recent lives are C. E and L B Stowe, *Harriet Beecher Stowe: the Story of Her Life* (1911), and a biography for girls (1913) by Martha F Crow *See* also "Harriet Beecher Stowe" in John Erskine's *Leading American Novelists* (1910). The Riverside edition of Mrs. Stowe's works was published in 1899 and 1906 in 16 volumes (with an additional volume of biography). (H. E. S.)

STOWELL, WILLIAM SCOTT, Baron (1745–1836), English judge and jurist, was born at Heworth, near Newcastle, on Oct 17, 1745, the son of a "coalfitter" (or tradesman engaged in the transport of coal). His younger brother John became the famous Lord Chancellor Eldon. Scott was educated at the Newcastle grammar school and Corpus Christi College, Oxford. In 1774 he was Camden reader of ancient history, and in 1779 he graduated as doctor of civil law and, after the customary "year of silence," commenced practice in the ecclesiastical courts. His professional success was rapid. In 1783 he became registrar of the court of faculties; in 1788 judge of the consistory court and advocate-general; and in 1798 he was made judge of the high court of admiralty Sir William Scott twice contested Oxford University—in 1780 without success, but successfully in 1801 He also sat for Downton in 1790. Upon the coronation of George IV (1821) he was raised to the peerage as Baron Stowell. Lord Stowell retired from the bench—from the consistory court in August 1821, and from the high court of admiralty in December 1827. He died on Jan 28, 1836. Lord Stowell was twice married —in 1781 to Anna Maria, eldest daughter of John Bagnall of Early Court, Berks, and in 1813 to the dowager marchioness of Sligo. The doctrines of international law with the assertion and illustration of which the name of Lord Stowell is identified are these: the perfect equality and entire independence of all states (*"Le Louis,"* 2 Dod 243)—a logical deduction from the Austinian philosophy and still one of the fundamental principles of English jurisprudence; that the elementary rules of international law bind even semi-barbarous states (the *"Hurtige Hane,"* 2 Rob 325); that blockade to be binding must be effectual (the *"Betsey,"* 1 Rob 93); and that contraband of war is to be determined by "probable destination" (the *"Jonge Margaretha,"* 1 Rob 189) In the famous Swedish convoy case (the *"Maria,"* 1 Rob. 350; *see,* too, the *"Recovery,"* 6 C. Rob. 348–9) Lord Stowell asserted that "a prize court is a court not merely of the country in which it sits but of the law of nations" "The seat of judicial authority," he added, in words which have become classic, "is indeed locally here, in the belligerent country, but the law itself has no locality" His dictum concerning the right of a belligerent to sink a neutral ship, when unable to take her before a prize court, was much quoted in 1904 in reference to the sinking of the "Knight Commander" by the Russians in the Far East

The judgments of Lord Stowell were, almost without exception, confirmed on appeal, and they are to this day the international law of England, and have become presumptive though not conclusive evidence of the international law of America. "I have taken care," wrote Justice Story, "that they shall form the basis of the maritime law of the United States, and I have no hesitation in saying that they ought to do so in that of every civilized country in the world"

See W. C. Townsend, *Lives of Twelve Eminent Judges,* vol. ii. (2 vols., 1846); W E. Surtees, *Sketch of the Lives of Lords Stowell and Eldon* (1846); E. S. Creasy, *First Platform of International Law: Reports of Prize Cases from 1745 to 1859* (1876; new ed E. S. Roscoe, 2 vols., 1905), contains the most important of Stowell's judgments.

STOWMARKET, a town in Suffolk, England. Pop. 4,243. The church of St. Peter and St. Mary is Decorated and Early English, with a tower and wooden spire. The ancient vicarage has associations with Milton through his tutor, Dr. Young.

STRABANE, the principal town of Co. Tyrone, Ireland. Pop. (1921) 5,107. It stands at the junction of the rivers Mourne and Finn, which thenceforward form the Foyle. The trade in corn is considerable. Linen is the principal industry.

STRABO [STRABON] (born *c.* 63 B.C.), Greek geographer, was born at Amasia in Pontus, a city which had been much Hellenized. He studied at Nysa under the grammarian Aristodemus, under the grammarian Tyrannio at Rome, under the philosopher Xenarchus, and he studied Aristotle with Boethus. He also states that he saw P. Servilius Isauricus, who died at Rome in advanced years in 44 B.C., from which it has been inferred that he visited Rome early in life. He also tells us that he was at Gyaros (one of the Cyclades) when Augustus was at Corinth on his return to Rome from the East in 29 B.C., and that he accompanied the prefect of Egypt, Aelius Gallus, on his expedition to Upper Egypt, which seems to have taken place in 25–24 B.C. These are the only dates in his life which can be accurately fixed. The latest event mentioned in his work is the death of Juba, king of Mauretania, which took place in A.D. 21.

Although he had seen a comparatively small portion of the regions which he describes, he had travelled much. As he states himself: "Westward I have journeyed to the parts of Etruria opposite Sardinia; towards the south from the Euxine to the borders of Ethiopia." His *Geography* was finally revised between A.D. 17 and 23.

Works.—His earliest writing was an historical work now lost, which he himself describes as his *Historical Memoirs.* He tells us (xi. 9, 3) that the sixth book of the *Memoirs* was identical with the second of the *Continuation of Polybius;* probably, therefore, books i.–iv. formed an introduction to the main work. Plutarch, who calls him "the Philosopher," quotes Strabo's *Memoirs* (*Luc.* 28), and cites him as an historian (*Sulla,* 26). Josephus calls him "the Cappadocian," and often quotes from him.

The *Geography* is the most important work on that science which antiquity has left us. It follows Eratosthenes, who had first laid down a scientific basis for geography. The earlier book was too small to contain the description of separate countries which Strabo included. The historical notices are all his own. He regarded Homer as the source of all wisdom and knowledge—indeed, his description of Greece is largely drawn from Apollodorus's commentary on the Homeric "Catalogue of Ships"—and treated Herodotus with undeserved contempt, classing him with Ctesias and other "marvel-mongers."

Strabo chiefly employed Greek authorities (the Alexandrian geographers Polybius, Poseidonius and Theophanes of Mytilene, the companion of Pompey) and made comparatively little use of Roman authorities. He probably amassed his material in the library of Alexandria, so that Greek authorities would naturally furnish the great bulk of his collections, and then returned to Rome, where he perhaps used the chorography of Agrippa, a map of the Roman Empire set up in the Porticus Vipsaniae.

The *Geography* consists of seventeen books, of which the seventh is imperfect. The first two are introductory, the next eight deal with Europe, two being devoted to Spain and Gaul, two to Italy and Sicily, one to the north and east of Europe, and three to Greek lands. The eleventh book treats of the main divisions of Asia and the more easterly districts, the next three of Asia Minor. Book xv. deals with India and Persia, book xvi. with Assyria, Babylonia, Syria and Arabia, and the closing book with Egypt and Africa.

Editions.—The Aldine (Venice, 1516) was unfortunately based on a very corrupt ms. The first substantial improvements in the text were due to Casaubon (Geneva, 1587; Paris, 1620), whose text remained the basis of subsequent editions till that of Coraës (Paris, 1815–19), who removed many corruptions. The mss. were first scientifically collated by Kramer (Berlin, 1844–52), who demonstrated that Par. 1,397 was the best authority for the first nine books (it contains no more) and Vat. 1,329 for the remainder. Of later editions the most important are those of C. Müller (Paris, 1853) and Meineke (Leipzig, 1866–77). H. F. Tozer's volume of selections (Oxford, 1893) is useful. Napoleon I., an admirer of Strabo, caused a French translation of the *Geography* to be made by Coraës, Letronne and others (Paris, 1805–19); German translation by Grosskurd (Berlin, 1831–34); Eng. trans. by H. L. Jones, Loeb Classical Lib. (5 vols. 1922–28). For fragments of the *Historical Memoirs* see *Leipziger Studien XI.*, 1891. *See* also Müller's *Fragmenta historicorum graecorum*, iii. 490 *sqq.;* Bunbury's *History of Ancient Geography,* vol. ii. chs. 21, 22; and F. Dubois's *Examen de la géographie de Strabon* (Paris, 1891) should also be consulted.

STRACHAN, JOHN (1778–1867), first bishop of Toronto, was born at Aberdeen, Scotland, on April 12, 1778. After taking his degree at Aberdeen he emigrated in 1799 to Canada. There he was ordained (1803) and appointed to the parish of Cornwall, and in 1812 to York.

Strachan was appointed to the executive council of Upper Canada in 1815. He was soon the leading spirit in that dominant group known in Upper Canadian history as the Family Compact. In 1820 he was appointed by Sir Peregrine Maitland a member of the legislative council in order that the governor might have a confidential medium through whom to make communication to the council. At the instance of the lieutenant-governor he went to England in 1824, to discuss various colonial questions with the colonial secretary. He paid a second visit to England in 1826–27 to obtain a royal charter for King's College. In 1827 Strachan became archdeacon of York.

The break-up of the Liverpool ministry in 1827 interrupted Strachan's plans for placing the government endowments for religion and education under the Episcopal Church. Adverse criticism and a suggestion from the colonial office led to his resignation from the executive council, but he declined to resign from the legislative council.

On the death of Bishop Stewart of Quebec the Canadian see was divided, and Strachan was made bishop of Toronto in August 1839. He energetically opposed the act of 1840, which sought to settle the Clergy Reserves question by dividing the proceeds among the different religious denominations, the larger share still remaining with the Church of England.

The university of King's College was finally established, with certain modifications of its charter, in 1843, Bishop Strachan being the first president. The renewed agitation finally resulted in the elimination of all religious tests by the act of 1849, which also changed the name to that of the university of Toronto. Strachan at once took steps to found another university which should be completely under the control of the Episcopal Church, hence the establishment of Trinity University, which was opened in 1852. Bishop Strachan also raised once more the question of the disposal of the Clergy Reserves. The Reserves were completely secularized in 1854, provision being made for the life-interest of beneficiaries at the time. Bishop Strachan devoted the latter years of his long life entirely to his episcopal duties, and by introducing the diocesan synod he furnished the Episcopal Church in Canada with a more democratic organ of government. He died in November 1867.

STRACHEY, JOHN ST. LOE (1860–1927), British journalist, was born at Sutton Court, Somerset, on Feb. 9, 1860, the second son of Sir Edward Strachey, 3rd Bart., and Mary Isabella, daughter of John Addington Symonds. He studied at Balliol College, Oxford, and was called to the bar, but adopted journalism as his profession. After writing for some time for the *Saturday Review,* the *Economist,* and other papers, he became in 1886, with Mr. Charles Graves, editor of the *Liberal Unionist,* and in the same year assistant editor of the *Spectator.* After the death of R. H. Hutton and the retirement of Meredith Townsend (1897) he became proprietor of the *Spectator,* which, under his editorship not only maintained but increased its great influence upon English opinion. St. Loe Strachey also edited (1896–97) *The Cornhill Magazine.* He resigned from the editorship of the *Spectator* in 1925, but continued to contribute to its columns.

His publications include *The Manufacture of Paupers* (1907); *The Problems and Perils of Socialism* (1908); *The Practical Wisdom of the Bible* (1908); *A New Way of Life* (1909); *The Madonna of the Barricades* (a novel, 1925); *American Soundings* (1926).

STRACHEY, LYTTON (1880–), British writer, son of Sir Richard Strachey, the Indian administrator, was born on March 1, 1880, and educated at Trinity college, Cambridge. He was an occasional contributor to the monthly and quarterly

reviews, and published a short but illuminating book on *Landmarks in French Literature* (1912). He achieved wider renown by *Eminent Victorians* (1918), vivid, polished and unusually caustic portraits of Cardinal Manning, Florence Nightingale, Dr. Arnold and General Gordon. In *Queen Victoria* (1921) Strachey's biographical power and his ironic style showed themselves broadened and mellowed, the result being a most successful blend of sympathy and detachment in depicting the queen, her family and her epoch. The two books set up a fresh standard for modern English biography which a good many contemporary writers were quick to acknowledge. A collection of essays, *Books and Characters,* appeared in 1922, his "Leslie Stephen" lecture on Pope in 1925, and *Elizabeth and Essex* in 1928.

STRACHWITZ, MORITZ KARL WILHELM ANTON, GRAF VON (1822–1847), German poet, was born on March 13, 1822, at Peterwitz near Frankenstein in Silesia. After studying in Breslau and Berlin he settled on his estate in Moravia, where he devoted himself to literary pursuits. When travelling in Italy in 1847 he was taken ill at Venice, and died on Dec. 11 at Vienna in his 25th year. He had already revealed a lyric genius of remarkable force and originality. His first collection of poems, *Lieder eines Erwachenden,* appeared in 1842 and went through several editions. *Neue Gedichte* were published in 1848.

Strachwitz's collected *Gedichte* appeared first in 1850 (8th ed., 1891); a convenient reprint will be found in Reclam's *Universal-bibliothek. See* A. K. T. Tielo, *Die Dichtung des Grafen Moritz von Strachwitz* (1902).

STRADELLA, ALESSANDRO (?1645–1682), Italian composer, one of the most accomplished musicians of the 17th century, was probably born at Naples. The generally accepted story of his life was first circumstantially narrated in Bonnet-Bourdelot's *Histoire de la musique et de ses effets* (1715). According to this account, Stradella was engaged by a Venetian nobleman to instruct his mistress, Ortensia, in singing Stradella eloped with Ortensia to Rome, whither the outraged Venetian sent two paid *bravi* to put him to death. On their arrival in Rome the assassins learned that Stradella had just completed a new oratorio, over the performance of which he was to preside on the following day at S. Giovanni in Laterano. They determined to kill him as he left the church; but the beauty of the music conquered them, and they warned the composer of his danger. Thereupon Stradella fled with Ortensia to Turin, where, notwithstanding the favour shown to him by the regent of Savoy, he was attacked one night by another band of assassins, who, headed by Ortensia's father, left him on the ramparts for dead. Through the connivance of the French ambassador the ruffians escaped; and Stradella, recovering from his wounds, married Ortensia, by consent of the regent, and removed with her to Genoa. Here he believed himself safe; but a year later he and Ortensia were murdered in their house by a third party of assassins in the pay of the implacable Venetian. Research has, however, driven several holes in this picturesque story.

The first certain date in Stradella's life is 1672, in which year he composed a prologue for the performance of Cesti's opera *La Dori* at Rome; he probably spent a considerable time at Rome about this period, since his cantatas and other compositions contain frequent allusions to Rome and noble Roman families. There is, however, no proof that he ever performed the oratorio *S. Giovanni Battista* in the Lateran. Documents in the archives at Turin relate that in 1677 he arrived there with the mistress of Alvise Contarini, with whom he had eloped from Venice. We hear of Stradella last at Genoa. An opera by him, *La Forza dell' amor paterno,* was given there in 1678, and his last composition, *Il Barcheggio* (*i.e.,* a "Water-Music"), was performed on June 16, 1681 in honour of the marriage of Carlo Spinola and Paola Brignole. That he died at Genoa in Feb. 1682 is established by documents in the archives at Modena.

Stradella's best operas are *Il Floridoro,* also known as *Il Moro per amore,* and *Il Trespolo tutore,* a comic opera in three acts which worthily carried on the best traditions of Florentine and Roman comic opera in the 17th century. The oratorio *S. Giovanni Battista* displays the same skill in construction and orchestration (so far as the limited means at his disposal permitted) as the operas A serenata for voices and two orchestras, *Qual prodigo ch'io miri,* was used by Handel as the basis of several numbers in *Israel in Egypt,* and was printed by Chrysander (Leipzig 1888); the MS., however, formerly in the possession of Victor Schoelcher, from which Chrysander made his copy, has entirely disappeared. The well-known aria *Pietà, signore,* also sung to the words *Se i miei sospiri,* cannot possibly be a work of Stradella.

The finest collection of Stradella's works extant is that at the Biblioteca Estense at Modena, which contains 148 MSS., including four operas, six oratorios and several other compositions of a semi-dramatic character.

See Heinz Hess, *Die Opern Alessandro Stradellas* (Leipzig, 1905), which includes the most complete catalogue yet made of Stradella's extant works; Catelani, *Delle Opere di A Stradella instenti nell' archivio musicale della r. biblioteca palatina di Modena* (Modena, 1865); and Sedley Taylor, *The Indebtedness of Handel to other Composers* (Cambridge, 1906).

STRADIVARI, ANTONIO (1644–1737), Italian violin-maker, was associated throughout his life with Cremona, where he brought the craft of violin-making to its highest pitch of perfection. The obscure details of his life have been thoroughly worked out in the monograph on him by W H Hill, A. F. Hill and Alfred Hill (1902) He was still a pupil of Nicolas Amati in 1666, when he had begun to insert his own label on violins of his making, which at first follow the smaller Amati model, solidly constructed, with a thick yellow varnish. It was not till 1684, that he began to produce larger models, using a deeper coloured varnish, and beautifying them in various details, his "long" patterns (from 1690) representing a complete innovation in the proportions of the instrument; while from 1700, after for a few years returning to an earlier style, he again broadened and otherwise improved his model He also made some beautiful violoncellos and violas. The most famous instruments by him are:—*Violins:* the "Hellier" (1679), the "Sellière" (before 1680), the "Tuscan" (1690), the "Betts" (1704), the "Ernst" (1709), "La Pucelle" (1709), the "Viotti" (1709), the "Vieuxtemps" (1710), the "Parke" (1711), the "Boissier" (1713), the "Dolphin" (1714), the "Gillot" (1715), the "Alard," the finest of all (1715), the "Cessot" (1716), the "Messiah" (1716), the "Sasserno" (1717), the "Maurin" (1718), the "Lauterbach" (1719), the "Blunt" (1721), the "Sarasate" (1724), the "Rode" (1722), the "Deurbroucq" (1727), the "Kiesewetter" (1731), the "Habeneck" (1736), the "Muntz" (1736). *Violas:* the "Tuscan" (1690), two of 1696 formerly belonging to the king of Spain, the "Archinto" (1696), the "Macdonald" (1701), and the "Paganini" (1731). *Violoncellos:* the "Archinto" (1689), the "Tuscan" (1690), the "Aylesford" (1696), the "Cristiani" (1700), the "Servais" (1701), the "Gore-Booth" (1710), the "Duport" (1711), the "Adam" (1713), the "Batta" (1714), the "Piatti," the finest of all (1720), the "Bandiot" (1725), the "Gallay" (1725). Antonio Stradivari's sons Francesco (1671–1743) and Omobono (1679–1742) were also violin-makers, who assisted their father, together with Carlo Bergonzi, who appears to have succeeded to the possession of Antonio's stock-in-trade. The Stradivari method of violin-making created a standard for subsequent times; but the secret of his varnish, soft in texture, and shading from orange to red, though much debated, has never been discovered. (*See* also VIOLIN.)

STRAFFORD, THOMAS WENTWORTH, EARL OF (1593–1641), English statesman, son of Sir William Wentworth, of Wentworth Woodhouse, near Rotherham and of Anne Atkins, was born on April 13, 1593, in London. He was educated at St. John's College, Cambridge, was admitted a student of the Inner Temple in 1607. In 1614 he represented Yorkshire in the Addled Parliament, but, so far as is now known, it was not till the parliament of 1621, in which he sat for the same constituency, that he took part in the debates.

Wentworth was returned for Pontefract to the parliament of 1624, but appears to have taken no part in the proceedings. In the first parliament of Charles I., June 1625, he again represented Yorkshire, and opposed the demand made under the influence of Buckingham for subsidies for a war with Spain, and was consequently, after the dissolution in November, made sheriff of Yorkshire, in order to exclude him from the parliament which met

in 1626. Yet his position was very different from that of the regular opposition. He was anxious to serve the Crown, but he disapproved of the king's policy. After the dissolution of the parliament he was dismissed from the justiceship of the peace and the office of *custos rotulorum* of Yorkshire, to which he had been appointed in 1615. He refused in 1627 to contribute to the forced loan, and was imprisoned in consequence.

In the parliament of 1628 Wentworth joined the popular leaders in resistance to arbitrary taxation and imprisonment, but he was jealous for the prerogative of the Crown, to which he looked as a reserve force in times of crisis. A moderate bill supported by Wentworth for securing the liberties of the subject was wrecked between the uncompromising demands of the parliamentary party, who would give nothing to the prerogative, and Charles's refusal to make the necessary concessions, and the leadership was thus snatched from Wentworth's hands by Eliot and Coke. Later in the session he fell into conflict with Eliot, as he desired to modify the Petition of Right.

On July 22, 1628, Wentworth was created Baron Wentworth, and received a promise of the presidentship of the Council of the North at the next vacancy. He was now at variance with the parliamentary party both on the constitutional and on the religious question. In December he became Viscount Wentworth and president of the Council of the North. In the speech delivered at York on his taking office he said, almost in the words of Bacon: "Whoever," he said, "ravels forth into questions the right of a king and of a people shall never be able to wrap them up again into the comeliness and order he found them."

The session of 1629 ended in a breach between the king and the parliament which made the task of a moderator hopeless. He stood definitely for the maintenance of the king's prerogative.

The Policy of Thorough.—In January 1632 Wentworth was named lord-deputy of Ireland, and he arrived in Dublin in July 1633. He reformed the administration, getting rid summarily of the inefficient English officials. He obtained the necessary grants from parliament, and secured its co-operation in various useful legislative enactments. He set on foot a new victualling trade with Spain, established or promoted the linen manufacture, and encouraged the development of the resources of the country in many directions. The customs rose from a little over £25,000 in 1633–1634 to £57,000 in 1637–1638. He raised an army. He swept the pirates from the seas. He reformed and instilled life into the Church and rescued church property. His strong and even administration broke down the tyranny of the great men over the poor. Such was the government of "Thorough," as Strafford expresses it. Yet these good measures were carried out by arbitrary methods, and their aim was the benefit to the English exchequer; Strafford suppressed the trade in cloth "lest it should be a means to prejudice that staple commodity of England." Extraordinary acts of despotism took place, as in the case of Esmond, Lord Chancellor Loftus and Lord Mountnorris, the last of whom Strafford caused to be sentenced to death in order to obtain the resignation of his office, and then pardoned. Strafford broke Charles's promise that no colonists should be forced into Connaught, and, raking up an obsolete title—the grant in the 14th century of Connaught to Lionel, duke of Clarence, whose heir Charles was—he insisted upon the grand juries in all the counties finding verdicts for the king. High-handed as Wentworth was by nature, his rule in Ireland made him more high-handed than ever. As yet he had never been consulted on English affairs, and it was only in February 1637 that Charles asked his opinion on a proposed interference in the affairs of the Continent. In reply, he assured Charles that it would be unwise to undertake even naval operations till he had secured absolute power at home. He wished that Hampden and his followers "were well whipped into their right senses." When the Scottish Puritans rebelled he advocated the most decided measures of repression, in February 1639 sending the king £2,000 as his contribution to the expenses of the coming war, but he deprecated action before the English army was trained, and advised concessions in religion.

Wentworth arrived in England in September 1639, after Charles's failure in the first Bishops' War, and from that moment he became Charles's principal adviser. In January 1640 he was created earl of Strafford, and in March he went to Ireland to hold a parliament, where the Catholic vote secured a grant of subsidies to be used against the Presbyterian Scots. An Irish army was to be levied to assist in the coming war. When in April Strafford returned to England he found the Commons holding back from a grant of supply, and tried to enlist the peers on the side of the king. On the other hand he induced Charles to be content with a smaller grant than he had originally asked for. The Commons, however, insisted on peace with the Scots. Charles, on the advice of Vane, returned to his larger demand of twelve subsidies; and on May 9, at the privy council, Strafford, though reluctantly, voted for a dissolution. The same morning the Committee of Eight of the privy council met again. Vane and others were for a mere defence against invasion. Strafford's advice was for a vigorous prosecution of war.

Bill of Attainder.—The Long Parliament assembled on Nov. 3, 1640, and Charles immediately summoned Strafford to London. Under safe conduct from Charles, he arrived on the 9th and on the 10th proposed to the king to forestall his impeachment, now being prepared by the parliament, by accusing the leaders of the popular party of treasonable communications with the Scots. But Pym immediately took up the impeachment to the Lords on the 11th. Strafford came to the house to confront his accusers, but was ordered to withdraw and committed into custody. On Nov. 25, the preliminary charge was brought up, whereupon he was sent to the Tower, and, on Jan. 31, 1641, the accusations in detail were presented. These were, in sum, that Strafford had endeavoured to subvert the fundamental laws of the kingdom. Behind the legal aspect of the case lay the great constitutional question of the responsibility to the nation of the leader of its administration. The Commons, convinced that the destruction of Strafford was essential to the liberties of the kingdom, dropped the impeachment, and brought in and passed a bill of attainder, though, owing to the opposition of the Lords and Pym's own preference for the more judicial method, the procedure of an impeachment was practically adhered to. Strafford might still have been saved but for the king's ill-advised conduct. The revelation of the army plot on May 5, caused the Lords to pass the attainder. Nothing now remained but the king's signature. Charles yielded, giving his assent on May 10. Strafford met his fate on May 12, on Tower Hill, receiving Laud's blessing, who was then also imprisoned in the Tower, on his way to execution.

Thus passed into history "the great person," as Clarendon well calls him, without doubt one of the most striking figures in the annals of England. Strafford's patriotism and ideas were fully as noble as those of his antagonists. Like Pym, a student of Bacon's wisdom, he believed in the progress of England along the lines of natural development, but that development, in opposition to Pym, he was convinced could only proceed with the increase of the power of the executive, not of the parliament, with a government controlled by the king and not by the people.

Strafford was married three times: (1) in 1611 to Lady Margaret Clifford, daughter of Francis, 4th earl of Cumberland; (2) in 1625 to Lady Arabella Holles, daughter of John, 1st earl of Clare; (3) in 1632 to Elizabeth, daughter of Sir Godfrey Rhodes. He left three daughters and one son, William, 2nd earl of Strafford.

See the article on Strafford in the *Dict. Nat. Biog.* by S. R. Gardiner; Strafford's *Letters*, ed. by W. Knowler (1739); R. Browning's *Life of Strafford*, with introduction by C. H. Firth (1892); *Papers relating to Thos. Wentworth* ed. by C. H. Firth for the Camden Society (1890), Camden *Miscellany*, vol. ix.; *Private Letters from the Earl of Strafford to his third Wife* (Philobiblon Soc. Biog. & Hist. Misc. 1854, vol. i.); *Lives* by H. D. Traill (1889) in "English Men of Action Series," and by Elizabeth Cooper (1886); *Cat. of State Papers, Domestic and Irish, esp. 1633–1647 Introduction; Hist. MSS. Comm. MSS. of Earl Cowper;* Strafford's *Correspondence*, of which the volumes published by Knowler represent probably only a small selection, remains still in MS. in the collection of Earl Fitzwilliam at Wentworth Woodhouse; also H. O'Grady, *Strafford and Ireland* (Dublin, 2 vols., 1923).

STRAITS QUESTION, THE. The Straits Question is composed of diverse elements—political, economic, sentimental. In its simplest form it consisted in the desire of Russia to control

the straits of the Bosphorus and Dardanelles—the doors to the Black Sea—and to obtain the sacred city of her religious dreams —Constantinople. Although forming a part of the greater Eastern Question (*q.v.*), it was not co-extensive with that question; but throughout the 19th and early 20th centuries was solely concerned with the narrower issue of the disposal of Constantinople and the Straits in event of a break-up of the Ottoman power in Europe. Moreover, compared with other great political issues, the Straits Question is of very recent date

Peter the Great.—Although known to the Ancient World as an economic and strategic problem in a very rudimentary form, it only emerged as an actual political problem in the 18th century, and then thanks to the initiative and imperialistic ambitions of a Russian tsar—Peter the Great. By his establishment of arsenals in the Crimea, and on the shores of the Sea of Azov, and by his foundation of a Russian navy, Peter the Great initiated that southward expansion of Russia so energetically furthered by his successors.

If not the first to perceive that nature had placed a severe handicap upon Russia in her struggle with the other nations by virtually excluding her from access to an ice-free sea, Peter was undoubtedly the first Russian tsar to understand the full complications of that handicap. Unless Russia were to secure access to an ice-free sea, she would start on an unequal footing with other nations in the race for world-power. Ever since Peter the Great's death Russia has unswervingly pursued the aim of obtaining a free outlet from the Black Sea to the Mediterranean for her military and mercantile marine Since the attainment of that object presupposed the destruction of the Ottoman power in Europe, and the acquisition of Constantinople by Russia, the Mediterranean powers—France, England and Austria, as well as the Sultan, were concerned to frustrate the Russian design. Hence throughout the 19th century the Straits Question resolved itself into a contest between Russia and the Western Powers for the eventual possession of Constantinople and the Straits. Throughout the contest Turkey was little more than a tool in the hands of the rival protagonists, while Austria, whose interests were less directly threatened than those of France and England by a possible Russian acquisition of Constantinople, essayed intermittently to play the honest broker. Later, the emergence of a united Italy introduced a new factor

International Policy.—The diplomatic negotiations which centred from time to time round this problem were long and tortuous; but it is only possible to describe in brief outline the general trend of those negotiations, and of the policies pursued by the several powers After the Treaty of Adrianople (Sept. 14, 1829) Russia seemed to be on the point of realizing her ambition. Under the Treaty of Paris (1856) she was forced temporarily to relinquish her project and to suffer the annihilation of her naval power in the Black Sea

Russian Self-assertion.—The years (1856–70) that intervened between the conclusion of the Paris Treaty and the unilateral denunciation in 1870 of its Black Sea provisions by Russia, who seized the opportunity afforded by the Franco-Prussian war to free herself from the humiliating composition of 1856, were filled with protests from England against alleged infractions of the treaty by Russia In the negotiations that preceded the assembling of the Conference of London (1870–71), and at the conference itself, England took the lead in insisting upon a formal withdrawal by Russia of her unilateral denunciation as the price for the actual removal of the neutralization of the Black Sea. At this conference England stood almost alone in opposition to Russia. France was too weak to render effective support; Favre indeed hoped to purchase Russian mediation with Prussia by a sympathetic attitude towards her in the Straits Question, while Bismarck had almost certainly secured Russian neutrality in the war by promising Gortchakov his co-operation towards revising the Paris Treaty in the sense desired by Russia. Austria alone supported England. But Austria was too fearful of the new might of Prussia, and her Foreign Minister, Beust, was too much of an opportunist (in 1867 he had attempted to gain Russia's friendship by promising his assistance in obtaining a revision of the Paris Treaty) for her support to be of real value.

As the century advanced, various discussions were initiated (notably in 1885 and 1894) over a possible alteration in the existing regime of the Straits; but always without result. England held tenaciously to her traditional belief that the presence of a Russian fleet in the Mediterranean would be a menace to the Suez Canal. In 1894 Lord Rosebery, then Secretary of State for Foreign Affairs and about to succeed to the premiership, actually declared to the Austrian Ambassador, Count Deym, that any attempt by Russia to change the existing situation in regard to the Straits would be looked upon by the British Government as affording a *casus belli.* Nor was Sir Edward Grey (later Viscount Grey of Fallodon) more sympathetic towards Isvolsky's suggestion in 1908 that the time had perhaps come for a revision of the Convention of 1841 in a sense favourable to Russia. It was doubtless urgent necessity that forced Sir Edward Grey in 1915 to reverse England's traditional policy by assenting to the conclusion of the Straits Agreements, by which Russia was promised the fulfilment of her long-cherished ambitions at the conclusion of peace.

The Straits Convention of 1923.—At the end of the World War Russia was no longer in a position to enforce execution of the 1915 Agreement. The Straits Convention of July 24, 1923, however, actually imposed a settlement answering to Russia's traditional ambition. Ironically enough, at the Lausanne Conference at which the convention was drawn up, Russia strongly opposed the opening of the Straits and England no less strongly advocated it The reason for this complete reversal of traditional policies lay in the altered political and military situation in the Near East effected by the war. Russia was temporarily rendered powerless to threaten Great Britain in the Mediterranean, while the opening of the Straits to warships enabled Great Britain to intervene in the civil war in Russia.

The emergence of the new nationalist Turkish State at Angora also modified the situation. For the first time in the long history of the Straits Question it was the Turks who virtually dictated the new regulations regarding the passage of the Straits. The regulations dictated by the allies in the still-born treaty of Sèvres were so whittled down by Nationalist Turkey as to become practically valueless. The commission for the regulation of the Straits was reduced to little more than a conservancy board under Turkish chairmanship; Turkey was accorded the right (denied her in the Sèvres treaty) to possess a fleet, she was allowed to maintain a garrison in Constantinople; and the demilitarized zones on either side of the Straits were both reduced in area and closed to the military forces of the allies as well as of Turkey—thus removing the one positive military sanction for Turkey's observance of the regulations The three chief European allied Powers and Japan undertook to guarantee the freedom of navigation and the security of the demilitarized zones in return for the concession by Turkey of a restricted right of passage for warships. Against the regime thus set up, the Russian Government protested very strongly; but nevertheless became a party to the convention on Aug. 4, 1923. The regime, however, obviously depended for its further existence upon the weakness in naval strength of Russia

BIBLIOGRAPHY.—The best general sketch (although not wholly accurate and sometimes tendencious), is that by the former Director of the Russian Imperial Archives, S. Goriainow, *Le Bosphore et les Dardanelles* (French trans, 1910) Since the opening of the German and Austrian archives various fully documented studies of single episodes have appeared. Thus A Hasenclever, *Die Orientalische Frage in den Jahren 1838–1841* (Leipzig, 1914); K. Rheindorf, *Die Schwarze Meer (Pontus)-Frage 1856–1871* (1925); H. T. von Falkenstein, *Bismarck und die Kriegsgefahr des Jahres 1887* (1924). Among general works may be mentioned, R. Pinon, *L'Europe et l'Empire Ottoman* (1917); N. Dascovici, *La Question du Bosphore et des Dardanelles* (Geneva, 1915); C. Phillipson and N. Buxton, *The Question of the Bosphorus and Dardanelles,* a study of the question from the aspect of international law (1917). (I. F. D. M.)

STRAITS SETTLEMENTS, the collective name given to the Crown colony formed by the British possessions on or adjacent to the mainland of the Malay peninsula, as opposed to the Federated and Unfederated Malay States, the British protector-

ates in the same region. The Straits Settlements consist of the island of Singapore with about a score of islets of insignificant size lying in its immediate vicinity, of the town and territory of Malacca, the islands and territory of the Dindings, the island of Penang, sometimes officially called Prince of Wales island, and Province Wellesley.

The colony of the Straits Settlements is administered by the governor with the aid of an executive council, composed of official and unofficial members, and there is a legislative council, composed partly of official and partly of unofficial members, of whom the former have a narrow permanent majority. The governor of the Straits Settlements is also high commissioner for the Federated Malay States of the peninsula, for British North Borneo, Brunei and Sarawak in Borneo, and since the administration of the colony of Labuan, which for a period was vested in the British North Borneo company, has been resumed by the British Government, he is also governor of Labuan. The Cocos Keeling islands (which were settled and are still owned by a Scottish family named Ross) and Christmas island were formerly attached to Ceylon, but in 1886 the care of these islands was transferred to the Government of the Straits Settlements. Penang and Malacca are administered, under the governor, by resident councillors British residents administer the native States of Perak, Selangor, Negri Sembilan and Pahang, but since July 1, 1896, when the federation of these States was effected, a resident-general (now styled chief secretary) responsible to the high commissioner, has been placed in charge of all the States forming the federation. The work of administration, both in the colony and in the Federated Malay States, is carried on by a civil service whose members are recruited by competitive examination held annually in London.

The following are the area and population, with details of race distribution, of the colony of the Straits Settlements, the figures being those of the census of 1921:—

its problems for the community. It was necessary to establish a censorship, and in June 1919 an anti-Japanese boycott resulted in rioting in Singapore and Penang.

The export trade of the colony depends primarily upon tin and rubber. The British Malay territories produce nearly half the world's yield of tin ore (the Federated Malay States yielding the great bulk), and more than half the smelted tin. Smelting is carried on at Pulau Brani, near Singapore, and at Penang, ore being imported not only from the Federated Malay States but also from the Dutch islands (Banka, etc.). Tin was more early developed than rubber, mainly, in the first instance, by Chinese enterprise. The production of rubber was not large until 1909–10.

The reaction from prosperity which began to affect world commerce after 1920 struck at the tin and rubber trades of the colony and Malay States. The assistance of the Government was necessary for both. Tin was purchased by the Government at agreed prices, and the stock for which there was no immediate market was brought into the so-called Bandoeng pool, formed in co-operation with the Government of Netherlands India on behalf of the mining industry of Banka and other Dutch islands; the stock thus retained was disposed of by 1924–25 as prices revived. The output of rubber was restricted by legislation in concert with the Government of Ceylon, on the basis of the Stevenson scheme. Restriction, however, was removed in 1928.

Traders have been encouraged to develop a wide range of products. Rice, fish, areca nuts, sago, copra, pepper and preserved pineapples are among the exports. In 1925 the fisheries department started research, with a shore institution and a trawler, into the possibilities of extending the fish trade. The value of exports for Malaya as a whole in 1926 was £148,095,-402; and that of imports was £122,381,054. The revenue of the colony amounted to £4,284,818, and the expenditure to £4,609,-998 in 1926. The value of the dollar is fixed at 2s. 4d.

	Area in square miles	Population in 1891	Population in 1921						
			Total	Europeans	Eurasians	Chinese	Malays	Indians	Other nationalities
Singapore	206	184,554	425,912	6,231	5,451	317,491	58,520	32,456	5,763
Penang, Province Wellesley and Dindings	381	235,618	304,335	1,476	1,919	135,288	110,382	53,339	1,931
Malacca	659	92,170	153,522	442	1,768	45,768	86,451	18,833	260
Total	1,246	512,342	883,769	8,149	9,138	498,547	255,353	104,628	7,954

The population, which in 1867 was 283,384, was estimated at 1,025,835 in 1926. The birth-rate in 1926 was highest among the Chinese. The total death-rate, 27·26 per 1,000 in 1925, was the lowest on record; the death-rate per 1,000 among Europeans was 7·82. Malaria remains a prolific, though diminishing, cause of death; as for beri-beri, the deaths were reduced from 2,056 (with a total population of 705,405) in 1911, to 910 in 1924 and 1,098 in 1926, owing probably, in part, to a better understanding of dietary requirements. Chinese immigrants reached maximum numbers in 1926 (348,593) exceeding emigrants by 228,285; 95,715 were women and children, a record number, and their coming commonly implies intention to settle permanently. An increase of immigration in recent years is due partly to improvement in commerce, but partly also to the disturbed conditions in southern China. Immigrant Indians arrived at Penang to an average yearly number of 54,000 in 1921–24; the numbers fluctuate with the conditions of trade. In 1926 they numbered 174,-795 (*see* MALAY STATES, FEDERATED).

There was an increase in the gross value of trade from £63,-600,000 in 1914 to £148,200,000 in 1917. The Chinese community was prosperous during the World War, and while the increased cost of living and the high rate of exchange with China bore hardly upon the poorer classes, the increase of wages counterbalanced these disadvantages. The Chinese freely supported patriotic and charitable funds, and after some demur, before its purpose was fully understood, recognized without further difficulty the War tax ordinance of 1917. The War produced

The centenary of the modern foundation of Singapore by Sir Stamford Raffles was the occasion for local celebrations in Feb. 1919, and by way of commemoration it was decided to found a Raffles college for higher education. Evidence of the general enthusiasm for this scheme was given by the prompt subscriptions which ensured its success. The Straits Settlement Government promised a donation of $1,000,000 and a site; the same Government and those of Johore and Kelantan guaranteed annuities in perpetuity amounting to $63,000, and by the Governments of the Federated Malay States and Kedah, and from various private sources, annuities for a term of years, amounting to $655,000, were promised. Designs for the new buildings were adopted in 1924, and the erection of science and administrative blocks, a hostel and staff quarters is nearly completed. The Rockefeller Foundation in 1924 granted an endowment of $350,-000 for chairs of bacteriology and biochemistry in King Edward VII. College of Medicine at Singapore, the Government undertaking to bring the provision for these chairs up to the level of others in the college.

The Dindings and Province Wellesley.—The various settlements of which the colony of the Straits Settlements is composed, and the protectorates named in this article, are dealt with separately, except the Dindings and Province Wellesley. The Dindings are sparsely inhabited and unimportant politically.

Province Wellesley, which is situated on the mainland opposite to the island of Penang, was ceded to Great Britain by the sultan of Kedah in 1798. It marches with Perak on the south. It is

administered by a district officer, with some assistants, who is responsible to the resident councillor of Penang. The country consists of fertile plain, thickly populated by Malays, and occupied largely by rubber planters employing Chinese and Tamil labour. About a tenth of the whole area is covered by low hills. Large quantities of rice are grown, and between October and February there is excellent snipe-shooting to be had in the rice-fields. A railway from Prai, opposite to Penang, runs through Province Wellesley into Perak, and thence via Selangor and Negri Sembilan to Malacca, and through Johore to Singapore

STRALSUND, a seaport in the Prussian province of Pomerania, on an arm of the Baltic, 1½ m. wide, which separates the island of Rügen from the mainland, 135 m by rail N from Berlin and 45 m N.W. of Rostock. Pop. (1925), 39,412. A steam railway ferry connects it with the island railway on Rugen, and so with Sassnitz, whence a regular steamboat mail service affords communication with Trelleborg in Sweden.

Stralsund was founded in 1234, and, though several times destroyed, steadily prospered. It was one of the five Wendish towns whose alliance extorted from King Eric of Norway a favourable commercial treaty in 1284–1285; and in the 14th century it was second only to Lubeck in the Hanseatic League. Although under the sway of the dukes of Pomerania, the city was able to maintain a marked degree of independence Its early Protestant sympathies placed it on the side of Sweden during the Thirty Years' War, and in 1628 it successfully resisted a siege of eleven weeks by Wallenstein. After the peace of Westphalia Stralsund was ceded with the rest of Western Pomerania to Sweden; and for more than a century and a half it was exposed to attack and capture as the *tête-de-pont* of the Swedes in continental Europe It was taken by France in 1807, and in 1815 it passed to Prussia

The situation of the town proper, on a small triangular islet only connected with the mainland by three moles and bridges at the angles, has always rendered its fortification comparatively easy Since 1873 the ramparts have been levelled The defences of the place are now solely confined to the island of Dänholm, known down to the 13th century as Strehla or Strehlo, lying in the Sound. Many of the houses present tall, curious and handsome gables to the street. The four Gothic churches of St. Nicholas, with a series of 14th century frescoes, St. Mary, with a lofty steeple, St. James and The Holy Ghost, and the mediaeval town hall, dating in its oldest part from 1306 and restored in 1882, are among the more striking buildings. The latter houses the provincial museum and the municipal library. Among the educational establishments of the place must be mentioned the Gymnasium, founded in 1560, and a school of navigation

STRAMONIUM, in medicine, a drug obtained from the leaves and seeds of the *Datura stramonium.* Both contain the alkaloid daturine. The physiological action of stramonium resembles that of belladonna, except that stramonium relaxes to a greater extent the unstriped muscle of the bronchial tubes; for this reason it is used in asthma to relieve the bronchial spasm. Cigarettes made of stramonium leaves may be smoked or the tincture may be taken internally. Frequently equal quantities of the powdered leaves of stramonium, *Cannabis Indica* and lobelia mixed with potassium nitrate are burned in an open dish. The preparation gives off dense fumes which afford great relief

STRANDLOOPER. The term "Strandlooper" is applied to the extinct people whose remains are found in caves, shelters and kitchen-middens along the eastern coast of southern Africa from Cape Town to Port Elizabeth. They were probably the purest variety of Bushmen (*q v*).

STRANG, WILLIAM (1859–1921), Scottish painter and engraver, was born at Dumbarton, N.B., on Feb. 13, 1859, the son of Peter Strang, builder. In 1875 he went to London, where he studied under Legros at the Slade School for six years. He became assistant master in the etching class, and was one of the original members of the Royal Society of Painter-Etchers, exhibiting at their first exhibition in 1881. In his imaginative etchings he achieved almost painfully realistic effects without sacrificing anything of his fine, clean drawing and severity of design. He worked in many manners—etching, dry-point, mezzotint, sand-ground mezzotint—and invented a burin of his own for burin engraving.

His portrait etchings introduced a new form of reproductive portraiture, each proof being in a sense an original Thomas Hardy, Henry Newbolt and Rudyard Kipling are among the many distinguished men who sat to him for these plates. Strang's paintings, portraits, nude figures in landscapes, and groups of peasant families have been exhibited in the Royal Academy, the International Society and several German exhibitions. In 1902 Strang retired from the Society of Painter-Etchers as a protest against the inclusion in its exhibitions of etched or engraved reproductions of pictures He afterwards exhibited chiefly at the "Society of Twelve," the International Society of Sculptors, Painters and Gravers, and the Royal Academy. He was a member of the International Society, and became, in 1906, an A R.A. for engraving, on the revival of that degree, and in 1921 R.A (Engraving). In 1918 he was made president of the International Society. He died at Bournemouth on April 12, 1921

Strang's engraved work includes "Tinkers", "St Jerome", "A Woman washing her feet", an "Old Book-stall with a man lighting his pipe from a flare," the "Head of a Peasant Woman" (on a sand-ground mezzotint), "Hunger", "the Bachelor's End" and "The Salvation Army" Among his sets of etchings are the "Pilgrim's Progress," the "Ancient Mariner", his own "Allegory of Death" and the "Plowman's Wife"; in collaboration with J B Clark he illustrated *Baron Munchausen, Sindbad the Sailor,* and *Ali Baba* Proofs from his portrait plates have great value In the Tate Gallery, London, are two self-portraits and a landscape A collection of 136 etchings is in the British Museum The catalogue of his etched work, containing small representations of all his plates (747) was published in 1906 (supplements in 1912 and 1923).

STRANGE, SIR ROBERT (1721–1792), Scottish line engraver, was born in Orkney on July 14, 1721, and was apprenticed in 1735 to Richard Cooper, a line-engraver in Edinburgh, afterwards starting on his own account as an engraver in 1741 In 1745 he joined the Jacobite army, and fought at Culloden He superintended the illustrations of Dr. William Hunter's *Gravid Uterus,* and by his plates of the "Magdalen" and "Cleopatra," engraved after Guido in 1753, established his reputation. In 1760 Strange travelled in Italy, and received many distinctions on the Continent. In 1766 he was elected a member of the Incorporated Society of Artists In 1775 he published an attack on the Royal Academy (which excluded engravers) entitled *An Enquiry into the Rise and Progress of the Royal Academy of Arts at London.* He was knighted in 1787 and died in London on July 5, 1792.

STRANRAER, a royal and police burgh, parish and seaport of Wigtownshire, Scotland Pop. (1921), 6,138. It is situated at the head of Loch Ryan, an arm of the North channel (Irish sea), 59 m. S S W of Ayr by the L M.S. railway, with a station in the town and at the harbour It lies 39 m. E. by N. of Larne in Co Antrim, Ireland, with which there is daily communication by mail steamer. Stranraer, originally called St. John's Chapel, became a burgh of barony in 1596, and a royal burgh in 1617. In the centre of the town are the ruins of the castle of the 15th century, occupied for a time by John Graham of Claverhouse, Viscount Dundee, when he held the office of sheriff of Galloway (1682). Grain-milling and nursery-gardening are carried on, and there is a large trade in farm and dairy produce. Harbour accommodation has been extended and steamers run twice daily to Larne in Ireland. There are fine oyster beds, and whitefish and

herrings are caught. Three miles east of Stranraer is Lochinch, the residence of the earl of Stair, a modern structure in the Scots Baronial style. The grounds include the White and Black Lochs and the ruins of Castle Kennedy, finely situated on the isthmus between the lakes. This castle was erected in the reign of James VI. for the earls of Cassilis, and passed into the hands of the Stair family in the 17th century. It was burned down in 1716 and never rebuilt.

STRAP WORK, in architecture and the decorative arts, a form of ornament developed in Germany, Flanders and England during the latter half of the 16th and the 17th century and consisting of scrolls, straight lines, rectangles and shield forms carved or modelled in flat relief, often with a raised fillet at the edge, and often pierced with circular or oval holes; the whole composition is usually formed of connected units, all upon the same plane, as though made by an elaborately cut out and pierced strap applied to a background. It is a development of certain Italian early Baroque motives, such as the multiple shield or cartouche frames, and certain approximations of it occurred in Italian metal-work as early as the silver work of Benvenuto Cellini (1500–71); these forms are, themselves, Italian interpretations of the flat scrolls so common in Mohammedan metal-work. Strap work was used extensively in the Renaissance woodwork of Germany and is occasionally found in stone, as in the Salzhaus at Frankfurt A.M. (end of the 16th century). In Flanders and the Netherlands strap work received an even more complete development, for although in Germany it was usually only a subsidiary motive, in the architectural woodwork and furniture of the Low Countries it often became the only type of ornament used. The form was introduced into England by the flood of Flemish and German woodworkers that came in in the latter part of the 16th and early 17th centuries. (T. F. H.)

STRASBOURG (STRASSBURG), a town of France, the capital of the department of Bas-Rhin, at the junction of the Ill and the Breusch, 2 m. W. of the Rhine, 88 m. by rail N. from Basle. Pop. (1926) 164,136. The Ill divides into arms forming an island on which the city grew; it was long a strongly fortified place and the removal of the fortifications immediately around the city has given opportunities of large expansion in the last half century. The old city contains the cathedral, or Münster (11th to 15th centuries). Part of the crypt dates from 1015; the apse is Transitional; and the nave, finished in 1275, is pure Gothic. The elaborate west façade has a screen of double tracery, numerous sculptures and two towers, the northern with a tall spire. The cathedral has some fine stained glass, a sculptured pulpit and the famous astronomical clock in the south transept; this contains some fragments of the clock built by the mathematician, Conrad Dasypodius, in 1574. The Protestant church of St. Thomas is a Gothic building of the 13th and 14th centuries.

The Palais de Rohan or old episcopal palace, built in 1731–41, was used for university purposes from 1872 to 1895; it is now the municipal museum of art. Other notable buildings are the Frauenhaus, with some interesting sculptures, and the Hôtel du Commerce, the finest Renaissance building in the town. The University of Strasbourg, founded in 1566 and suppressed during the French Revolution as a stronghold of German sentiment, was reopened in 1872 and again as a French institution in 1922.

The chief industries of Strasbourg are tanning, brewing, printing and the manufacture of metal goods, paper and tobacco. To these must be added the fattening of geese for Strasbourg's celebrated *pâté de foie gras*.

History.—Strasbourg has always been a place of great strategical importance, and as such has been strongly fortified. The pentagonal citadel constructed by Vauban in 1682–84 was destroyed during the siege of 1870. The site of the town was originally occupied as a Celtic settlement, which was captured by the Romans, who replaced it by the fortified station of *Argentoratum*, afterwards the headquarters of the eighth legion. In 357 the emperor Julian gained here a decisive victory over the Alamanni, who 50 years later re-conquered the whole of the district. Towards the end of the 5th century the town passed to the Franks, who gave it its present name. The famous "Strassburg oaths" between Charles the Bold and Louis the German were taken here in 842, and in 923, through the homage paid by the duke of Lorraine to the German king Henry I., began the connection of the town with the German kingdom which lasted for over seven centuries. The early history of Strasbourg consists mainly of struggles between the bishop and the citizens. This conflict was finally decided in favour of the citizens by the battle of Oberhausbergen in 1262, and the position of a free imperial city which had been conferred upon Strasbourg by the German king, Philip of Swabia, was not again disputed. In 1332 there was an internal revolution, which admitted the gilds to a share in the government of the city.

In 1381 the city joined the Städtebund, or league of Swabian towns, and a century later it helped the Swiss confederates at Granson and Nancy. The reformed doctrines were readily accepted in Strasbourg about 1523, and the city was skilfully piloted through the ensuing period of religious dissensions by Jacob Sturm von Sturmeck, who secured for it very favourable terms at the end of the war of the league of Schmalkalden. In the Thirty Years' War the town observed a prudent neutrality. In 1681, during a time of peace, it was suddenly seized by Louis XIV., and this unjustifiable action received formal recognition at the Peace of Ryswick in 1697. At the French Revolution the city was deprived of its privileges as a free town. In the war of 1870–71 Strasbourg, with its garrison of 17,000 men, surrendered to the Germans on Sept. 28, 1871. The city and the cathedral suffered considerably from the bombardment.

The bishopric of Strasbourg existed in the days of the Merovingian kings, being probably founded in the 4th century, and embraced a large territory on both banks of the Rhine, which was afterwards diminished by the creation of the bishoprics of Spires and Basel. The bishopric was in the archdiocese of Mainz and the bishop was a prince of the empire. The episcopal lands were annexed by France in 1789 and the subsequent Roman Catholic bishops of Strasbourg discharged spiritual duties only.

Strasbourg is the seat of a bishop, of a prefect and of the departmental organization, and of the special Government offices for the territories returned to France after 1918. Kehl, with a population (1925) of 9,467, on the German bank of the Rhine, opposite Strasbourg, was constituted one with the port of Strasbourg for purposes of exploitation for a period of seven years from 1919. Extensive improvement schemes were approved in 1924, including the creation of a large port above Strasbourg, connecting with the harbour by canal, and a petroleum harbour below the town. (X.)

Battle of Strasbourg (A.D. 357).—A rising of the Sarmatians, Suevi and Quadi on the Danube compelled the Emperor Constantius to hasten there in 357. Julian, the Caesar, was at Sens with an army 13,000 strong, and as the emperor was unable to assist him he despatched Barbatio, *magister peditum* and 25,000 troops to Gaul. Julian was to march north, and Barbatio to co-operate with him with Basel as his base of operations. The forces of the barbarians were to be enclosed between them.

Moving to Reims, Julian concentrated his forces. Thence he marched to Zabern. Meanwhile Barbatio who had refused to obey his orders was surprised by the Germans and driven back to Basel. Julian's position was now an extremely dangerous one; he was far distant from the emperor, and Barbatio's defeat had raised the *moral* of the Germans who, under the leadership of Chnodomar, crossed the Rhine and encamped on its left bank near Strasbourg. Undaunted by this mishap Julian set out from Zabern to meet the horde, which was some 35,000 strong. The Romans marched in close order and in two columns, the cavalry on the right and the infantry on the left, and as evening was approaching Julian was desirous of deferring the battle until the following day. His men, in spite of the heat and the long march, urged him to lead them on. This Julian agreed to, and took command of the right wing consisting of heavy cavalry and archers. This wing coming into contact with the barbarians was fiercely charged by light horse and driven back. A panic was only stayed by the Caesar riding amongst his men and exhorting them to rally. The brunt of the attack was borne by the Roman centre and the left, and it was a struggle of footmen against footmen. In spite of the valour

of the barbarians, the discipline of the Roman infantry carried the day, the Germans being driven into the Rhine where large numbers perished; 6,000 dead were also left on the field. Chnodomar was captured and sent a prisoner to Constantius.

This victory resulted in the recovery of the upper Rhine, and the freeing of Gaul from barbarian invasions.

STRATA-FLORIDA (*Ystradflur*), the ruins of a Cistercian abbey of Cardiganshire, Wales, near the river Teifi, 2 m. from the village of Pontrhydfendigaid (bridge of the blessed ford) on the Teifi. Excavations have brought to light encaustic tiles. The elaborate western portal is a fine specimen of transitional Norman-Irish 12th century architecture. A silver seal of the abbey is in the British Museum. Founded and endowed in 1164 by Rhys ap Griffith, prince of South Wales, the Cistercian abbey of St. Mary (which was probably a revival of an older monastic house on or near the same site) was much favoured by Welsh bards, nobles and princes. In 1138 Llewelyn ap Iorwerth, "the Great," summoned his vassals to this spot to do homage to his heir, Prince David II. The abbey suffered severely during the Edwardian wars, and in or about 1294 a large portion of its buildings was destroyed by fire. Edward I. helped to restore the fabric.

STRATEGUS, strictly a general, but frequently the name of a state officer with much wider functions (στρατηγός) found in many Greek states. The best known is the Athenian strategus, originally a military official, who, in the latter half of the 5th century B.C., became the most important executive magistrate in the state: it is certain that until the end of the 6th century the archon (*q v.*) was the most important state official. The Strategia (board of ten generals) was a result of the tribal system of Cleisthenes. Some maintain that Cleisthenes himself created it, but the evidence (*Ath Pol.* xxii.) is against this. At all events, as late as the battle of Marathon the head of the army was the polemarch. (*See* ARCHON.) It follows that the strategus was, until 487 B C, subordinate to the polemarch, the story of successive days of command in Herodotus being due to a misunderstanding of the powers of the strategi at the time (*cf.* G. B. Grundy, *The Great Persian War*). The tribal unit was represented in the army by the *taxis,* and each *taxis* was led by a strategus. After the Persian wars the command of the *taxis* passed to officers called taxiarchs, who acted as colonels under the strategi. It was the customary practice in the 5th century to appoint a certain number of the generals, usually three or five, for a particular field of operations, and to assign the chief command to one of them. Exceptions to this rule are found in the well-known instances of the Sicilian expedition (when the three commanders, Nicias, Alcibiades and Lamachus were given co-ordinate powers), and the battle of Arginusae, when the command was divided among the whole board. In crises such as the Samian revolt, the outbreak of the Peloponnesian War, or that which led to the recall of Alcibiades, we find the whole board subordinated to a single member (*e g.,* Pericles or Alcibiades). Originally each strategus was elected by and out of the tribe he commanded (*Ath. Pol.* lxi.). In the 4th century, however, the strategi were elected out of all the citizen body irrespective of tribes; in 433, one of Pericles' colleagues was Diotimus, a member of his own tribe (*cf.* Alcibiades and Adeimantus in 408 B.C). But from Xenophon (*Memorab.* iii. 4) we learn that one strategus was still elected by each tribe, *i.e.,* each strategus represented a tribe, though he might not be a member of it. Though the strategi were the nominal heads of the army, they had no power to choose their taxiarchs, who were elected by the tribes. It was only the *lochagoi* (commanders of λόχοι, companies) that the Ecclesia allowed them to select.

In the course of the 5th century the powers of the strategia were increased by important political functions, especially in foreign affairs; hence the office, unlike that of the archon (*q.v.*), remained elective and was held by the most important men (*e.g.* Pericles, Nicias, Alcibiades). As the Boulē was the chief administrative body, it was necessary to bring the strategi into close connection with it, though not members, they were allowed to attend its meetings and to bring motions before it. As the Boulē of one year rarely contained members of the previous Boulē, the strategi acquired great power from the fact that they were frequently re-elected for many years together, and so had greater experience and continuity of policy. In the Ecclesia, the strategus' business took precedence (the meetings always discussed first the question of national defence), and he could, in cases of emergency, convene a special meeting (*cf.* Thuc. ii. 59 and iv. 118).

The strategia was by no means analogous to the British cabinet which has collective responsibility and whose members are heads of state departments The strategi had no collective responsibility, and their appointment for special duties (ἐπὶ τοὺς ὁπλίτας, ἐπὶ τὴν ἀκτήν, κ.τ.λ.) dates from the 4th century. Without being actually a foreign office, they acted on ψηφίσματα of the Ecclesia in negotiating and concluding treaties and alliances Their real power was mainly due to two considerations. They were elected, when other great officials were chosen by lot and thus were picked men approved by the Ecclesia. They were capable of re-election and a man who commanded the confidence of the people was often re-elected (*e.g*, Pericles). Such magistrates gained wide administrative experience and enjoying the confidence of the Ecclesia were able to dominate their colleagues and the state (λόγῳ μὲν δημοκρατία ἔργῳ δὲ τοῦ πρώτου ἀνδρὸς ἀρχή). It was to this personal ascendancy and hold over the Ecclesia rather than to the constitutional authority of his office that the power of the great strategus was due

STRATEGY. The term in its original and literal sense means "the art of the general" (Greek στρατεγος). But no military term, perhaps no technical term of any kind, has undergone more changes of meaning, suffered more attempts to reach a standard definition, or been more diversely interpreted And rarely has a difficulty of definition had such an effect on the course of history For the vagueness which has surrounded the term has influenced the issue of wars and the destiny of nations by encouraging doubt and dissension as to the respective spheres of the military command and the government in time of war.

Change of Meaning.—The word "strategy" as a technical term appears in European military literature early in the 18th century, when the great impetus to military studies given by the wars of the 17th was crystallizing into the formation of academic, and often pedantic schools of thought and theory The conditions of warfare at that period helped to preserve to the term its strict sense, even a straitened sense. These conditions comprised the uniformity of armaments; the superior development of fortification (*q.v.*) to weapons; the professionalization of armies—which complicated their systems of supply and made them instruments too expensive to be employed carelessly or wastefully; the fact that wars were often waged for limited political objects, aiming at extension of territory or power, and controlled by shrewd calculation of the price worth paying, rather than national life and death struggles with passion dominating reason Last, and above all, the indivisibility of armies—which usually fought and moved as a solid block, making temporary detachments to carry out special missions and to hold strategic points, but not organized in permanently self-contained fractions.

These conditions tended to produce an equilibrium in the theatre of war, and on the battlefield, which easily settled into a stalemate unless upset by some ruse or stratagem on the part of one of the commanders. But the French Revolutionary and Napoleonic Wars brought about an enlargement of the meaning of "strategy"—at first called *stratégique* in French or "strategics" in English The fractioning of the army into permanent divisions and Napoleon's development of this new organization, applied in his vast strategic manoeuvres, caused a great acceleration and enlargement of operations. To regulate and co-ordinate the movements of a number of widely separated columns to a common end was a task which both enlarged the power of generalship and the demands made upon the general's attention. Hence this "logistical" meaning, that of directing the movements of an army,

came to be added to the term strategy, and even to overshadow the older meaning. One effect, not a happy one, can be traced in the growing 19th century tendency for the idea of the application of force, as rapidly and concentratedly as possible, to obsess military thought and leadership to the undue neglect of the subtler art of surprise by ruse and stratagem.

But the term was to undergo still further expansion of meaning in the 19th century. Clausewitz in his monumental work "On War" defined it as "the art of the employment of battles as a means to gain the object of the war. In other words, strategy forms the plan of the war, maps out the proposed course of the different campaigns which compose the war, and regulates the battles to be fought in each." This definition intruded on the sphere of policy, or the higher conduct of the war, which must necessarily be the responsibility of the government and not of the military leaders it employs as its agents in the executive control of operations. At the same time the definition narrowed the meaning of "strategy" to the pure utilization of battle, thus conveying the idea that battle was the only means to the strategical end. It was an easy step for his less profound disciples to confuse the means with the end and to reach the conclusion that in war every other interest and consideration should be subordinated to the aim of fighting a decisive battle.

Relation to Policy.—To break down the distinction between strategy and policy would not matter much in cases where the two functions were combined in the same person as with a Frederick or a Napoleon. But as such autocratic soldier-rulers have always been rare, and became extinct in the 19th century, the effect was insidiously harmful. For it encouraged soldiers to make the preposterous claim that policy should be subservient to their conduct of operations and, especially in democratic countries, it drew the statesman on to overstep the indefinite border of his sphere and interfere with his military employee in the actual use of his tools.

Moltke reached a clearer, and wiser, definition in terming strategy "the practical adaptation of the means placed at a general's disposal to the attainment of the object in view." This definition fixes the responsibility of a military commander to the government by which he is employed. His responsibility is that of expending most profitably to the interest of the higher war policy the force allotted to him within the theatre of operations assigned to him. If he considers that the force allotted is inadequate for the task indicated he is justified in pointing this out, and if his opinion is overruled he can refuse or resign the command, but he exceeds his rightful sphere if he attempts to dictate to the government what measure of force should be placed at his disposal.

On the other hand the government, which formulates war policy, and adapts it to conditions which often change as a war progresses, can rightly intervene in the strategy of a campaign not merely by replacing a commander in whom it has lost confidence but by modifying his object according to the needs of its war policy. While it should not interfere with him in the handling of his tools it should indicate clearly the nature of his task. Thus strategy has not necessarily the simple object of seeking to overthrow the enemy's military power. When a government appreciates that the enemy has the military superiority either in general or in a particular theatre, it may wisely enjoin a strategy of limited aim. It may desire to wait until the balance of force can be changed by the intervention of allies or by the transfer of forces from another theatre. It may desire to wait, or even to limit its military effort permanently, while economic or naval action decides the issue. It may calculate that the overthrow of the enemy's military power is a task definitely beyond its capacity, or not worth the effort, and that the object of its war policy can be assured by seizing territory which it can either retain or use as bargaining counters when peace is negotiated. Such a policy has more support from history than military opinion recognizes and is less inherently a policy of weakness than its apologists imply. It is, indeed, bound up with the history of the British Empire and has repeatedly proved a life-buoy to Britain's allies and a permanent benefit to herself. However unconsciously followed, there is ground for enquiry whether this unmilitary policy does not deserve to be accorded a place in the theory of the conduct of war.

But the more usual reason for adopting a strategy of limited aim is that of awaiting a change in the balance of force, a change often sought and achieved by draining the enemy's force, weakening him by pricks instead of risking blows. The essential condition of such a strategy is that the drain on him is disproportionately greater than on oneself. The object may be sought by raiding his supplies, by local attacks which annihilate or inflict disproportionate loss on parts of his force, by luring him into unprofitable attacks, by causing an excessively wide distribution of his force and, not least, by exhausting his moral and physical energy. Such a strategy is popularly called Fabian, after the illustrious Roman who thereby thwarted Hannibal's designs in Italy. More strictly it was a Fabian war policy, and this closer definition sheds light on the question, previously raised, of a general's independence in carrying out his own strategy inside his theatre of operations. For if the government has decided upon a Fabian war policy the general who, even within his strategic sphere, seeks to overthrow the enemy's military power may do more harm than good to the government's war policy. Usually a war policy of limited aim imposes a strategy of limited aim, and a decisive aim should only be adopted with the approval of the government which alone can decide whether it is "worth the candle."

Scope of Strategy.—The nature of war, the objects for which it is waged, and the policy which should govern the conduct of war, are outside the scope of this article. These subjects are dealt with in the article WAR, and for more extensive analysis the reader may be referred to Clausewitz's volumes "On War," a great, if one-sided, work, whose survey has in recent times been enlarged by Fuller's brilliant and profound analysis, entitled "The Foundations of the Science of War."

Strategy covers the distribution and transmission of military means to fulfil the ends of policy. It is concerned not merely with the movements of armies—as its role is often defined—but with the effect. But when the application of the military instrument merges into actual fighting, the dispositions for and control of such direct action are termed "tactics" (*q.v.*).

The two categories, however, although convenient for discussion, can never be truly divided into separate compartments because each not only influences but merges into the other. Nor has clear thought been assisted by the attempts to subdivide into, or to bridge the indefinite dividing line by, fresh categorical definitions. First among these was the term "grand tactics," which came into use in the late 18th century to express the combination and movements of forces preparatory to, and in readiness for, the battle. This term likewise has undergone changes of meaning, and is often employed to denote the plan upon which the application of force, as distinct from other agencies, is to be based. It embraces the combined use of armies, navies and now air forces, but excludes economic or political instruments.

A term which fills a greater need, and is less productive of confusion, is that of "grand strategy." If practically synonymous with the policy which governs the conduct of war, as distinct from the permanent policy which formulates its object, the term "grand strategy" serves to bring out the sense of "policy in execution." For the role of grand strategy is to co-ordinate and direct all the resources of a nation towards the attainment of the political object of the war—the goal defined by national policy.

Grand strategy should both calculate and develop the economic resources and man-power of the nation in order to sustain the fighting services. So also with the moral resources—for to foster and fortify the will to win, and to endure, is as important as to possess the more concrete forms of power. And it should regulate the distribution of power between the several services, and between the services and industry. Nor is this all, for fighting power is but one of the instruments of grand strategy. It should take account of and apply the power of financial pressure, diplomatic pressure, commercial pressure, and, not least, ethical pressure to weaken the opponent's will. A good cause is a sword as well as a buckler. Furthermore, while the horizon of strategy is

bounded by the war, grand strategy looks beyond the war to the subsequent peace. It should not only combine the various instruments, but so regulate their use as to avoid damage to the future state of peacefulness, secure and prosperous. Little wonder that, unlike strategy, the realm of grand strategy is for the most part *terra incognita!*

Pure Strategy.—Having cleared the ground, we can build up our conception of strategy on its original and true basis—that of "the art of the general." This depends for success, first and most, on a sound calculation and co-ordination of the end and the means The end must be proportioned to the total means, and the means used in gaining each intermediate end which contributes to the ultimate must be proportioned to the value and needs of that intermediate end—whether it be to gain an objective or to fulfil a contributory purpose. An excess may be as harmful as a deficiency A true adjustment would establish a perfect economy of force, in the deeper sense of that oft-distorted military term But, because of the nature and uncertainty of war, an uncertainty aggravated by its unscientific study, a true adjustment is beyond the power of military genius even and success lies in the closest approximation to truth This relativity is inherent because however our knowledge of the science of war, at present an almost unexplored region, be extended, war is a science which depends on art for its application. Art can not only bring the end nearer to the means, but by giving a higher value to the means enable the end to be extended. This complicates calculation, because no man can exactly calculate the capacity of human genius and stupidity nor the incapacity of will

Elements and Conditions.—Nevertheless in strategy calculation is simpler and a closer approximation to truth possible than in tactics For in war the chief incalculable is the human will, which manifests itself in resistance, which in turn lies in the province of tactics Strategy has not to overcome resistance, except from nature Its purpose is to diminish the possibility of resistance, and it seeks to fulfil this purpose by exploiting the elements of movement and surprise. Movement lies in the physical sphere and depends on a calculation of the conditions of time, topography and transport capacity. By transport capacity one implies both the means by which and the measure in which force can be moved and maintained.

Surprise lies in the psychological sphere and depends on a calculation, far more difficult than in the physical sphere, of the manifold conditions, varying in each case, which are likely to affect the will of the opponent.

Although strategy may aim more at exploiting movement than at exploiting surprise, or conversely, yet the two elements react on each other. Movement generates surprise, and surprise gives impetus to movement For a movement which is accelerated or changes its direction inevitably carries with it a degree of surprise, even though it be unconcealed; while surprise smoothes the path of movement by hindering the enemy's counter-measures and counter-movements As regards the relation of strategy to tactics, while in execution the borderline is often shadowy, and it is difficult to decide exactly where a strategical movement ends and a tactical movement begins, yet in conception the two are distinct Tactics lies in and fills the province of fighting Strategy not only stops on the frontier, but has for its purpose the reduction of fighting, to the slenderest possible proportions

Aim of Strategy.—This statement may be disputed by those who conceive the destruction of the enemy's armed forces as the only sound aim in war, who hold that the only goal of strategy is battle, and who are obsessed with the Clausewitzian saying that "blood is the price of victory" Yet if one should concede this point and meet its advocates on their own ground, the statement would remain unshaken. For even if a decisive battle be the only goal, all recognize that the object of strategy is to bring about this battle under the most advantageous circumstances. And the more advantageous the circumstances, the less proportionately will be the fighting.

The perfection of strategy would therefore be to produce a decision—the destruction of the enemy's armed forces through their unarming by surrender—without any fighting History provides examples where strategy, helped by favourable conditions, has practically produced such a result. Caesar's Ilerda (*q.v.*) campaign was one, Cromwell's Preston campaign (*see* GREAT REBELLION) another, while in recent times there have been the operations which culminated at Sedan (*q.v.*) in 1870 and between Galilee and the hills of Samaria in 1918 (*See* PALESTINE, OPERATIONS IN)

It rests normally with the government, responsible for the grand strategy of a war, to decide whether strategy should make its contribution by achieving a military decision or otherwise. And just as the military is but one of the means to the end of grand strategy—one of the instruments in the surgeon's case—so battle is but one of the means to the end of strategy. If the conditions are suitable, it is usually the quickest in effect, but if the conditions are unfavourable it is folly to use it.

Let us assume that a strategist is empowered to seek a military decision His responsibility is to seek it under the most advantageous circumstances in order to produce the most profitable result. Hence his true aim is not so much to seek battle as to seek a strategic position so advantageous that if it does not of itself produce the decision its continuation by a battle is guaranteed to do so. In other words, dislocation is the aim of strategy; its sequel may either be the enemy's dissolution or his disruption in battle. Dissolution may involve some partial measure of fighting but this has not the character of a battle. Famous examples, beyond those already quoted, from history include Hannibal at Trasimenus (*q v.*), Turenne's last campaign in Alsace (*see* DUTCH WARS), and Napoleon's Ulm campaign (*See* NAPOLEONIC CAMPAIGNS.) Among clear cases where disruption was an inevitable sequel to the strategic advantage previously gained one may instance Scipio's campaign of Ilipa (*q.v.*), Cromwell's of Worcester (*q v.* and also GREAT REBELLION), Napoleon's of Jena, Grant's of Vicksburg (*q v.*).

Action of Strategy.—How is the strategic dislocation produced? In the physical, or "logistical," sphere it is the result of a move which (a) upsets the enemy's dispositions and by compelling a sudden "change of front" dislocates the distribution and organization of his forces; (b) separates his forces; (c) endangers his supplies; (d) menaces the route or routes by which he could retreat in case of need and re-establish himself in his base or homeland. A dislocation may be produced by one of these effects but is more often the consequence of several Differentiation, indeed, is difficult because a move directed towards the enemy's rear tends to combine these effects. Their respective influence, however, varies and has varied throughout history according to the size of armies and their complexity of the organization With armies which "live on the country," drawing their supplies locally by plunder or requisition, the line of communication has negligible importance Even in a higher stage of development, a small force has less dependence on the line of communication and enables supplies to be transported with it for limited periods The larger an army and the more complex its organization the more prompt and serious in effect is a menace to its line of communication.

Where armies have not been so dependent, strategy has been correspondingly handicapped, and the tactical issue of battle has played a greater part. Nevertheless, even thus handicapped, strategic artists have frequently gained a decisive advantage previous to battle by menacing the enemy's line of retreat, the equilibrium of his dispositions, or his local supplies

To be effective such a menace must usually be applied at a point closer, in time and space, to the enemy's army than a menace to his communications, and thus in early warfare it is often difficult to distinguish between strategical and tactical manoeuvre

In the psychological sphere, dislocation is the result of the impression on the commander's mind of the physical effects which we have listed. The impression is strongly accentuated if his realization of being at a disadvantage is sudden, and if he feels that he is unable to counter the enemy's move. Psychological dislocation, indeed, fundamentally springs from the sense of being trapped. This is the reason why it has most frequently followed a physical move onto the enemy's rear An army like a man can-

not properly defend its back from a blow without turning round to use its arms in the new direction. "Turning" temporarily unbalances an army as it does a man, and with the former the period of instability is inevitably much longer. In consequence, the brain is much more sensitive to any menace to its back. In contrast, to move directly on an opponent is to consolidate his equilibrium, physical and psychological, and by consolidating it to augment his resisting power. In war as in wrestling the attempt to throw the opponent without loosening his foothold and balance tends to self-exhaustion, increasing in disproportionate ratio to the effective strain imposed upon him. Because of this disproportion, which increases as the effort advances, victory by such a method can only be attainable if the assailant possesses a great margin of strength. Even so, it tends to lose decisiveness, for in the case of an army it rolls the enemy back towards their reserves, supplies and reinforcements, so that as the original front is worn thin new layers are added to the back. And, at best, it imposes a strain rather than producing a jar.

Thus a move round the enemy's front against his rear has the aim not only of avoiding resistance on its way but in its issue. In the profoundest sense, it takes the line of least resistance. The equivalent in the psychological sphere is the line of least expectation. They are the two faces of the same coin, and to appreciate this is to widen our understanding of strategy. For if we merely take what obviously appears the line of least resistance, its obviousness will appeal to the opponent also and this line may no longer be that of least resistance. In studying the physical aspect we must never lose sight of the psychological, and only when both are combined is the strategy truly an indirect approach, calculated to dislocate the opponent's equilibrium.

Examples.—Hannibal in 217 B.C. took the line of least resistance and least expectation by moving into Etruria through the marshes and on to the rear of the Roman army encamped at Arretium. But, after ravaging the country, he then moved straight on, and by thus appearing to ignore contemptuously this Roman army impelled the consul Flaminius far more strongly than by any threat to his rear or supplies to rush precipitately on Hannibal's heels and into the deadly ambush at Lake Trasimene (*q.v.*).

Schlieffen, framing the German plan for 1914, sought a logistical indirect approach by sweeping through Belgium with a massive right wing. But the real subtlety of his plan was not on his right but on his left, which he made so weak that any French offensive in Lorraine would push it back. And the further it was pushed back, the further would the French be committed in this direction and the more would their rear be exposed to the sweep of his right wing through Belgium. Like a neck their communications would be stretched out to receive the falling axe. The plan was shrewdly based on an insight into the French temperament and their new doctrine of the headlong offensive. Indeed, in the event the French "head" was laid blindfold on the block. But unfortunately for Germany, Schlieffen's successor, Moltke, failed to grasp his conception and, fearing the weakness of the left wing, so strengthened this as to counteract its essential purpose. While the French rushed to fall into the trap, Moltke rushed German troops to save them. An irony of history.

The Indirect Approach.—Thus we see that the mere fact of marching indirectly towards the enemy and on to the rear of his dispositions does not constitute a strategic indirect approach. Strategic art is not so simple. Such an approach may start by being indirect in relation to the enemy's front, but by the very directness of its progress towards his rear may allow him to change his dispositions so that it soon becomes a direct approach to his new front.
